MATTHEW.

MATTHEW, or *Gospel of St. Matthew*, a canonical book of the New Testament. The writer of this gospel, an apostle and evangelist, surnamed Levi, and son of Alpheus, was, before his conversion to Christianity, a publican, or toll-gatherer under the Romans. He was a native of Galilee, but of what city in that country, or of what tribe of the people of Israel, we are not informed. Jesus found him at the receipt of custom, and called him to be witness of his words and works, thus conferring upon him the honourable office of an apostle. From this time he continued with Christ; and after his ascension, he was at Jerusalem, and partook of the gift of the Holy Ghost, with the other apostles. With them he bore testimony to the resurrection of Jesus; and, as we may reasonably suppose, preached for some time at Jerusalem, and in various parts of Judea, confirming his doctrine with miracles, which God enabled him to perform in the name of Jesus. Socrates, in the fifth century, says, that when the apostles went abroad to preach to the Gentiles, Thomas took Parthia for his lot, Matthew Ethiopia, and Bartholomew India; and it is now a common opinion, that Matthew died a martyr in Ethiopia, in a city called Naddabar, or Naddever; but the mode of his death is not ascertained. Others speak of his preaching and dying in Parthia or Persia; but we may infer from the diversity of these accounts, that none of them are well founded. Heracleon, a learned Valentinian, in the second century, whom Clement of Alexandria has cited, reckons Matthew among those apostles who did not die by martyrdom; nor does Clement contradict him. Chrysostom, though he mentions him with peculiar commendation, and speaks of his "coming from the presence of the council rejoicing," (see Acts, v. 41.) says nothing of his martyrdom. Hence we may infer, that there was not any tradition about it among Christians at that time, or that it was not much regarded.

St. Matthew is said by many to have written his gospel in Judea, at the request of the Jewish believers, when they were likely to be dispersed by persecution; and it is thought by some, as Baronius, Grotius, Vossius, Jones, Wetstein, &c. that he began it in the year 41, eight years after Christ's ascension. But according to others, as Basnage, Dr. Lardner, &c. who follow the testimony of Irenæus, this gospel was written in the time of Nero, about thirty years after our Saviour's ascension, or about the year 63, 64, or 65 of the vulgar epoch. At the year 64, or about that period, the gospel had been propagated in many Gentile countries, the times were troublesome in Judea, and the war was coming on: several of the apostles were dead, others of them, who survived, were going abroad, and many of the Jewish believers were about to seek shelter elsewhere: now, says Dr. Lardner, was a proper time to write a history of Christ, and of his miracles. Moreover in this gospel are recorded divers plain predictions of the miseries and desolations of Jerusalem, and the overthrow of the temple and the Jewish state, besides many other figurative intimations of the same things in many of our Lord's discourses and parables; which could not be well published to all the world in writing till about this time. The suitableness of St. Matthew's gospel to the state of the Christian religion, and of the Jewish people, about the year 64 or 65, leads to that time. And however unwillingly, from private apprehensions and prejudices, we may admit the thought of protracting so long the writing of the history of our Lord's ministry; the circumstances of things, says Lardner, will constrain us to acquiesce in this season as the most likely. Cave thought that it was written about the 15th year after our Saviour's ascension, in the year 48. It was written, according to the testimony of most of the ancients, as Papias, A. D. 116, Irenæus in 178, Origen in 230, Eusebius in 315, Athanasius, Cyril of Jerusalem,

Strahan and Preston,
New-street-Square, London.

Jerusalem, Epiphanius, Gregory Nazianzen, Jerome, Chrysostom, &c. in the Hebrew or Syro-Chaldaic language, which was then common in Judea; but the Greek version of it, which now passes for the original, is said to be as old as the apostolical times. However, many learned moderns, as Fabricius, Erasmus, Lightfoot, Calvin, Le Clerc, Beausobre, Whitby, &c. are of opinion, that this gospel was first written in Greek, which was much used at that time throughout the whole Roman empire, and particularly in Judea: and it is alleged that Papias, who first advanced the contrary opinion, was a weak and credulous man. Jones, Basnage, Lardner, Jortin, &c. are of this opinion. Dr. Lardner observes on this point, that if St. Matthew did not write till about thirty years after our Lord's ascension, which he thinks most probable, he would use the Greek language; but if he wrote his gospel within the space of eight years after Christ's ascension, it is most likely that he wrote in the Hebrew. He adds, farther, that there was very early a Greek gospel of St. Matthew, cited or referred to by Clement of Rome, Ignatius, Polycarp, Justin Martyr, and others, none of whom intimate that they made use of a translation: that many of the ancients do not seem to have fully believed that Matthew wrote in Hebrew, because they have shewn very little regard to the Hebrew edition of it: that there are not in our Greek gospel of St. Matthew any marks of a translation: that there is no where any probable account who translated this gospel into Greek; and besides, as the Greek gospel was translated into Hebrew in very early days of Christianity, many not examining it particularly, nor indeed being able to do it, for want of understanding the language, might imagine, that it was first written in Hebrew. Hence, according to Dr. Lardner, sprung the opinion, that Matthew published his gospel at Jerusalem, or in Judea, for the Jewish believers, and at their request, before he went abroad to other people: whereas he apprehends, that this gospel, as well as the others, were written and intended for believers of all nations; and that the Nazarene gospel was St. Matthew's gospel, translated from Greek, with the addition of some other things, taken from the other gospels, and from tradition. Allowing the date of this gospel already assigned, he cannot conceive the reason why Matthew should write in Hebrew any more than any of the other evangelists; for it may be reckoned highly probable, or even certain, that he understood Greek, before he was called by Christ to be an apostle. Whilst a publican, he would have frequent occasions both to write and speak Greek, and could not discharge his office, without understanding that language.

According to the testimony of Irenæus, all the Jewish believers in general received the gospel of St. Matthew entire, with the genealogy at the beginning: for Irenæus says expressly that Matthew "strove by all means to give to the Jews full satisfaction, that Christ was of the seed of David: wherefore he began with his genealogy." The first chapter of this gospel is quoted by Justin Martyr (A. D. 140) in his First Apology; by Tertullian (A. D. 200), who says that Matthew, "for no other reason than that we might be informed of the origin of Christ according to the flesh, began in this manner:"—"The book of the generation of Jesus Christ, the son of David, the son of Abr ham." Novatus (A. D. 251) several times quotes the first chapter of this gospel. The second chapter is referred to by Ignatius (A. D. 107), and by Hegesippus (A. D. 173), whence we are led to conclude, that this part of St. Matthew's gospel was owned by this Hebrew Christian. Epiphanius, however, informs us, that the gospel of the Ebionites begins thus: "It came to pass in the days of Herod, the king of Judea, that John came baptizing with the baptism of repentance in the river Jordan," which is the beginning of the third chapter of St. Matthew, a little altered: and he says expressly, that their gospel called according to Matthew, is "defective and corrupted." It is nevertheless plain from a passage in Hegesippus, that he received the history in the second chapter of St. Matthew; so that, as Lardner suggests, he used our Greek gospel. Or, if he used only the Hebrew edition of St. Matthew's gospel, this history must have been in it in his time. The first and second chapters of this gospel are referred to in the Sibylline oracles, a work of the second century, according to Lardner: and the second chapter is alluded to by Victorinus (A. D. 290.) Cerinthus, an early heretic, who is supposed to have lived in or near the age of the apostles, made use of the beginning of St. Matthew's gospel, and from thence endeavoured to prove, that Jesus was descended in a natural way from Joseph and Mary. These chapters, however, are of doubtful authenticity, and have been rejected by several ancient and modern writers; and the candid reader must allow that they are liable to various objections. The external testimony against them is strong; and their contents present us with difficulties that are not easily solved. It has been alleged, that though the ancients, with one consent, affirm that the gospel by St. Matthew was originally published in Hebrew or Syro-Chaldaic, some of them represent the copies of it as not having the two first chapters; and this circumstance, it is said, affords a strong presumption against their authenticity. Whether this Syro-Chaldaic or Hebrew gospel be the original copy or not, such a copy certainly existed at a very early period; and its authority must be allowed to have considerable weight in deciding this question; especially when it is considered that we have no *certain* references or allusions to these chapters till the days of Celsus the Epicurean, about the year 150, or later, and of Irenæus, about 178. As to this Hebrew copy, the reception of it by the Ebionites, and perhaps also by the Nazarenes, yields a strong argument in favour of its authority. Epiphanius says, that the Nazarene gospel was πληρεστατον, *i. e.* most entire, but that the Ebionite gospel was ουχ ὁλω πληρεστατον, *i. e.* not altogether entire. The former, it is thought by some, was the true original copy of St. Matthew; and the latter might be, in some degree, corrupted. Irenæus, Eusebius, and Epiphanius say, that the gospel received by the Nazarenes and Ebionites was the gospel of Matthew altered in some particulars, according to their different sentiments. Dr. Lardner adopts this opinion. Dr. Mills thinks, that the Nazarenes and Ebionites had the truest copy of St. Matthew's Hebrew gospel. That this Hebrew gospel was the original of St. Matthew, and that he wrote his gospel in Hebrew, is maintained by Papias, A.D. 116, the disciple and companion of Polycarp; Irenæus, A.D. 148; Tatian, A.D. 172; Hegesippus, A.D. 173; Origen, A.D. 230; Eusebius, A.D. 315; Pantænus, A.D. 192; Cyril of Jerusalem, Epiphanius, Gregory Nazianzen, Jerome, Augustin, Chrysostom, Isidore of Seville, Theophylact, and several other orthodox writers. Nor was this fact questioned, it has been said, till of late; for Erasmus was one of the first, who, in opposition to all antiquity, asserted that Matthew wrote in Greek; and he has been followed by many ingenious moderns; such are cardinal Cajetan, Oecolampadius, Flaccius Illyricus, Calvin, Vossius, and other foreigners, and Dr. Lightfoot, Dr. Whitby, Mr. Jer. Jones, Dr. Lardner, and other English divines.

Those who allow that there was a Syro-Chaldaic gospel of St. Matthew extant in very early times, and that the Nazarenes and Ebionites believed and declared it to be the original

original of St. Matthew, are nevertheless of opinion, that this gospel was originally written in Greek. To this purpose they allege, that the present Greek copy has no mark of a translation; that the Greek was the most proper language, because it was the most universal; and that St. Matthew, who was a publican before he became an apostle, must have been acquainted with it; that if our present copy of St. Matthew's gospel be only a translation, it must be of very doubtful and precarious authority, and that it must appear to be very strange and surprising that this Syro-Chaldaic gospel should be so soon lost, if it had been the work of an apostle. But to return from this digression to the question concerning the genuineness of the two first chapters: it has been urged that these chapters were not referred to for a considerable time after St. Matthew's gospel was publicly known. It is not certain that they are referred to by any of those who are usually called the apostolical fathers, though these fathers frequently refer to other parts of the gospel. Under this class we may comprehend Barnabas, A D 71; Clement of Rome, A.D. 96; Hermas, A.D. 100; Polycarp, A.D. 108. Irenæus, without doubt, acknowledged both the chapters as the genuine production of St. Matthew; so do also Clement of Alexandria, A.D. 194, and Tertullian, A.D. 200; and as we descend to later periods, allusions to them more frequently occur. The first and second chapters of St. Matthew's gospel are inserted in the Syriac version of the New Testament, and this may be considered as a strong argument in favour of their authenticity. The arguments from external testimony against their authenticity may be summed up in the following epitome: we have undoubted evidence that these two chapters were wanting in some very ancient copies of this gospel, which were used by the first Christians; the Ebionites certainly omitted these chapters, and we know that the genealogy was omitted by other Christians, nor have we any reason to think that they were inserted in the Hebrew or Syro-Chaldaic copy, which all the fathers jointly affirm to have been the original of St. Matthew: it is not probable that they would have been expunged, if they had been genuine, because there was but one point, *viz.* our Saviour's birth of a virgin, by which they seemed to oppose the notions of some particular sects of Christians, and that those sects might have overcome the difficulty in a much safer way, by either reasoning, as Cerinthus actually did, from the genealogy, that Jesus was the son of Joseph and Mary; or by receiving St. Mark's gospel, and rejecting St. Matthew's altogether. The collateral arguments against the authenticity of these chapters, deduced from their contents, are such as follow: it has been agreed by many writers, that St. Mark, in most places, agrees with the method and order of both St. Matthew and St. Luke, and so doth also St. John, after a short introduction concerning the Logos. St. Mark begins his gospel at what we call the third chapter of St. Matthew; that is, at the time when John came baptizing in the wilderness. As it is most probable that St. Luke was the first who published a gospel, and as he had given the genealogy, and a full account of the birth, &c. of Christ, there was no necessity for those who came after him to repeat the same things, as they were not particularly important to the virtue and happiness of man, the great end which our Saviour and his disciples had in view. Besides, St. Luke's account of the birth of Jesus, and of all the events which followed it, till Joseph and Mary carried him home to Nazareth, which he has fully detailed, is totally different from that which is found in the first and second chapters of St. Matthew's gospel. No coincidence occurs, except in Christ's being born at Bethlehem of a virgin, and in his dwelling at Nazareth. Hence it is inferred, that the absolute silence of St. Luke, respecting many remarkable events supposed to be related by St. Matthew, yields a strong negative argument against the authenticity of these two chapters. There is also in the contents of these chapters something peculiar both in the sentiments and language, such as does not occur in other parts of the New Testament, chap. i. 20 ii. 12, 13. 19. 22. The appearance of a star in the east, directing the wise men to the new-born Messiah, in Judea, has, it has been said, more the air of an eastern invention than of a real history. In chap. ii. v. 3. a circumstance is mentioned that is scarcely credible, *viz.* that "when Herod the king had heard these things, he was troubled, and *all Jerusalem* with him." Another peculiarity in these chapters is the behaviour of the Magi to the child Jesus; "they fell down and worshipped him," chap. ii. 11. Moreover, Dr. Wall observes, that the account of the genealogy in St. Matthew is the most difficult to reconcile with St. Luke, or with itself, of any place in the gospel: he adds that there are more difficulties in these two chapters than in the whole Bible besides. There are also in these two first chapters several prophecies of the Old Testament, said to be fulfilled, but which cannot easily be made to correspond with the events by which they are declared to be accomplished. (See chap. i. 22, 23. chap. ii. 6. compared with Micah. v. 2.) The slaughter of the infants at Bethlehem, though a very remarkable fact, is not mentioned by any writer but by the supposed St. Matthew in this second chapter, and by those who quote from him. To this is annexed a prophecy, cited from Jerem. xxxi. 15, &c. supposed to relate to a totally different subject. The passage cited from Hosea, xi. 1. does not seem to have the most distant reference to the Messiah. (See ACCOMMODATION.) The flight from Bethlehem seems to have been impracticable; and from Nazareth it was altogether unnecessary, because the slaughter of the infants did not extend so far.

In order to account for the interpolation of these two chapters, without impugning the authenticity of the whole gospel, those who dispute their genuineness, and maintain that the difficulties which they furnish cannot be obviated by the records of history and the aid of criticism, recur to one or other of the following hypotheses. They take for granted that the gospel was originally written in the Syro-Chaldaic language; and that when it was translated into Greek, the body of Christians had little acquaintance with the language of the original, and therefore left the translator at liberty to add, or, if he had been so disposed, to take away what he pleased, without much danger of detection. If the translator was a believing Jew, it is possible that he might think a few prophecies, cited from the Old Testament, by way of accommodation, would have considerable influence upon some of his unbelieving brethren abroad, who, having never seen the original, would naturally think that the Greek copy was, in every respect, a faithful translation of that original. Or, this interpolation might have happened without the least design. These chapters might originally be a kind of introduction to the gospel of St. Matthew, drawn up by the translator of it into Greek, and never intended by him to be considered as a part of it. When the Greek copy of the gospel was spread abroad, those who were unacquainted with the original would naturally think, that, as it was called the gospel by St. Matthew, it contained nothing but the authentic writing of that apostle; and accordingly, it might be received as such in the countries out of Judea. When Origen, Jerome, &c. perceived that these chapters were wanting in the Ebionite gospel, there was nothing unnatural in their supposing, that they were left out with design, because the Ebionites, &c. were then conſidered as heretics, and, of conſequence, capable of any fraud or impoſture. The Greek copy of St. Matthew ſoon gained reputation, becauſe it was uſed by the generality of Chriſtians, whereas the Syro-Chaldaic copy was uſed by only a few poor Jewiſh converts in Paleſtine; and theſe, reputed enemies to the true faith. Hence the former copy would be deemed of much greater reputation than the latter. Upon the whole it ſhould be obſerved, that no doctrine, or fact in Chriſtianity, will be affected by the omiſſion of the firſt and ſecond chapters of St. Matthew; for as to the genealogy, birth, &c. of Chriſt, we have, in St. Luke's goſpel, a full and conſiſtent account of them; whereas theſe chapters contain ſcarcely any thing that is not difficult and liable to objections. We do not, however, think the difficulties incapable of ſolution, nor the objections altogether unanſwerable. Profeſſor Michaelis, in his "Introductory Lectures, &c." ſtates, that if theſe chapters had been wanting in St. Matthew's original text, they ought not to be immediately rejected as an interpolation; for they may have been a ſeparate writing of St. Matthew, deſigned by him to give an account of the childhood of Chriſt, to which he prefixed the title Βιβλος γενεσεως, and to prevent its being loſt as a ſeparate compoſition, the tranſlator, as it related to the ſame ſubject, might join it to the goſpel of St. Matthew. The profeſſor acknowledges the difficulties that occur in theſe two chapters, but he thinks it unwarrantable to reject them on that account. See Williams's Free Enquiry, &c. firſt publiſhed in 1771, and republiſhed with additions in 1789. Michaelis's Introduction to the New Teſtament, by Marſh, vol. iii. part 1.

MATTHEW of Weſtminſter, in *Biography*, an ancient Engliſh chronicler, and Benedictine monk of the abbey of Weſtminſter, flouriſhed in the fourteenth century: he compiled a chronicle in Latin, commencing from the creation, and proceeding down to the year 1307, which was entitled "Flores Hiſtoriarum," hence its author was named "Florilegus." This work related almoſt entirely to Engliſh hiſtory, and is freely tranſcribed from Matthew Paris and others. The writer is applauded for veracity and accuracy, but biſhop Nicolſon holds him up as a mere compiler, without any great degree of judgment. The "Flores Hiſtoriarum," &c. was publiſhed at London in 1567, and again at Frankfort in 1601. It is divided into three books, 1. From the creation to the birth of Chriſt; 2. From that period to the Norman Conqueſt; and 3. From thence to the beginning of Edward II.'s reign. A period of ſeventy years was added by other hands. Gen. Biog.

MATTHEW, *St.*, in *Geography*, an iſland in the Atlantic ocean, diſcovered in 1516 by the Portugueſe, who have a ſettlement on the iſland. S. lat. 1° 45′. W. long. 13°.—Alſo, an iſland in the Indian ſea, near the coaſt of Siam. N. lat. 9° 35′. E. long. 97° 52′.—Alſo, a river of Lower Siam, which runs into the Eaſt Indian ſea, N. lat. 10° 5′.

MATTHEW's *Bay*, *St.*, a bay in the gulf of Mexico, W. of the gulf of Campeachy.—Alſo, a bay called *Mattheo* bay, on the coaſt of Peru, in the North Pacific ocean; ſix leagues to the N.E. by E. from Point Galera, and five or ſix leagues S.S.W. from the river St. Jago, with anchorage all the way.

MATTHEW's, *St.*, *Day*, is a feſtival obſerved on the 21ſt of September.

MATTHEW's *Shoals*, *St.*, in *Geography*, two rocky iſlets ſurrounded with ſhoals, in the Eaſt Indian ſea. S. lat. 5° 14′. E. long. 124° 54′.

MATTHEWS, a county of Virginia, 18 miles long and ſix broad, bounded W. by Glouceſter, N. by Middleſex, E. by the Cheſapeak, and S. by Mobjack bay; 193 miles from Waſhington.

MATTHIAS, St., in *Scripture Hiſtory*, an apoſtle, who was choſen in the room of Judas. He was qualified for the office to which he was appointed, by having been a conſtant attendant on our bleſſed Lord during the courſe of his miniſtry, and was probably one of the 70 diſciples. He preached in Judea and part of Ethiopia, and ſuffered martyrdom. The traditions, and alſo the goſpel of Matthias, are ſpurious. See GOSPEL.

MATTHIAS's *Day*, *St.*, a feſtival of the Chriſtian church, obſerved on the 24th of February.

MATTHIAS, in *Biography*, emperor of Germany, ſon of the emperor Maximilian II. was born in 1557. When he was twenty years of age, he was invited by the revolted ſtates of the Low Countries to take upon himſelf the government of thoſe provinces, which he accepted; appointing the prince of Orange to act as his lieutenant. His power was very circumſcribed, and ſerved only to give a ſort of reputation to the revolters as their nominal head; and in 1581, through the jealouſy of the houſe of Auſtria, he was honourably diſmiſſed. In 1594, he was appointed general of the army which his brother Rodolph II., emperor of Germany, ſent againſt the Turks. In this ſervice he was very ſucceſsful, and ſo well ingratiated himſelf with the Hungarians, that they conferred upon him the moſt diſtinguiſhed honours, and in 1607 elected him their king, on condition that he ſhould confirm all their privileges, and allow the Proteſtants the free exerciſe of their religion. After this he was proclaimed king of Bohemia, in prejudice to his own brother Rodolph, and was crowned at Prague in the year 1611: he had, previouſly to this, obliged his brother to yield him the poſſeſſion of the archduchy of Auſtria: and on the death of Rodolph, in 1612, Matthias was elected to ſucceed him. Such was the rapid elevation of this prince; but ſoon after he ſucceeded to the empire, a diet was convoked at Ratiſbon, at which the Proteſtants agreed to preſent a memorial to the emperor, complaining of his privy-council for interfering in various matters relative to religion, over which they, by right, had no juriſdiction, and making ſeveral demands for the purpoſe of ſecuring to them an equal adminiſtration of juſtice. An evaſive anſwer was given, and the Proteſtants declined giving ſupplies of men and money to the empire till their grievances were redreſſed. The Catholics, on the other hand, recriminated on the Proteſtants, and, during their conteſts, the Turks made an irruption into Tranſylvania. After a variety of fortune, in which Bethlem Gabor took a diſtinguiſhed part, peace was made in 1615, by which the grand ſeignor reſtored to the houſe of Auſtria all the places in Hungary that had been conquered by his arms, and re-inſtated the owners of all lands that had been alienated. Matthias now reſolved to curb his Proteſtant ſubjects; and took meaſures accordingly. The Proteſtants were, however, enabled to procure a convocation of the ſtates, and ſent deputies to renew their remonſtrances before the council. Theſe, being rouſed by the ill treatment which they experienced, could not reſtrain their paſſions, and actually threw ſeveral of the members of the council out of the window; but fortunately no lives were loſt on the occaſion. The count de la Tour, who was the principal actor in this buſineſs, foreſeeing its probable conſequences, perſuaded the Proteſtants to take up arms in their own defence. Matthias ſaw he had carried matters too far, and endeavoured to reclaim them by gentle means; but they returned bold remonſtrances to his declarations, and accuſed his prime miniſter, Kleſel, cardinal and archbiſhop of Vienna, of promoting the perſecutions that they

they had fuftained. The Proteftants of Silefia were equally difcontented, and made an alliance with the Bohemians, who were now in a ftate of actual rebellion. This was the commencement of that thirty years war which defolated Germany, and was productive of fo many great and difaftrous events. Matthias was obliged to banifh his minifters, and the war between the Proteftants and Catholics began with various fuccefs, but in the end Bohemia remained in the power of the Proteftants. Matthias died in 1619, at the age of fixty-three, after a reign of feven years as emperor. He left no legitimate iffue, and recommended moderation to his fucceffor Ferdinand. Univer. Hift.

Matthias Corvinus, king of Hungary, fon of the celebrated Huniades, was a prifoner at his father's death, together with his elder brother Ladiflaus, on account of the fhare which the latter had in the affaffination of the count de Cilley, for which he was afterwards executed. Matthias was detained in cuftody at Vienna, whence he was removed by a counterfeit order to Bohemia. He was ftill held in confinement at Prague, but upon the death of Ladiflaus the Pofthumous, in 1458, he was elected king of Hungary, being then about the age of eighteen. From his very early youth he had manifefted a martial fpirit, and had excelled in warlike exercifes. He could not obtain his liberation from the hands of the governor Podzebrafki, till he had paid a large ranfom and married his daughter. The emperor Frederic, having got poffeffion of the ancient crown of Hungary, refufed to deliver it up, and Matthias found himfelf obliged to go to war for its recovery, which at length he procured by a treaty. He then marched into Bofnia, and recovered Jaycza, the capital, from the Turks, which fultan Mahomet afterwards vainly attempted to reconquer. In 1468, he made a truce with the Turks, and being at peace in his own dominions, he was induced, as well from motives of ambition, as by the perfuafions of the pope, to accept the crown of Bohemia offered him by the pontiff, on condition of extirpating the herefy of the Huffites in that country. Againft this harmlefs people, and his father-in-law, the king of Bohemia elect, he carried on a fanguinary war, which was terminated by a treaty, fecuring to him the crown after the death of Podzebrafki. Two years afterwards, that event took place, but the Bohemians elected Uladiflaus, fon of the king of Poland. Matthias, enraged at this proceeding, marched an army into the country, in order to compel the people to acknowledge him for their fovereign; he was however fhortly recalled by a rebellion in Hungary, led on by Cafimir, fecond fon of the king of Poland, to whom the crown had been offered. Matthias ftopped his progrefs, and, in his turn, became the aggreffor. War was continued till 1475, when, by a treaty, the king of Poland kept Lufatia, and the part of Silefia bordering on Bohemia, and Matthias retained the reft of Silefia and Moravia. While engaged in thefe contefts, the Turks were making great progrefs in the frontiers of Chriftendom: Matthias, as foon as he had leifure, turned his arms againft them, and having, in a meafure, attained his object, he attacked the emperor Frederic III., with whom he had a quarrel in 1478. After ravaging Auftria, and laying fiege to Vienna, he confented to withdraw his troops, on being paid the expences of the war, and receiving the inveftiture of Bohemia from the emperor, who was to renounce his title of king of Hungary. The payment being refufed, and the title ftill retained, Matthias invaded Lower Auftria, of which, together with Vienna, he made himfelf the complete mafter in 1487. He died in that city in 1490, about the fiftieth year of his age, leaving no iffue but a natural fon. Matthias was reckoned one of the moft fplendid monarchs of his age; a man of great enterprize, and of fine military talents, liberal and magnificent, an encourager of learning and the fine arts: he was himfelf acquainted with a variety of languages, and was lively and pleafant in converfation. He was, however, ambitious, and fo violent in his temper, as fometimes to furpafs, in his refentment, the boundaries of juftice and humanity, though he was at no time deftitute of the generofity and magnanimity that characterize a great prince. Univer. Hift.

Matthias, *St.*, in *Geography*, an ifland in the Eaft Indian fea, about 90 miles in circumference. St. lat. 1° 50'. E. long. 144° 30'.

MATTHIEU, Peter, in *Biography*, was born at Porentru, in France, of a family in humble life. He ftudied among the Jefuits, became principal of the college of Verceil, and was afterwards an advocate at Lyons. He attached himfelf to the ftudy of the belles lettres, but was particularly partial to hiftory, to which he chiefly devoted himfelf when he took up his refidence at Paris. He had an intention of, writing the hiftory of Alexander, prince of Parma, but was not permitted to ftay long enough in the country to accomplifh his defign. He was introduced to Henry IV. by the prefident Jeannin, and at the death of Du Haillon was made hiftoriographer of France. He was affiduous in collecting memoirs of every kind, relative to the times in which he lived, as well as the earlier periods of French hiftory. He was continued in his office by Lewis XIII., and accompanied that king in his wars againft the Hugonots. He died at Touloufe in 1621. His works are not reckoned among thofe of the firft rank, but they are efteemed exceedingly ufeful for elucidating the periods on which he treats: among thefe are the following; "L'Hiftoire des Chofes memorables arrivèes fous le Regne de Henri le Grand:" "Hiftoire de la Mort dèplorable de Henri le Grand:" "Hiftoire de St. Louis et Louis XI.;" "Hiftoire de France fous François I, Henri II., François II., Charles IX., Henri III. et IV, et Louis XIII." This laft was a pofthumous work, and publifhed by his fon, who continued the hiftory of Lewis XIII. to 1621. He was author of fome moral verfes, entitled "Quatrains fur la Vie et la Mort;" and the tragedy "La Guifade." Moreri.

MATTHIOLA, in *Botany*, is a genus of Plumier's, named by him after Peter Andrew Matthiolus, the moft popular commentator on Diofcorides; fee the following article. Linn. Gen. 566. Schreb. 131. Willd. Sp. Pl. v. 1. 998. Mart. Mill. Dict. v. 3. Juff. 206. Plum. Gen. 16. t. 6.—Clafs and order, *Pentandria Monogynia.* Nat. Ord. *Rubiaceæ*, Juff.

Gen. Ch. (according to Linnæus) *Cal.* Perianth cylindrical, entire, erect, fhort, permanent. *Cor.* of one petal, very long, its flender tube gradually terminating in an undivided limb, waved at the margin. *Stam.* Filaments five, awl-fhaped, fhorter than the corolla; anthers fimple *Pift.* Germen globofe, inferior; ftyle thread-fhaped, the length of the corolla; ftigma thickifh, blunt. *Peric.* Drupa globofe, of one cell, crowned with the calyx. *Seed.* Nut globofe, with a globofe kernel.

Eff. Ch. Corolla tubular, fuperior, undivided. Calyx entire. Drupa with a globofe nut.

1. M. *fcabra.* Rough Matthiola. Linn. Sp. Pl. 1661. (M. folio afpero fubrotundo, fructu nigricante; Plum. Ic. 166. t. 173. f. 2. Rategal, arbore indiano; Zann. Ift. 167. t. 75. f. 1, 2? Guettarda fcabra; Vent. Choix de Pl. 1. t. 1.)—Gathered by Plumier in the Weft Indies. Ventenat fays, it is a native of the Caribbee iflands.

This has always been a very obfcure plant. Plumier reprefents presents it as a *shrub*, with scattered, obovate, entire, very rough *leaves*, the *flowers* somewhat cymose, with pinnated *bracteas*. This last character however is erroneous, as well as the same author's figure and description of the *flower*, from whence Linnæus took his generic characters. Reichard and Swartz have long ago suspected the *Matthiola* to be a *Guettarda*, and Ventenat has at length reduced it to that genus, in the new work, left unfinished at his death, entitled *Choix de Plantes*. He saw the plant in flower in the gardens at Paris, and appears to have had no doubt of its being the same as Plumier's. See GUETTARDA; to the species of which this should now be added, by the name of

G. *scabra*. Leaves obovate, pointed, rough; rugged above; veiny beneath. Flowers with six stamens.—The *stem* is as thick as that of an apple-tree, with numerous, horizontal, widely spreading branches, whose subdivisions are opposite, round, rough, with short grey hairs, and leafy at the extremity. *Leaves* opposite (not scattered), on short thick stalks, accompanied by a pair of awl-shaped *stipulas*. They are three inches long and above an inch broad, rough like the foliage of a fig, obovate, or somewhat elliptical, slightly wavy; dark green above; downy and whitish beneath. *Flower-stalks* axillary, shorter than the leaves, divided at the top into two spreading dense spikes of white, silky, short-lived, highly scented *flowers*, much resembling a jasmine. The *bracteas* are lanceolate and crowded, so that Plumier's figure, though not very inaccurate, easily missed Linnæus. The limb of the *corolla* is divided into six oval horizontal segments, one-third the length of its tube. *Drupa* as big as a cherry, black and bitter, its nut of from four to six cells.—This seems to be what Lamarck has figured in his t. 154. f. 3. He, like Ventenat, has properly preferred the name *Guettarda*, to the more ancient one of *Matthiola*, because of the number of species already known under the former appellation, which it would be inconvenient to call *Matthiolæ*. So the old *Genipa* of Plumier is rightly sunk in the modern but better known *Gardenia*. The synonym of Zannoni, quoted by Linnæus with hesitation, ought surely to be excluded. See GUETTARDA and GARDENIA.

MATTHIOLUS, or MATTIOLI, PETER ANDREW, in *Biography*, an eminent physician, and medical botanist, was born at Sienna, in Tuscany, in the year 1501, where his father practised the same profession. His early education was received at Venice; and thence he was sent to the university of Padua, for the purpose of studying the law; for which, however, he conceived an antipathy, and turned his attention to medicine. His studies were prematurely interrupted by the death of his father; but his conduct had acquired for him the good opinion of the professors, who gave him the degree of doctor before his departure from the university. He returned to Sienna, where he speedily succeeded in finding ample employment. He appears, however, to have quitted his native place subsequently, and to have gone to Rome; whence he removed, in 1527, to the court of cardinal Bernardo Clesio, prince bishop of Trent, who held him in great estimation. He resided 14 years in the valley of Anania, in the district of Trent, where he acquired the respect and affection of the inhabitants to such a degree, that on his departure, men, women, and children accompanied him on his way, calling him their father and benefactor. He next settled as public physician at Gorizia, where a singular proof of the esteem in which he was held was likewise given; when a fire having consumed all his furniture, the people flocked to him the next day, with presents of goods and money, that made him richer than before, and the magistrates advanced him a year's salary. After a residence of twelve years at Gorizia, he accepted an invitation from Ferdinand, king of the Romans, to take the office of physician to his son, the archduke Ferdinand. He was greatly honoured at the imperial court, and in 1562 was created aulic-counsellor to the emperor Ferdinand. Afterwards Maximilian II. prevailed upon his brother to part with him, and made him his first physician. Finding, however, the weight of age pressing upon him, Matthiolus took leave of the court, and retired to a life of repose at Trent, where he soon after died of the plague, in the year 1577.

He left several works, of which the following are the titles: "Dialogus de Morbi Gallici curatione," printed in the collection of Luisinus. "Apologia versus Amatum Lusitanum," Venice, 1558. "Epistolarum Medicinalium, Libri V." Prague, 1561. "Disputatio adversus viginti Problemata Melchioris Guilandi," Ven. 1563. "Opuscula de Simplicium Medicamentorum Facultatibus secundum genera et loca," ibid. 1569; which is a compendium of vegetable materia medica. His Epistolæ also relate chiefly to the virtues of plants, and their mode of exhibition.

The great work, however, by which this physician acquired his fame and honour, was his commentary on the writings of Dioscorides. His first Commentaries in illustration of this ancient botanist, were printed at Venice in 1548, in the Italian language, with the title of "Il Dioscoride, con li suoi discorsi, aggiuntovi il sesto libro de gli antidoti contra tutti i veneni." It was soon twice reprinted. He afterwards published it in the Latin language, and with the addition of small cuts, in 1554, with the title of "Commentarii in sex Libros P. Dioscoridis, adjectis quamplurimis plantarum et animalium imaginibus." Numerous editions, in Latin, enlarged and improved, were afterwards given; and the work was also many times reprinted in Italian, and in French and German translations by different persons. The best edition is that of Venice, 1565, folio, with large plates. Haller remarks, when speaking of the value of this work, that while the author was deeply versed in the study of the Arabians and their followers, he too much neglected the original sources, and the examination of plants. He was, therefore, frequently imposed upon by his correspondents, and sometimes even gave fictitious representations of plants, drawn merely from the descriptions of the ancients. He did not, however, altogether neglect the examination of plants; for he discovered several in Bohemia, and the district about Gorizia, the medicinal properties of which he made the subject of experiments on malefactors. He certainly contributed much to lay the foundation of botanical science; but, as Eloy remarks, the multitude of editions and versions of his work evinces the penury of the age in botanical books. An edition of all his works was published by Caspar Bauhin, with the addition of more than three hundred figures, at Basle, in 1598, folio, which was reprinted in 1674.

Matthiolus was twice married, and left several children: one of his sons was physician to the elector of Saxony. Gen. Biog. Eloy. Haller. Bibl. Botan.

MATTIA, in *Geography*, a river of Albania, which runs into the Adriatic, S. of Alessio.

MATTIACI, in *Ancient Geography*, a people who, according to Tacitus, resembled the Batavi in their habits and manners, and who had a common origin with them. They were alike valiant, but less firm in combat. They were taken under the protection of the Romans, and are supposed to have inhabited the country now called Zealand.

MATTIACUM, a town of Germany, placed by Ptolemy between Budoris and Artaunum; fuppofed to be Marpurg in Heffe.

MATTIG, in *Geography*, a river of Bavaria, which runs into the Inn, near Braunau

MATTIGAY, a town of Hindooftan, in Myfore, on the Cavery, oppofite to Allumbaddy.

MATTIGKOFEN, a town of Bavaria; nine miles S. of Braunau.

MATTINATELLO, a town of Naples, in Capitanata; feven miles E. of Monte St. Angelo.

MATTINS, from the Italian, *mattina*, or the French, *matin*, *morning*, the firft part in the daily fervice of the Romifh church.

Mattins are fometimes held early in the morning, fometimes at midnight, and fometimes the evening before; and infirm people, even in monafteries, are difpenfed from attending mattins.

MATTKEM, in *Ornithology*, a common name in Germany for the *Matkneltzel*.

MATTO-GROSSO, in *Geography*. See MATO-GROSSO.

MATTS, on board a *Ship*, a kind of broad, thick clouts wove out of fpun-yarn, or of a variety of ftrands, or feparate parts of a fmall rope, or of a number of rope-yarns, twifted into foxes; and ufed to preferve the main and fore-yards from galling againft the mafts at the ties, and at the gunnel of the loof. They alfo ferve to keep the clew of the fail from galling there; as alfo to fave the clews of the fore-fail from doing fo at the beak-head and boltfprit. The longeft and ftrongeft fort of thefe matts are called panches.

MATT-SEE, in *Geography*, a lake in the archbifhopric of Salzburg; 12 miles in circumference.—Alfo, a town of the fame archbifhopric; a fief of the bifhop of Paffau; 12 miles N. of Salzburg.

MATTUSCHKÆA, in *Botany*, named by Schreber, in commemoration of count Mattufchka, a German botanift, who was born in the year 1734, and died in 1779. The following works rank him in the lift of authors on botany. In 1776, and the following year, Mattufchka publifhed his *Flora Silefiaca*, in 2 vols. 8vo.; and in 1779 appeared his *Enumeratio ftirpium in Silefia fponte crefcentium*, in 1 vol. 8vo., a fort of compendium of the other work.—Schreb. 788. Willd. Sp. Pl. v. 1. 606. Vahl. Symb. p. 3. 11. Mart. Mill. Dict. v. 3. (Perama; Aubl. Guian. 54. Juff. 109. Lamarck Illuftr. t. 68.)—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Vitices*, Juff.

Gen. Ch. *Cal.* Perianth inferior, cloven into four, ovate, acute, villofe fegments. *Cor.* of one petal; tube long; limb cloven into four roundifh lobes. *Stam.* Filaments four, nearly equal, the length of the clefts of the limb; anthers roundifh, two-celled. *Pift.* Germen fuperior, four-cleft, furrowed on each fide; ftyle thread-fhaped; ftigma fimple, (Aubl.) *Peric.* none. *Seeds* two or four, very fmall, naked (Juff.)

Eff. Ch. Calyx in four deep fegments. Corolla funnel-fhaped, equally four-cleft. Seeds naked.

1. M. *hirfuta*. Willd. n. 1. (Perama hirfuta; Aubl. Guian. t. 18.)—A native of moift and fandy places at Aroura and Orapu, in Guiana, where it flowers in June or July. According to Aublet, the whole plant is completely covered with reddifh or rufty hairs. *Stem* flender, branched, villofe, from one to two feet high. *Leaves* oppofite, feffile, ovate, villofe, longitudinally ribbed. *Flowers* capitate, terminal, yellow. *Receptacle* chaffy, with fringed fcales between each flower.—Vahl's defcription of this plant differs fomewhat from the former, for which reafon we fubjoin profeffor Martyn's tranflation. "*Stem* thread-fhaped, erect, frequently quite fimple; hirfute, as is the whole plant, efpecially the calyx. *Leaves* almoft like thofe of *Thymus ferpyllum*, feffile, oppofite, acute, veinlefs, obfcurely three-nerved; the loweft fmaller, approximating, ovate; the upper oblong, remote, three lines long. *Flowers* in a terminal feffile head, the fize of a pea. This plant is a finger's length in height, or more, but never fo gigantic as Aublet has drawn it, according to an obfervation of Van Rohr, an eye-witnefs, who gathered it in Guiana."

MATTUT, in *Geography*, a town of Perfia, in Chufiftan; 15 miles N.E. of El-Tiib.

MATTY'S ISLAND, an ifland in the Pacific ocean, difcovered by Capt. Carteret in 1767. S. lat. 1 45. E. long. 143° 2'.

MATUARO, an ifland near the N.E. coaft of New Zealand, on the S.E. fide of the Bay of Iflands. S. lat. 35°. E. long. 156 28'.

MATUGUAN, a town of Peru, in the audience of Lima; 60 miles N. of Guanca Velica.

MATVIEV, an ifland of Ruffia, in the ftraits of Vagatfkoi. N. lat. 69 15'. E. long. 52 14'.

MATVIEVKA, a town of Ruffia, in the government of Ekaterinoflav, on the Bug; 40 miles N.W. of Cherfon.

MATUITI, in *Ornithology*, a name given by Ray, Willughby, and Buffon, to the Brafilian fpotted king-fifher of Latham, or *Alcedo maculata*. See ALCEDO.

MATUITUI, a name given by Marcgrave to the fea-lark or ringed-plover. See CHARADRIUS *Hiaticula*. See alfo TANTALUS *Grifeus*.

MATULAM, *Hydrops ad Matulam*. See HYDROPS.

MATURA, in *Geography*, a fmall village and fort at the fouthernmoft point of Ceylon; 30 miles E. of Point de Galle. (See GALLE.) The country round Matura is very wild, but well fupplied with provifions of all forts, and particularly game, which is abundant. The houfe for the commandant is tolerably good, agreeably fituated near the river, which is broad here, and runs into the fea at a fmall diftance. The circumjacent country abounds with elephants, and here they were principally caught for exportation. Every three or four years the elephant is hunted here, by order of government. In 1797, at one of thefe hunts, 176 were caught, and this was the greateft number ever known to be taken at one time. Matura is four miles diftant from DONDRE *Head*; which fee.

MATURA, a chain of villages of Egypt, on the right bank of the Nile; 12 miles N. of Enfeneh.

MATURANTIA, in *Medicine*, &c. *ripeners*; or fuch things as promote maturation; are fuppofed to favour the production and complete formation of pus in inflammatory humours. There are, certainly, fays Dr. Cullen, means which may be employed for favouring thefe operations of nature; but as it cannot be admitted that any medicines are endowed with any fpecific powers to this purpofe, the term, as applied to medicine, feems to be quite improper. See SUPPURATION.

MATURAQUE, in *Ichthyology*, the name of an American fifh, of the harengiform kind, and having only one fhort fin on the back. It feldom grows to more than four inches long, and is fomewhat flattifh, but not very broad; its head is very broad, and covered with a fhelly cruft; it is caught in lakes, not in rivers, and is a well-tafted fifh.

MATURATION *of* FRUIT, in *Gardening*. See CAPRIFICATION, FORCING, and HOT-*Beds*.

MATURATION, in *Pharmacy*, a preparation of fruits, or other fimples, gathered before their maturity, to fit them to be eaten, or for other ufes. See FRUIT, &c.

MATURU,

MATURU, in *Geography*, a town of Brazil, on the river Xingi; 45 miles S.W. of Curupa.

MATUSARUM, in *Ancient Geography*, a town of Lusitania, S.E. of Scalabis. The Itinerary of Antonine marks it upon the route from Lisbon to Emerita.

MATUSFALVA, in *Geography*, a town of Hungary; 25 miles N.E. of Caschau.

MATY, MATTHEW, in *Biography*, a physician and man of letters, was the son of a refugee Protestant clergyman, from Beaufort in Provence, and was born at Montfort, near Utrecht, in 1718. He was originally intended for the clerical profession; but, in consequence of some mortifications which his father had received from the synod, on account of his sentiments relative to the Trinity, his attention was turned to the profession of medicine. He graduated at Leyden in 1740, and came to settle in England, his father having determined to quit Holland for ever. In 1747, he published at Leyden, "Essai sur le Caractère du Grand Medecin, ou Euloge critique de Boerhaave." Three years afterwards he began to publish at the Hague, in French, an account of the principal books printed in England, under the title of "Journal Britannique." This journal was well received, and answered the chief end which he had in view, by introducing him to the notice of some of the most respectable literary characters of the country, which he had adopted as his residence, and to whose active and uninterrupted friendship he owed the places which he afterwards obtained. At the institution of the British Museum in 1753, he was appointed an under-librarian; and at the death of Dr. Knight, in 1772, he became principal librarian to that establishment. In 1758 he was elected a fellow of the Royal Society; and in 1765, on the resignation of Dr. Birch, who soon afterwards died, and made him his executor, he was chosen secretary to that learned body. He filled these offices with great reputation, and was in general esteem for the benevolence of his private character, and the extent of his literary information. He died in 1776. In his medical capacity, Dr. Maty was distinguished as an active and zealous promoter of the practice of inoculating the small-pox; and actually re-inoculated himself, unknown to his family, in order to disprove the supposition that it might be produced a second time in this way. He translated, in 1768, Dr. Gatti's "New Observations on Inoculation," which had been originally written by the author at his request. He had nearly completed, at the time of his death, the "Memoirs of the Earl of Chesterfield," which were finished by his son-in-law, Mr. Justamond, and prefixed to an edition of the "Miscellaneous Works" of that nobleman, in 1777. Gen. Biog. Hutchinson's Biog. Med. Anecdotes of Bowyer.

MATY, PAUL-HENRY, son of the preceding, was born in 1745. He was educated at Westminster-school, whence, in 1763, he was elected to Trinity college, Cambridge, and obtained from thence a travelling fellowship. He passed three years on the continent, after which he was appointed chaplain to lord Stormont, ambassador at the court of France. He might, from his connections, have secured preferment in the church, but scruples concerning its doctrines and ceremonies prevented him from continuing to perform the duties of a minister in it. After his father's death he retired from its service, and, in 1777, he published his reasons for this step. From this period he devoted himself to a literary life, and was almost immediately appointed assistant librarian to the British Museum; he was elected one of the under librarians, and likewise succeeded Dr. Horsley as one of the secretaries of the Royal Society. In 1782 he commenced a review of select works, English and foreign, which he carried on almost without any assistance till 1786. He died, in the following year, at the age of forty-two. Mr. Maty published a translation of Riesbeck's travels through Germany, and translated into the French language the descriptions in the "Gemmæ Marlburienses." After his death a volume of sermons was published for the benefit of his family: they are spirited and original compositions; but the editor, through some inadvertence, printed, as Mr. Maty's, three that had been copied from the sermons of archbishop Secker. Gen. Biog.

MATYLUS, in *Ancient Geography*, a town of Pamphylia, placed by Ptolemy between the mouth of the river Cataractus and that of the river Caster.

MATZEN, in *Geography*, a town of Austria; seven miles S. of Zisterstorff.

MATZENDORF, a town of Switzerland, in the canton of Soleure; six miles N. of Soleure.

MATZOL, a cape of Russia, at the mouth of the Obskaia gulf. N. lat. 72° 30'. E. long. 75° 30'.

MATZUNEA, a town of Poland, in the palatinate of Kiev; 24 miles S.W. of Kiev.

MAU, a town of the island of Ceylon; 40 miles W.N.W. of Candi.

MAVA, a river of Africa, which passes through the country of Quoja, and runs into the Atlantic near cape Monte.

MAUBAL, a town of Candahar; 65 miles N.N.E. of Candahar.

MAUBECHE, in *Ornithology*, a name given by Buffon to the TRINGA *Calidris*; which see.

MAUBEUGE, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Avesnes, situated on the Sambre. The place contains 4726, and the canton 14,084 inhabitants, on a territory of 205 kiliometres, in 32 communes. N. lat. 50° 16'. E. long. 4° 2'.

MAUBOURGUET, a town of France, in the department of the Upper Pyrenées, and chief place of a canton, in the district of Tarbes; 15 miles N. of Tarbes. The place contains 1400, and the canton 7345 inhabitants, on a territory of $102\frac{1}{2}$ kiliometres, in 11 communes.

MAUCAUCO, in *Zoology*. See LEMUR and VIVERRA *Caudivolvula*.

MAUDERDALLY, in *Geography*, a town of Hindoostan, in Coimbetore; 10 miles W.N.W. of Coimbetore.

MAUDIHOCA, the cassada, or the poisonous root of which bread is made in many parts of the West Indies.

MAUDISIMILIA, in *Geography*, a town of Hindoostan, in Bahar; 35 miles S.E. of Bahar.

MAUDLIN, in *Botany*. See YARROW, and AGERATUM.

MAUDUIT, JAQUES, in *Biography*, said by M. Laborde to have been a great musician in the time of Henry IV. who accompanied wonderfully on the lute. (Essais sur la Mus. t. iii. p. 519.) We are likewise told, that he added a sixth string to viols, which had originally but five; and that he was the first in France who introduced these instruments in concert, instead of base-viols.

Père Mersenne, who had a particular regard for this musician, has given us an engraved head and eloge of him in his "Harmonie Universelle;" with the chief part of which we shall present our readers.

"Jaques Mauduit, descended from a noble family, was born in 1557. He had a liberal education, and travelled during his youth into Italy, where he learned the language of that country, together with Spanish and German, which, with the literature he had acquired at college, enabled him to read the best authors of almost every ki[nd]. He had a general knowledge of most sciences as well a[s] mechanics; and studying music with unwearied diligen[ce] without any other assistance than that of books, he rendered himself so eminent, that he was honoured, even during [h]is life, with the respectable title of *Père de la Musique*," f[athe]r of music. "And with reason," says his panegyrist, "be[ing] the inventor of good music in France, by the many ex[ce]llent works he published, both vocal and instrumental, wh[ich] have been long the ornament of our concerts.

"His merit obtained him admission into the [fa]mous Academy of Music, instituted by the learned B[aïf], 1583; and many writers of his time seem to have produ[ced] their poetical effusions, in order to have them immortali[ze]d by the airs of Mauduit.

"The first composition in which he distinguished himself as a learned harmonist, was his mass of Req[uie]m, which he set for the funeral of his friend, the celebra[ted] poet Ronsard; it was afterwards performed at [th]e funeral of Henry IV. and, lastly, at his own, 1627, under the direction of his son Louis Mauduit, at which [o]ne Mersennus officiated in the sacred function as priest.

"He left behind him innumerable masses, [h]ymns, motets, fancies, and songs. A small hereditary pla[ce] at the court of requests descended to him from his fa[th]er, which he seemed to exercise for no other purpose th[an] to oblige and serve his friends. At the siege of Paris, [wh]en the Fauxbourg was taken by storm, he ventured thro[ug]h the victorious soldiers to the house of his friend Baïf, [t]hen dead, and saved all his manuscripts, at the hazard of h[is] own life.

"Upon a similar occasion, in which there [w]as still greater difficulty and danger, he saved the *douze mod[es]* de Claude le Jeune, and his other manuscript works, at th[e] time that this composer was seized at the gate of St. D[en]is as a Hugonot; so that all those who have since receive[d] pleasure from the productions of this excellent master, [a]re obliged to Mauduit for their preservation, as he saved the[m] from destruction by seizing the arm of a serjeant at the [ve]ry instant that he was going to throw them into the flames; [p]ersuading the soldiery that these papers were perfectly inn[o]cent and free from Calvinistical poison, or any kind of trea[so]n against the League: and it was by his zeal and address, [w]ith the assistance of an officer of his acquaintance, that C[l]aude escaped with his own life."

Such are the praises bestowed upon Jaques Mauduit, by his friend the learned and benign Mersennus, w[ho]se diligence, science, and candour, far surpassed his taste. The Requiem, by Mauduit, is printed in the Harm. Univ. in five separate parts; but in scoring it, neither the harmony nor modulation offer any thing that is either curious or uncommon, at any period of counterpoint. It is in literally *plain* counterpoint of crotchets and minims moving all together, as in our cathedral chanting. The chief merit of this production is in the exact accentuation of the words, *à l'antique*: a minim for a long syllable, and a crotchet for a short.

Mersennus, in his Commentary on Genesis, has illustrated his musical remarks with many of his friend Mauduit's compositions, in which we have never been able to dig out the least fragment that would do honour to this composer or his country.

MAVEBARA, in *Geography*, a town of South America, in the province of Choco; 20 miles N. of Zitara.

MAVELAGONGUE, a river of Ceylon, which runs into the sea at Trinconomaly.

MAVELICAN, a town of Hindoostan, in the Carnatic; 40 miles from Travancore.

MAVENHELLY, a town of Hindoostan, in the Mysore, ceded to Great Britain in 1799; 60 miles S.E. of Seringapatam.

MAUG, Tuhas, or *St. Laurence*, one of the smalle[st] of the islands called "Ladrones," composed of three rocks, about 20 miles in circumference; 15 miles from the island of Assumption.

MAUGERVILLE, a township of Sunbury county, in the province of New Brunswick, in St. John's river, 30 miles above Belisle. N. lat. 45° 59'. W. long. 66° 40'.

MAUGHOLD Head, a cape on the E. coast of the Isle of Man; 40 miles W.S.W. from St. Bee's Head. N. lat. 54° 18'. W. long. 3° 28'.

MAUGSEE, three small islands in the East Indian sea, between Borneo and Paraguay. N. lat. 7° 33'. E. long. 117° 30'.

MAUGUIO, a town of France, in the department of the Herault, and chief place of a canton, in the district of Montpellier; six miles E. of Montpellier. The place contains 1167, and the canton 3386 inhabitants, on a territory of 160 kiliometres, in five communes.

MAUHLIA, in *Botany*. Dahl. Obs. Bot. 25. Thunb. Prod. 60, is the same genus with the *Agapanthus* of Solander in Ait. Hort. Kew. ed. 1. v. 1. 414, the *Tulbaghia* of Heister; see Agapanthus. The only genuine species is *Agapanthus umbellatus*, Curt. Mag. t. 500. Redout. Liliac. t. 6. (Crinum africanum; Linn. Sp. Pl. 419.) Thunberg however has added a second, by the name of *Mauhlia ensifolia*, and he is followed by Willdenow; but their plant is our *Massonia ensifolia*. See Massonia.

The name of *Mauhlia* was given by Dahl, (see Dahlia,) in honour of Mr. John Mauhle, who, as this author informs us, had for many years the superintendance of the Swedish mercantile affairs in China; and has, since his return, laboured, with great ardour, to promote various economical objects at home. He is said to have furnished Dahl with the sum necessary for the purchase of the Linnæan Museum; (see Linnæus the son,) in order that it might not go out of Sweden; and the narrator above-mentioned asserts that "the same sum of money for which it passed into foreign hands, was offered to retain it." This assertion bears hard upon the honour and patriotism of the highly respectable professor Acrel, who alone was entrusted with the sale of the collection in question, and we have his authority to say the account is incorrect. We know also that this excellent man was falsely accused of having received a bribe from the actual purchaser, because he behaved honourably and impartially in his trust; and we know moreover that he did reject with indignation an offer, from another quarter, to betray it. He had even to resist the dishonest cupidity of the heirs of the younger Linnæus, who, on receiving unlimited offers from the empress of Russia, would have left in the lurch the person with whom they were in treaty, and who did not hesitate to purchase the whole at their own price, and in their own way. S.

MAVILE, in *Geography*, a town of Hindoostan, in the circar of Cicacole; 27 miles S.W. of Cossimcotta.

MAVIS, in *Ornithology*, the common name of the song-thrush, or throstle. See Turdus *musicus*.

MAUKS, in *Agriculture*, a provincial word applied to maggots.

MAUL, in *Rural Economy*, a provincial term signifying a beetle, mallet, &c.

MAULDAH, in *Geography*, a circar of Bengal, of a triangular form, and about 45 miles in circumference; situated between Rajemal and Dinagepour.—Also, the capital of of the said circar, which is a place of considerable trade; 52 miles N. of Moorshedabad. N. lat. 25° 3'. E. long. 88° 16'.

MAULE, a river of Chili, which runs into the Pacific ocean, S. lat. 35° 12'.

MAULEN, a town of Prussia, in the province of Natangen; seven miles S.W. of Konigsberg.

MAULEON, a town of France, and chief place of a district, in the department of the Lower Pyrenées, having a castle on a rock, formerly deemed impregnable; 12 miles W. of Oleron. The place contains 1010, and the canton 12,497 inhabitants, on a territory of $317\frac{1}{2}$ kiliometres, in 28 communes. N. lat. 43° 13'. W. long. 0° 49'.

MAULEON-*en-Barousse*, a town of France, in the department of the Upper Pyrenées, and chief place of a canton, in the district of Bagnères; nine miles S.E. of La Barthe. The place contains 612, and the canton 6495 inhabitants, on a territory of 185 kiliometres, in 25 communes.

MAULI, a river of Sicily, which runs into the sea, about eight miles S.S.W. from Ragusa. N. lat. 36° 40'. E. long. 13° 45'.

MAULIAVERAM, or SEVEN PAGODAS, a town of Hindoostan, in the Carnatic, situated on the coast; 30 miles S. of Madras.

MAULPOUR, a town of Hindoostan, in Lahore; 10 miles N. of Rahoon.

MAULSURDA, a town of Bengal; 55 miles S.S.W. of Doesa.

MAUM, in *Agriculture*, a term provincially signifying a certain dry mellow quality in land. A sort of dry fine loam.

MAUMUSSON, in *Geography*, a channel or narrow sea between the isle of Oleron and the continent of France.

MAUNCH, in *Heraldry*, the figure of an ancient sleeve of a coat, which is borne in many gentlemen's escutcheons; as in the earl of Huntingdon's.

MAUNCORE, in *Geography*, a town of Bengal; 20 miles N W. of Burdwan.

MAUND, in our *Old Writers*, a kind of great basket or hamper, containing eight bales, or two fats; it is commonly a quantity of eight bales, of unbound books, each bale having one thousand pounds weight.

MAUND, in *Commerce*, the denomination of a weight in the East Indies. In Bengal heavy goods are weighed by the maund of 40 seers, each seer being divided into 16 chittacks. The maund of the English factory in Bengal weighs 74lb. 10 oz. $10\frac{2}{3}$dr. avoirdupois; so that the seer is 1lb. 13 oz. $13\frac{7}{8}$dr. and the chittack 1oz. $13\frac{3}{8}$dr. The Bengal Bazar maund is 10 *per cent.* heavier than the maund of the factory, and therefore weighs 82lb. 2oz. $2\frac{2}{11}$dr. avoirdupois; and in this case, the seer is 2lb. 0 oz. $13\frac{3}{5}$dr., and the chittack, 2oz. $0\frac{5}{8}$dr. Grain is sold by the Khahoon of 16 soallee, which is equal to 40 maunds. Liquids are sold by the chatack of 5 sicca weight; 16 chatacks making 1 pouah, 4 pouah 1 seer, and 40 seers 1 maund. At Madras goods are sold by the candy of 20 maunds, and the maund is divided into 8 vis, 320 pollams, or 3200 pagodas. The candy of Madras is 500lb. avoirdupois. In the Jaghire, or territory belonging to the English company round Madras, and in most other parts of the Coromandel coast, the Malabar weights are used, and are as follow: the gursay, called by the English garce, contains 20 baruays or candies; the baruay, 20 manungus or maunds; the maund 8 visay or vis, 320 pollams, or 3200 varahuns; each varahun weighing $52\frac{3}{4}$ English grains; so that the visay is 3lb. 3dr., the maund, 24lb. 2oz., the baruay, $482\frac{1}{4}$lb., and the gursay $9645\frac{1}{2}$lb. avoirdupois, 4 tons 6cwt. nearly. In corn measure, the garce is = $\frac{1}{2}$ English quarters nearly. When grain is sold by weight, $16\frac{1}{2}$lb. are reckoned for 1 garce, being 18 candies $12\frac{1}{2}$ mds. At Bombay the commercial weight is the candy 20 maunds, the maund being subdivided into 40 seers, anhe seer into 30 pice. The candy is 560lb., the maund 2., and the seer $11\frac{1}{5}$oz. avoirdupois. Goods are likewise ld by the Surat maund, and the Pucca or Bengal mau, so that, in every contract, the particular maund, or dy, should be mentioned. A bag of rice weighs 6 mnds, or 168lb. avoirdupois, and a candy is equal to 25 'nchester bushels nearly. At Calicut, on the Malabar coa the candy weight contains 20 maunds, and the maund 1 pools or paloons. The maund used here by the English ighs 30lb., and the candy, 600lb. But the common weigs are those of Malabar, the maund weighing 24lb. 2oz., a the candy $482\frac{1}{2}$lb. avoirdupois. At Carwar, on the Malab coast, the maund is 26lb. avoirdupois, and is divided into seers or 1000 pice, and the candy is 20 maunds. At Cochin the maund is 27lb. $2\frac{4}{5}$oz. avoirdupois, and the candy = 20 maunds = 543lb. 8 oz. avoirdupois. At Goa the und contains 24 rattles, = $24\frac{3}{4}$lb. avoirdupois, so that t candy of 20 maunds is equal to 495lb. avoirdupois. Cornnd rice are sold by the candy of 20 maunds, which are equ to 14 English bushels nearly. At Mangalore, the manor maund, by which goods are sold in the market, contas 46 seers, or 28lb. $2\frac{1}{4}$oz. avoirdupois: the maund, by wh the merchants buy and sell, weighs 16 rupees more, th is 28lb. $4\frac{1}{2}$oz. avoirdupois; the baru or candy is 20 maids. At Masulipatam the candy is 20 maunds, the maund 8 v, 40 seers, 600 neves, or 900 dabous. This maund weighs $4\frac{1}{2}$lb. avoirdupois nearly. At Pondicherry the commerci weight is the candy of 20 maunds, or 160 vis. The mad is = 24lb. French poids de marc, or 25lb. 14oz. $5\frac{1}{2}$r. avoirdupois. At Scindy heavy goods are weighed by t maund of 40 seers. The cutcha or Surat maund is = 7lb. 5oz. $5\frac{1}{3}$dr. avoirdupois, and is divided into 16 annas, or 32 pice; the Pucca maund is double the former. At Surat, the maund for weighing heavy goods is 40 seers, and the seer 30 pice: 20 Surat maunds, or 10 Pucca or Bengal factory maunds make 1 candy, or 746lb. 10oz. 10dr. avoirdupis. But these weights vary. At Tranquebar the maund weighs 68lb. Danish, or $74\frac{4}{5}$lb. avoirdupois. At Acheen, in the isle of Sumatra, a maund of 75lb. of rice contains 21 banboes, a bamboe being 4 and sometimes 5 cauls. Kelly's Cambist. vol. i.

MAUNEA, in *Geography*, a town of Bengal; 30 miles N.W. of Nattore.

MAUNEAR, a town of Bengal; 10 miles W. of Midnapour.

MAUNDY, or MAUNDEY *Thursday*, *Dies Mandati*, the Thursday before Easter; so called from the French *mande*, i. e. *portula*; it being a custom on that day to give a largess or bounty to certain poor men, whose feet the king formerly washed, as a mark of humility, and in obedience to the command of Christ.

MAUNDYGAUT, in *Geography*, a town of Hindoostan, in the soubah of Delhi; 27 miles E.N.E. of Secundara.

MAUNSEE, a town of Austria, near a lake of the same name; 16 miles S.W. of Voglabruck.

MAUNSI, a river of Bengal, which falls into the Toorsha, and after their confluence they assume the name of Neelcoomer, and shaping their course through Baharbund, fall with their united streams into the Berhampooter.

MAUNTRY,

MAUNTRY, a town of Hindoostan, in Mohurbunge; 12 miles S. of Harriorpour.

MAUPERTUIS, Peter-Lewis Moreau de, in *Biography*, a celebrated French mathematician and philosopher, who flourished in the eighteenth century, was born at St. Malo in the year 1698. He was privately educated till he was sixteen years of age, when he was sent to the college of La Marche, at Paris. He shortly discovered a strong inclination to mathematical pursuits, and a considerable taste for instrumental music, which he practised with success. At the age of twenty he determined on a military life, and entered among the mousquetaires, but after remaining two years in that corps, he obtained a company in a regiment of cavalry, which he held about three years. During this time he devoted all his leisure hours to scientific studies, and at length he quitted the profession of arms, and applied his mind entirely to mathematics. In 1723 he was received into the Royal Academy of Sciences, on which occasion he read his first performance, which was "A Memoir upon the Construction and Form of musical Instruments." He now paid a good deal of attention to natural philosophy, and discovered great knowledge and dexterity in observations and experiments upon animals. In 1728 he, with all the zeal of a devotee, visited the country which had given birth to Newton, of whose principles he became a zealous admirer and follower; and during his residence in London he was honoured with an admission into the Royal Society. Upon his return to France, he made an excursion to Basil, where he formed a friendship with the celebrated Bernouillis. On his return to Paris from Switzerland, he applied to his favourite studies with redoubled ardour, and enriched the transactions of the academy with a vast number of his communications, between the years 1724 and 1744. In some of these the most sublime and intricate questions in the mathematical sciences are discussed with precision, clearness, and elegance. In 1736, he was sent by Lewis XV., at the head of the French mathematicians, into Lapland, for the purpose of measuring a degree of the meridian within the polar circle, in order to determine the figure of the earth. The reputation which he acquired by this undertaking was so great, that he was admitted a member of almost every academy in Europe. In 1740 he was invited by the king of Prussia to go to Berlin, to be the president and director of the Royal Academy of Sciences and Belles Lettres in that place, which he readily accepted. When he arrived, the king was at war with the emperor, and our philosopher, whose love for his first profession of arms was not entirely effaced, determined to follow the king to the field. He was present at the battle of Molwitz; but before victory declared itself for the Prussians, his horse ran away with him into the enemy's ranks, where he was taken prisoner, and very roughly used. Being carried to Vienna, he there met with the most honourable reception from the emperor. This noble-minded prince, hearing him regret the loss of a watch by Graham, the celebrated English artist, which had been of great use to him in his experiments and astronomical observations, having another by the same maker, but enriched with diamonds, presented it to him, saying, "The hussars were only in jest with you, they have sent me your watch, and I gladly restore it to you." Notwithstanding his talents as a philosopher and mathematician, he was capable of paying well turned compliments to persons of the highest rank in life: in the course of conversation with the empress-queen, her majesty observed to him that she had heard the princess Louisa-Ulrica of Prussia was the most beautiful princess in the world. "Till this moment, madam," replied Maupertuis, "I was entirely of that opinion." He was soon afterwards allowed to depart for Berlin, loaded with favours by the emperor and empress. From thence Maupertuis went to Paris, and in 1742 was chosen director of the Academy of Sciences: during the following year he was received into the French Academy, and was the first instance of a person's being member of both the academies of Paris at the same time. After this he again assumed the character of a soldier, and was present at the siege of Fribourg, and, upon the surrender of that citadel, was appointed to carry the news of the event to the French king. In 1744 he returned to Berlin, and married a lady of great beauty and merit, to whom he was extremely attached, and his alliance with whom he considered as the most fortunate event of his life. In 1746, the king of Prussia declared our philosopher president of the Royal Academy of Sciences at Berlin, and soon afterwards honoured him with the order of Merit; and farther distinguished him with his own most intimate confidence. These accumulated honours served to stimulate him in his application to scientific researches, not only in mathematics, but in metaphysics, chemistry, botany, and polite literature. His temper was not good, and he was frequently involved in disputes with persons of distinguished talents: one of these was with Koenig, professor of philosophy at Franeker, in which Voltaire took a decided part against him. Maupertuis threatened to take on him personal revenge, to which Voltaire replied by reiterating the strokes of the most ludicrous satire. The constitution of the philosopher had been long impaired by fatigues of various kinds, and particularly by the hardships which he had undergone in his Lapland expedition; but the vigour of his mind was unabated, even at a time when, from severe illness, he was incapable of taking the chair of the academy. He died in 1759, when he was about the age of sixty-one. He was author of many works, of which the following may be noticed; "An Essay on Cosmology:" "A Discourse on the different Figures of the Stars:" "Philosophical Reflections upon the Origin of Languages, and the Signification of Words:" "An Account of the Expedition to the Polar Circle, for determining the Figure of the Earth, or, the Measure of the Earth at the Polar Circle:" "Observations on the Comet of 1742:" "The Measure of a Degree of the Meridian at the Polar Circle."

MAUPHAZE-Bunder, in *Geography*, a town of Hindoostan, in the circar of Cicacole; 4 miles S.E. of Cicacole.

MAUPIN, La, in *Biography*, one of the early and most extraordinary female singers in the operas of Lulli. M. Laborde has assigned, in his "Essais sur la Mus.," a piquant article to most of the favourite performers in these splendid musical dramas, with which Louis XIV. and the whole French nation were so delighted and so proud. Almost every individual of this syren troop is marked by some singularity of character, or peculiar circumstances; but none more so than La Maupin, the successor of La Rochois. She was equally fond of both sexes: fought and loved like a man, and resisted and fell like a woman. Her adventures are of a very romantic kind. Married to a young husband, who was soon obliged to absent himself from her, to enter on an office he had obtained in Provence, she ran away with a fencing-master, of whom she learned the small-sword, and became an excellent fencer, which was afterwards a useful qualification to her on several occasions. The lovers first retreated from persecutiou to Marseilles; but necessity soon obliged them to solicit employment there, at the opera; and, as both had by nature good voices, they were received without difficulty. But soon after this she was seized with a passion for a young person of her own sex, whom she seduced;

duced; but the object of her whimsical affection, being pursued by her friends and taken, was thrown into a convent at Avignon, where the Maupin soon followed her; and having presented herself as a novice, obtained admission. Some time after, she set fire to the convent, and, availing herself of the confusion she had occasioned, carried off her favourite. But being pursued and taken, she was condemned to the flames for contumacy; a sentence, however, which was not executed, as the young Marseillaise was found, and restored to her friends.

She then went to Paris, and made her first appearance on the opera stage in 1695, when she performed the part of Pallas, in "Cadmus," with the greatest success. The applause was so violent, that she was obliged, in her car, to take off her casque to salute and thank the public, which redoubled their marks of approbation. From that time her success was uninterrupted. Dumeni, the singer, having affronted her, she put on men's clothes, watched for him in the Place des Victoires, and insisted on his drawing his sword and fighting her; which he refusing, she caned him, and took from him his watch and snuff-box. Next day Dumeni having boasted at the opera-house, that he had defended himself against three men who attempted to rob him, she related the whole story, and produced his watch and snuff-box in proof of her having caned him for his cowardice. Thevenard was nearly treated in the same manner, and had no other way of escaping her chastisement than by publicly asking her pardon, after hiding himself at the Palais Royal during three weeks. At a ball given by Monsieur, the brother of Louis XIV., she again put on men's clothes, and having behaved impertinently to a lady, three of her friends, supposing the Maupin to be a man, called her out. She might easily have avoided the combat by discovering her sex, but she instantly drew, and killed them all three. Afterwards, returning very coolly to the ball, she told the story to Monsieur, who obtained her pardon. After other adventures, she went to Brussels, and there became the mistress of the elector of Bavaria. This prince quitting her for the countess of Arcos, sent her by the count, husband of that lady, a purse of 40,000 livres, with an order to quit Brussels. This extraordinary heroine threw the purse at the count's head, telling him, it was a recompence worthy of such a scoundrel and —— as himself. After this she returned to the opera stage, which she quitted in 1705. Being at length seized with a fit of devotion, she recalled her husband, who had remained in Provence, and passed with him the last years of her life in a very pious manner, dying in 1707, at the age of thirty-four.

MAUR, in *Geography*, a town of Austria; 7 miles S. of Mauttern.

MAUR, *St.*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Chinon; 15 miles S.E. of Chinon. The place contains 2271, and the canton 8357 inhabitants, on a territory of 185 kiliometres, in 12 communes.—Also, a town of France, in the department of Paris; 6 miles S.E. of Paris.

MAUR, *St.*, *Congregation of*, in *Ecclesiastical History*, a famous society of Benedictines, which was founded in the year 1620, by the express order of Gregory XV., and enriched by Urban VIII. in 1627, with several donations and privileges. This society has been distinguished by the great number of excellent rules and institutions that are observed in it, and by the regular lives and learned labours of its members. Those who have any acquaintance with the history and progress of learning in Europe, well know what signal advantages the republic of letters has derived from the establishment of this famous congregation, whose numerous and admirable productions have cast a great light upon all the various branches of philology and belles lettres, and whose researches have taken in the whole circle of sciences, philosophy excepted. These Benedictines still maintain their literary fame, by the frequent publication of laborious and learned productions in all the various branches of sacred and profane literature.

MAURACONDA, in *Geography*, a town of Africa, in the kingdom of Bursali. N. lat. 13° 40'. W. long. 15° 25'.

MAURANDIA, in *Botany*, received its name from Dr. Ortega, the professor of botany at Madrid, in honour of the lady of Dr. Maurandy, the botanical professor at Carthagena, said to be an ardent admirer and prosecutor of the same study with her husband. Cavanilles had given the generic appellation of *Usteria* to this plant, not being aware of its having been previously bestowed on another genus by Willdenow; for which reason, joined to that of complimenting the above named lady on her botanical acquirements, Ortega was induced to change it to *Maurandya*. In the Botanical Magazine we perceive that Dr. Sims, though he has adopted the genus, is not perfectly satisfied with it, or rather that "he cannot cordially coincide with Dr. Ortega, in the propriety either of his generic or trivial name." We content ourselves with reforming his orthography. Orteg. Hort. Matrit. dec. 2. 21. Jacq. Hort. Schoenb. v. 3. 20. Willd. Sp. Pl. v. 3. 389. (Usteria; Cavan. Ic. v. 2. 15.)—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Bignoniæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, cloven nearly to the base into five linear-lanceolate, acute, erect, almost equal segments. *Cor.* of one petal, two-lipped; tube shorter than the calyx; throat twice as long as the calyx, rather depressed, broad, with various furrows on each side, somewhat incurved; limb ringent, in five nearly equal, roundish, emarginate segments, two above and three below. *Stam.* Filaments four, thickened and hairy at the base, not so long as the throat of the corolla, two of them shorter; anthers oblong. *Pist.* Germen superior, ovate, with a furrow on each side; style awl-shaped, the length of the stamens; stigma simple. *Peric.* Capsule as long as the calyx, of two cells, each opening at the top with five, half-ovate, acute, reflexed valves. *Seeds* numerous, rather ovate, rough, affixed to each side of the partition.

Ess. Ch. Calyx inferior, in five deep segments. Corolla ringent; tube bell-shaped, furrowed. Capsule of two cells, opening by five teeth at their summit.

1. M. *semperflorens*. Climbing Maurandia, or Bastard Foxglove. Sims in Bot. Mag. t. 460. Jacq. Hort. Schoenb. t. 288. Usteria scandens; Cavan. Ic. t. 116. Andr. Bot. Repos. t. 63.

This, the only species known, is a native of Mexico, and an elegant greenhouse plant, flowering for months together in the summer. *Root* perennial, branched, sending forth numerous, annual, climbing, round, darkish, branched *stems*, about the thickness of a quill. *Branches* green, about three feet long, somewhat divided. *Leaves* alternate, on long twining footstalks, very numerous, spear-shaped, three, five, or seven-nerved. *Flowers* solitary, drooping, on long, twisted, axillary stalks, of a beautiful lilac, or purple and white, colour. They have great affinity to those of the Foxglove. *Seeds* oblong and black.

This truly elegant climber, which is beautifully figured in the works above quoted, from being easily propagated by cuttings as well as seeds, seems in a fair way of becoming common in our greenhouses, though said to be rather better suited to the conservatory.

MAURBACH, in *Geography*, a town and chartreux of Austria; nine miles W.N.W. of Vienna.

MAURE, *Mademoiselle* Catherine-Nicole le, in *Biography*, one of the last favourite singers in the French serious opera of the old school. She was born at Paris in 1704, and, according to M. Laborde, gifted with the finest voice that nature ever bestowed on a mortal. She was admitted, in 1719, only as a chorus-singer, and remained in that humble station till 1724, when she appeared in the character of Cephile, in the first part of "L'Europe Galante."

From that moment she never ceased to delight the audience, even to extacy, in every part that was assigned her. Her beautiful voice, manner of singing, and embellishments, were equally captivating. Mademoiselle le Maure, diminutive in figure, and ill made, moved on the stage with incredible dignity; she penetrated every heart so much by what she had to utter, that she drew tears from hearers the most frigid; she animated and transported them; and though she had neither beauty nor wit, she excited the most lively sensations.

She quitted the stage and returned to it several times, till 1743, after which period she never performed in public, except in the festivals given in celebration of the dauphin's first marriage, in 1745.

Her retreat was rather occasioned by caprice than fading talents; she might have remained on the stage ten years longer with her usual eclat. For after her retirement we have very frequently been present (continues M. Laborde) when she has sung and acted whole operas without appearing fatigued. The undertakers of the Colisée prevailed upon her to sing two or three times in 1771, and there never was so great a crowd assembled at a public place as she attracted to hear her. Mademoiselle le Maure continued to the end of her life superior to what might be expected from her age.

No one could dispute the perfection of her voice; and even young people, though a great change was begun in our music, found the charms of her vocal organs irresistible.

It would be an interesting inquiry to investigate the cause of that exquisite pleasure which the mere tone of a fine voice excites, without the concurrence of any reasoning faculty. Mademoiselle le Maure had no imposing figure, was neither pretty, nor gifted with superior intellects or reflections, without taste or education; yet, denied all these advantages, she had only to open her mouth, and breathe two or three sounds, to produce every effect resulting, with great difficulty, from the union of all the advantages of which she was in want. To what are we to ascribe this prodigy? It is one of those mysteries of nature which philosophy has not yet unfolded.

Mademoiselle le Maure, in 1762, was married to M. de Monbruelle; but she still remained best known, after her marriage, by her maiden name; so true it is that our place in society is determined by talents and useful faculties.

Maure, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Rédon; 15 miles N. of Rédon. The place contains 4110, and the canton 8370 inhabitants, on a territory of 205 kiliometres, in nine communes.

Maure, *St.*, or *Leucadia*, an island in the Mediterranean sea, about 50 miles in circumference, formerly joined to the continent, but now separated from it. (See Leucadia.) This island produces great plenty of game, wine, oil, citrons, pomegranates, almonds, and other fruits, with fine pastures. Its inhabitants are Greeks, subject to a bishop. It had formerly three considerable towns, with a very magnificent temple of Venus. The town which gives name to the island, contains about 6000 inhabitants; as it is situated in the water, and defended by walls and towers, it is not easy of access either by land or water. Beyond its works, in a morass, are two well inhabited islands, or suburbs; and the little islands between this and the continent communicate by bridges. It has repeatedly changed master, being sometimes under the dominion of the Turks, and sometimes under that of the Venetians. By the treaty of Campo Formio it was ceded to France; but in 1799, it was declared one of the seven islands formed into a republic. N. lat. 39° 4'. E. long. 20° 39'.

MAUREPAS, John Frederic Philippeaux, *Count de*, in *Biography*, a French statesman, was born in 1701, and in 1715 was appointed secretary of state; which, considering his youth, must have been a sinecure. In 1723, he was made superintendant of the marine, and, in 1738, minister of state. By the intrigues of madame Pompadour he was exiled to Bourges in 1749. He was not recalled till 1774, when Louis XVI. entrusted the public affairs to his management. He attended greatly to the marine department, and was a liberal encourager of the sciences; but the part he took in assisting America against England is a reflection on his political prudence. He died in 1781. His Memoirs, by himself, are curious, but carelessly written; they were printed at Paris in 1792, 2 vols 8vo. Nouv. Dict. Hist.

Maurepas, in *Geography*, an island on the N.E. coast of lake Superior, in Upper Canada, N.E. of Portchartrain island, about half way between Elbow island and the bay of Michipicoten; 40 miles in circumference. N. lat. 47° 42'. W. long. 85° 30'.—Also, an island on the coast of cape Breton, the same as the "Isle Madame;" which see.—Also, a lake in West Florida, communicating westward with the Missisippi river, through the gut of Ibberville, and eastward with lake Portchartrain; ten miles long and seven broad.

MAURIAC, a town of France, and chief place of a district, in the department of the Cantal; 18 miles N.N.W. of Aurillac. The place contains 2572, and the canton 11,337 inhabitants, on a territory of 250 kiliometres, in 11 communes.

MAURICE, (Mauritius), in *Biography*, emperor of the East, was born, about 539, at Arabissus, in Cappadocia. He entered at an early age into the army, and was, on account of his prudence and valour, placed by the emperor Tiberius Constantine at the head of the army sent against the Persian king Hormisdas. He gained two victories over the Persians, and returning to Constantinople, was rewarded with the hand of the emperor's daughter, and the high dignity of Cæsar. At the death of Tiberius, in 582, Maurice succeeded to the throne without opposition. War was renewed with doubtful success, but in the end Hormisdas was deposed, and Chosroes, with the assistance of Maurice, was placed on the Persian throne. Peace was now restored between the two emperors, after which the arms of the emperor were turned against the Avars, a barbarian tribe on the Danube, who had made incursions into Thrace: of these it is said that 60,000 were slain, and a great number taken prisoners. The enemy, however, in the same contest, captured 12,000 of the soldiers in Maurice's army, which they put to death on the refusal of their king to pay a ransom for their lives and liberty. This and other circumstances rendered him extremely unpopular among the troops; and upon the arrival of an order for them to cross the Danube into the enemy's country, they broke out into a general mutiny, and marched back to Constantinople. The populace in that city, partaking

taking in the disaffection, rose in revolt, and assaulted the emperor with stones. He was now glad to make his escape to the Asiatic shore, whence he sent his eldest son to implore the protection and assistance of the Persian king. Phocas, a centurion, had been invested with the purple, and as the emperor quitted the capital he entered it, and was consecrated by the patriarch. Shortly after this he sent his executioners to prevent the possibility of future rivalship. They dragged the unfortunate man from his sanctuary, and having murdered five of his children before his face, slew him in the twentieth year of his reign, A.D. 602. Maurice is highly extolled by ecclesiastical historians for his piety and orthodoxy, and it is generally admitted that he was a virtuous character, possessed of very good intentions, though certainly unequal to his high station. He was well acquainted with the military art, and composed twelve books on the subject, which are still extant. They were published in 1664, at the end of the Tactics of Arrian. Univer. Hist. Gibbon.

Maurice, elector of Saxony, son of Henry the Pious, of the Albertine branch of the Saxon family, was born in 1521. He came to the possession of his territories when he was about twenty years of age, at which time he was distinguished by gracefulness of person, and great dexterity in all martial exercises. He had been educated in a zealous attachment to the Protestant doctrines, yet, when the princes of that persuasion entered into the league of Smalcalde in defence of their civil and religious liberties, he refused to join in it, and attached himself to the party of Charles V. His cousin, John-Frederick, then elector of Saxony, was one of the chiefs of that league; and the unjust design of supplanting him, with the view of making himself the head of the house, was probably the spring of his conduct from his first appearance as a public character. At the diet of Worms, in 1545, he differed from his Protestant brethren, by shewing an inclination to gratify the emperor, in opening a communication with the council of Trent, and granting an aid towards the Turkish war. In the following year, when the Protestant confederacy declared war against Charles, Maurice made a secret treaty with him, by which he engaged to assist him as a faithful subject, stipulating that he should be rewarded with the dignity and territories of which his kinsman, the elector, might be despoiled. He, nevertheless, lulled the suspicions of the other party, till he actually invaded and took possession of almost the whole electorate of Saxony. For this he was branded with the names of traitor and apostate, and became the theme of the bitterest invectives from the pulpit and the press. The elector soon after recovered his dominions, and not contented with this, he seized upon a part of the hereditary possessions of Maurice. His success was short-lived, for in 1547 he lost his sovereignty and his liberty, and his antagonist Maurice was, in the same year, formally invested in the electoral dignity at the diet of Augsburg. He now entered most fully into the emperor's views, and joined him in the project to reduce the whole Germanic body to a state of subjection; nor was it doubtful that the final ruin of Protestantism was a part of his determination. Maurice, sincerely attached to his religion, and feeling his consequence as its head in Germany, resolved henceforth to appear in a character suited to his station and principles. He enforced throughout Saxony "The Interim," or temporary plan of religion, which was to continue till its final settlement, but which was highly obnoxious to the zealous Protestants. In this he was supported by Melancthon and others of the moderate party. He still professed a full adherence to his alliance with the emperor, but as his own plans approached nearer to execution, he strengthened himself by a treaty with the French king, Henry II, the professed object of which was to restore the landgrave of Hesse to liberty, and to preserve the German constitution. At length, in March 1552, Maurice suddenly joined in Thuringia a considerable army which he had collected, and issued a manifesto containing his reasons for taking arms. The king of France added one in his own name, and both their forces began to act. Maurice now threw off the mask very completely, he advanced into Upper Germany, at every place restoring the magistrates whom the emperor had deposed, and reinstating the Protestants in the churches from which they had been ejected. By hasty marches, attended with great success, he proceeded towards Inspruck, where the emperor then was. A temporary mutiny among his troops gave that powerful monarch time to escape out of the town in a litter by torch-light, before Maurice entered it. He fled across the Alps, having first liberated the former elector of Saxony; the council of Trent broke up in confusion, and the affairs of Germany assumed a totally new face. Negociations for peace were opened at Passau, where Maurice appeared at the head of the Protestants, and Ferdinand, king of the Romans, represented his brother the emperor. Maurice's demands were supported by the princes of the empire, as well Popish as Protestant, and the emperor found it necessary to enter into terms of accommodation. At length the "Peace of Religion," as it was called, was concluded at Passau, in August 1552, by which the landgrave was to be set at liberty, a diet was to be holden within six months for setling all religious dissentions, and in the mean time each party was to enjoy equal privileges, and the undisturbed exercise of its religion. Thus Maurice, who, by his conduct, had been suspected of apostacy from the Protestant cause, had the glory of establishing the reformation in Germany upon the solid basis on which it has ever since subsisted. After this treaty was agreed on, and signed, he accompanied Ferdinand into Hungary at the head of 20,000 men, in order to take the command of the Turks, but mutinies among the troops and dissentions between the generals prevented him from doing any thing worthy of his reputation. In the following year a confederacy was formed against Albert of Brandenburg, of which Maurice was appointed commander-in-chief, and on the ninth of June, 1553, the two armies met at Sievenhausen, when a fierce engagement ensued, which ended in Albert's total defeat. But the victors had to deplore the loss of many brave officers of distinction, among whom was Maurice himself, who, on leading a body of cavalry to a second charge, was shot in the belly with a pistol-bullet, of which wound he died two days after, in the thirty-second year of his age, and the sixth from his possession of the electoral dignity. Univer. Hist. Robertson.

Maurice of Nassau, son of William prince of Orange, by his second wife Ann, daughter of the preceding Maurice of Saxony, was about eighteen years of age, and a student in the university of Leyden, at the time of his father's assassination in 1584. Upon that fatal event he was appointed by the states of Holland and Zealand their stadtholder and captain-general, and soon after he took his post as an antagonist of the prince of Parma, the most celebrated general of that age. In 1590 he made himself master of Breda; and in the following year, being created stadtholder of Guelderland, he took several important places, ending with Nimeguen, by which he acquired a very high degree of popularity and fame. In 1593 he captured the strong fortress of Gertruydenberg, which raised him to a parity with the ablest generals of the time, and he appeared to unite with vigour and enterprize of youth all the caution and

and vigilance that are usually the result of age and experience. Attempts were made to take away his life, but they were unsuccessful, and he continued for many years in an uninterrupted course of military transactions, and gradually recovered almost all the places within the seven provinces which had been taken by the Spaniards. He gained the memorable battle of Nieuport against the archduke Albert. Several towns fell into his hands in consequence of this success, though he ever after reflected upon himself for putting his country to such a risk as was incurred by this action. After the death of the prince of Parma, Maurice had next Spinola for his antagonist. Every stratagem of war was exhausted in the campaigns between these two masters of the military art, who balanced each other's success. The Spaniards now began to be tired of war, and negociations were entered upon for a peace, but Maurice threw obstacles in the way of an accommodation, while, on the other hand, the constitutional republicans, at the head of whom was the grand pensioner of Holland, Barneveldt, were on that account the more solicitous to promote it, and in the end they carried their point, and a truce for twelve years was concluded in April, 1609. From this period Maurice appears chiefly in the less respectable light of head of a party, and aiming at a degree of power and influence not at all compatible with a free constitution. Religious disputes succeeded the external tranquillity of Holland: these gave Maurice a pretext to interpose with a strong hand, by virtue of his office as stadtholder. The Arminian doctrine was embraced by Barneveldt, Grotius, and many other illustrious characters, who united sentiments of religious liberty with republican politics. These, however, were the smaller number, and Maurice threw all his influence into the scale of their enemies, who would not acquiesce in a proposal for an equal toleration of Calvinists and Arminians: they demanded a national synod to settle their disputes, not doubting that their party would be found to be the majority. To this proposal Maurice lent his assistance, and at length, in 1618, the famous synod of Dordrecht or Dort was assembled. The result of its deliberations was the absolute condemnation of the doctrines of Arminius, and of those who held them. Maurice now exhibited in his own conduct and character the traits of a vile and infamous persecutor, for every man who lifts his arm against the rights of conscience ought, in right, to be held up as infamous: he ordered the apprehension of Barneveldt, Grotius, Hoogenberts, and other heads of that party, who were imprisoned in the castle of Louvenstein. Barneveldt was brought to trial, and though innocent of the charges exhibited against him, was condemned to death by a pusillanimous and iniquitous court, and no intercessions could avert the fate of one whom the prince was so much interested to remove. He died a martyr to his principles, and his death not only fixed an indelible stain on the memory of this prince, but greatly injured his popularity, as soon as the nation became cool enough to estimate the man they had lost. The truce between Spain and Holland expired in 1621, and a renewal of war followed, but Maurice's military transactions were not now remarkable; they were thought to denote the languor of broken spirits and declining health. A conspiracy was formed against his life by the younger son of Barneveldt, joined by some zealous Arminians: it was, however, discovered, and the leaders in it executed. Maurice died at the Hague in 1625, in the fifty-eighth year of his age. He had spent the greater part of his life in the service of his country, of which he was, notwithstanding his defects, considered the preserver, and was unquestionably the greatest statesman and warrior of the period in which he flourished. Vigilant, indefatigable, penetrating, cautious, and sagacious, he united all the qualities of a general and a hero with the knowledge of a scholar. Ambition, said to be the weakness of a great mind, was his only foible; this rendered him dangerous to that liberty which he had before nobly asserted. There was no part of the science of war with which he was not thoroughly acquainted, but he particularly excelled in the art of fortification, and in the selection of strong posts. He cultivated a taste for the fine arts, and his temper and talents were calculated to support a tottering cause and render it triumphant, and he has been regarded as one of the founders of Batavian independence. Univer. Hist.

MAURICE, or *Morris*, in *Geography*, a river of New Jersey, whic runs southerly through Cumberland county, into Delaware bay; navigable for vessels of 100 tons ten miles, and for smaller craft considerably further.

MAURICE *Bay, St.*, a bay on the W. side of cape Farewell island, or south extremity of East Greenland, and the principal harbour of that sea.—Also, a bay on the S. coast of the island of Java. N. lat. 7° 38′. E. long. 109° 3′.

MAURICE *Port*, a small cove, which has anchorage before it, in 12½ fathoms, about half a mile from the shore, over coral rocks, on the E. coast of Terra del Fuego island, on the W. shore of Le Maire straits, between that island and Staten Land, on the E. and N. of the bay of Good Success.

MAURICE, *St.*, a town of Switzerland, in the Vallais, situated between the two chains of mountains that bound this country in their approach towards the Rhone The town is built almost totally upon the rock, at the foot of steep mountains, and at a small distance from the river. This was anciently called "Agaunum;" and the name of St. Maurice is derived from an abbey erected in the beginning of the sixth century, by Sigismond, king of Burgundy, in honour of a saint who is supposed to have suffered martyrdom in this place: he was, as tradition says, the leader of the famous Theban legion, reported to have been massacred by the order of Maximin, for not renouncing Christianity. A few Roman inscriptions, chiefly sepulchral, and two defaced columns, are the only incontrovertible remains of the antiquity of St. Maurice. It is principally distinguished as being the chief entrance from the canton of Bern into the Vallais. This entrance is formed by a narrow pass, so strongly fortified by nature, that a small number of men might defend it against a considerable army. The stone bridge over the Rhone is much admired for its bold projection; it is of a single arch, and the span is 130 feet. The pass just mentioned is a great thoroughfare for all goods and persons from the lake of Geneva, through the country of Vallais, and over mount St Bernard; 35 miles E. of Geneva. N. lat. 46° 15′. E. long. 6° 52′.—Also, a town of Canada, on a river of the same name; 9 miles N.W. of Trois Rivieres.—Also, a town of France, in the department of Mont Blanc; 11 miles N.N.W. of Chambery, and another in the same department; 24 miles W. of Aosta.—Also, a town of France, in the department of the Orne; 12 miles N.E. of Mortagne.

MAURICE, *St.*; and *St. Lazarus*, an order of knights in Savoy. The order of St. Maurice was instituted in 1440, by Amadeus VII. duke of Savoy, who was afterwards pope, by the name of Felix V. He assigned for its badge a cross pomettée, made either of white taffeta, or of white linen cloth, placed on the knight's breast. In the year 1572 Philibert, duke of Savoy, being made grand-master of the order of St. Lazarus, which, in 1565, had been renewed in Savoy by pope Pius IV., obtained permission from Gregory, then pope,

pope, for the union of the two orders; ever since which time they have been styled the order of St. Maurice and Lazarus. When this union was effected, the badge was a cross pomettée argent, upon a cross of eight points vert; being the respective badges of the two orders before they were united, and to be worn pendent to a green ribband.

MAURICEAU, Francis, in *Biography*, a surgeon, eminent in the practice of midwifery, was born at Paris, where he applied, with great industry, to the study and practice of surgery, for many years, especially in the great hospital of that city, the Hôtel-Dieu. He had already acquired there so much experience in the obstetrical department of practice, before he commenced public practice, that he rose almost at once to the head of his profession. His reputation was farther increased by his writings, and maintained by his prudent conduct and acknowledged skill during a series of years; after which he quitted practice entirely, and retired into the country, where he died, in October 1709. He published the following works, all relative to the particular branch of the art which he practised; they contain a great store of useful facts, though ill arranged, and mixed with false reasoning peculiar to his time. 1. "Traité des Maladies des Femmes grosses, et de celles qui sont accouchées," Paris 1688, in 4to. which has been often reprinted, and translated into Latin, as well as into most of the modern European languages. 2. "Aphorismes touchant l'Accouchement, la Grossesse, et les Maladies des Femmes," ibid. 1694, which contains a summary of the doctrines of his larger work. 3. "Observations sur la Grossesse et l'Accouchement des Femmes, et sur leurs Maladies, et celles des Enfans nouveaux nés," ibid. 1695, 4to. This may be considered as a second volume of the first treatise, and contains a great number of cases and observations, in illustration of the doctrine there stated. 4. "Dernieres Observations sur les Maladies des Femmes grosses et accouchées," 4to. ibid. 1708; which contains an additional collection of cases. The whole of these works were collected, and reprinted together, after his death, in 1712, and subsequently with figures. Eloy. Dict. Hist. Gen. Biog.

MAURIENNE, or Morienne, *County of*, in *Geography*, was lately a province of Savoy, consisting of a long narrow valley; it now belongs to France, and is included in the department of Mont Blanc.

MAURIPIDA, one of the Laccadive islands. N. lat. 10° 58'. E. long. 72° 21'.

MAURITANIA, Mauretania, or, as it is called by Strabo, *Maurusia*, in *Ancient Geography*, a considerable part of the northern region of Africa, extending from Numidia towards the east to the Atlantic ocean on the west. Mauritania Propria, or Tingitania, considered as unconnected with Mauritania Cæsariensis, was bounded on the E. by the river Malva or Mulucha; on the W. by the Atlantic ocean; on the S. by Gætulia or Libya interior; and on the N. by the Mediterranean. This kingdom, being reduced to the form of a Roman province in the reign of Claudius, was denominated by that prince Mauritania Tingitana; and it was called by the Romans at that time, as well as afterwards, Tingitana, from its principal city Tingi or Tingis, and thus distinguished from Mauritania Cæsariensis. The Tingitania of the ancients very nearly corresponds to the kingdoms of Fez and Morocco. As to the extent of Mauritania properly so called, it may be estimated by considering that the Malva or Mullooïah, its eastern limit, about 1° 15' W. of London, is rather more than 240 miles distant from the Atlantic ocean. Some modern geographers make the kingdom of Fez to be 270 miles long, and that of Morocco, from cape Non to the mountains which divide it from Segelmessa above 370; but this computation, with respect to the ancient Tingitania, is, without doubt, more erroneous than that of Pliny, which amounts only to 170 miles.

Mauritania and Maurusia, the names of this country, are derived from the Mauri, an ancient people who inhabited it; and Bochart considers Maurus as equivalent to Mahur; or as an elision of gutturals is very common in the Oriental language, Maur, *i.e.* one from the west, or an occidentalist, Mauritania being west of Carthage and Phœnicia. As to the origin and general history of the Mauritanians, we may direct our attention to three principal epochas. 1. The period during which the first population, derived from Mizraim by his sons and grandsons, extended from the E. to the W. 2. That in which the Canaanites, expelled from Palestine by Joshua, traversed sea and land to escape from his victorious and destructive arms, established themselves along the coasts of Africa, and partly in the interior of the country. To this purpose Procopius says, that in his time two pillars of stone were to be seen in this country, with the following inscription in the Phœnician language and character upon them: "We are the Canaanites who fled from Joshua, the son of Nun, that notorious robber." 3. The time when the Phœnicians, impelled by the activity of their commercial spirit, formed upon these coasts considerable establishments. We might also mention an influx of Arabians, who came here from Arabia Felix, in the first century of the Christian era, and the invasion of the Mahometan Arabs, in the seventh and eighth centuries. This country, it is well known, bore the name of Barbary, of which there are several derivations. To those that occur under Barbary, we shall here add, that the name may be formed from the oriental "Bar-Barca," or the sea of Barca, a town of the Pentapolis, called afterwards Ptolemais.

The Mauritanians, according to Ptolemy, were divided into several cantons or tribes, which it is needless for us now to enumerate. The metropolis of Tingitania was Tingis or Tingi; which see. Some of its other principal towns were, Zelis, supposed by some to be the modern Arzilla:—Lixus, the residence of Antæus, who was here vanquished by Hercules, and not far from the gardens of the Hesperides; conjectured to be the present Larache:—the city of Hanno, called Thymiaterion:—Sala, near a river of the same name, not far from the Atlantic ocean:—the port and town of Rutubis, 213 miles S. of Lixus:—the Exilissa of Ptolemy, supposed to be the Ceuta of the moderns:—Rusadir, presumed to be Melila or Melilla; and in the interior of the country, the Ascurum of Hirtius:—Herpis:—Volubilis, supposed to be the modern Fez:—Gilda, corresponding to Mequinez:—Prisciana:—the Tocolosida of Ptolemy, perhaps the modern Amergue; the Trisidis of Ptolemy:—Gontiana, answering to a small town between Fez and Mequinez, called Gamaa:—Banasa:—Chalce:—Calamintha, &c. &c. Among the rivers of Tingitania we may mention the Malva, Molochath, Mulucha, or Mullooïah; the Thaluda, Taluda, or Tamuda; the Lixus; the Subur; the Sala, &c. &c. The chief capes or promontories of Tingitania were, the Metagonitis of Ptolemy, and Metagonium of Strabo; the Sestiarium promontorium of Ptolemy, or the Russadi of the Itinerary; the promontorium Oleastrum; the Phœbi promontorium; the cape Cottes or Ampelusia, now cape Spartel; Mons Solis; promontorium Herculis; and Usadium. Among the principal mountains we may rank Abyle or Abyla or Abenna, called by the ancients one of Hercules's pillars, and by our countrymen Apes hill; the Septem fratres of Mela, or Heptadelphi of Ptolemy, near Abyla; mount Cotta not far from the Lixus; and mount Atlas. The chief ports of this country were Rusadir, Sinus Emporicus,

Cotta,

Cotta, Rutubis, and Myſocaras. The principal iſlands on the coaſt of Tingitania were the Tres Inſulæ of the Itinerary, N.W. of the Mulucha; Gezira or Jezeirah, in the river Lixus, about three leagues from the ſea, where the ancients placed the Heſperides; Ptolemy's Pæne and Erythia, two obſcure iſlands in the Atlantic; the latter of which is now called Mogador; the Inſulæ Purpuraſiæ, ſaid by Hardouin to be Madeira and Porto Santo; and the Inſulæ Beatæ, or Fortunate iſlands, of which ſome reckoned ten, others ſeven, and others three.

The government of Mauritania, from the earlieſt ages, is ſaid to have been an abſolute monarchy. However Appian ſays, that ſeveral tribes of Moors were governed by their own laws, or at leaſt under the direction of their own chiefs and leaders, in oppoſition to that form of government which was eſtabliſhed in the greateſt part of this country. The independent Arabs, mentioned by Dr. Shaw in his Travels, who are ſeated in the kingdom of Algiers and Tunis, and who ſometimes hover about the frontiers of Morocco, may probably be the poſterity of theſe free-born Moors. Whether this be allowed or not, moſt of the provinces of Mauritania, if not the whole country, were ſubject to one prince in the reign of the elder Dionyſius. It appears alſo from Juſtin and Appian, that at ſubſequent periods they had ſovereigns, but it is likely that they exerciſed their ſovereign authority according to fixed laws, or certain political maxims, which directed the conduct of their rulers.

As to their religion, Neptune was one of the principal objects of their adoration. They likewiſe paid religious honours to the ſun and moon, in common with the other Libyan nations. Seneca aſſerts that they offered human ſacrifices to their gods, in imitation of the Phœnicians and Carthaginians, or ſome other ancient people, from whom they derived their origin. Bacchus was alſo worſhipped by the Mauritanians; and, in ſhort, we may form a notion of their religion from that of the Egyptians, Phœnicians, Perſians, and Carthaginians. Their language and character ſcarcely differed from thoſe of the Numidians. As to their cuſtoms and habits, they at firſt uſed only clubs in their military conflicts, till they were taught the uſe of the ſword. All perſons of diſtinction were clad in rich apparel, ornamented with gold and ſilver, and they took great pains in curling their hair, curiouſly and elegantly, cleanſing their teeth, combing their beards, which were long, and paring their nails. In time of action the Mauritanian infantry uſed ſhields made of elephants' ſkins, and they were clad, both night and day, in thoſe of lions, leopards, and bears. The cavalry were armed with broad ſhort lances, and carried targets or bucklers, made of the ſkins of wild beaſts. They uſed no ſaddles. Their horſes were ſmall and ſwift, and ſo much under command, that they would follow them like dogs. Herodotus intimates, that the ſhield and helmet came from them to the Greeks. Notwithſtanding the fertility of their ſoil, the poorer Mauritanians never attended to agriculture, but roved about the country in a wild ſavage manner, like the ancient Scythians or Arabian Scenites. They lived in ſmall and inconvenient tents; their food was corn and herbage, which they frequently ate green, and without any preparation; their habit was the ſame in ſummer and winter, and conſiſted of a tattered, though thick, garment, covered with a coarſe rough tunic; they repoſed on the ground, ſometimes ſpreading their garments under them, as the African Kabyles and Arabs now do. According to a paſſage in Horace, they ſhot poiſoned arrows; in preparing and uſing which they were ſkilful, having acquired the art from ſelf-defence againſt the wild beaſts, to which they were expoſed. With regard to the arts and ſciences, the Mauritanians were rude and barbarous; but if they excelled in any art, it muſt have been in navigation. To magic, ſorcery, and divination, they were much addicted. Strabo differs from Mela in his deſcription of Tingitania; for he repreſents it, not as poor and deſpicable, but as an opulent kingdom.

The hiſtory of the Mauritanians preſents to our notice nothing remarkable, except the defeat of Antæus, till the Roman times. Salluſt informs us that nothing of the Mauri, except their name, was known to the Romans ſo late as the Jugurthine war; and the moſt ancient Greek writers conſidered them merely as a branch of the Libyans. Bogud, king of Mauritania, who was contemporary with Julius Cæſar, contributed very much to his great ſucceſs in Africa; and he aſſiſted him alſo in Spain. After Cæſar's death, he joined Antony againſt Octavius, but when he attempted to make a diverſion in Spain, in favour of the former, the Tingitanians revolted, and being ſupported by Bocchus's troops in the intereſt of Octavius, Bocchus ſucceeded and was put in poſſeſſion of Tingitania, and Octavius granted to the inhabitants of Tingis the privileges of Roman citizens. After Bocchus's death, Tingitania was reduced to the form of a Roman province. Auguſtus gave the younger Juba the two Mauritanias, together with part of Gætulia, ſome time after his marriage with the younger Cleopatra, inſtead of his father's kingdom, *i. e.* Numidia, which ſtill remained a Roman province. The Mauritanians, however, did not quietly ſubmit to the Roman yoke. At the commencement of the reign of Tiberius, Tarfarinas, a Numidian ſoldier, enterpriſing and courageous, famed among the Romans in the art of war, entered into a confederacy with ſome diſcontented Moors, and refuſed to acknowledge the authority of Rome. Tarfarinas was defeated by the proconſul Cornelius Dolabella. In this war Ptolemy, the ſon of Juba II. and grandſon of Juba I. rendered very conſiderable aſſiſtance to the Romans. However, he was put to death under Caligula. Eudemon, his freedman, raiſed an army in order to avenge his death. Claudius, who ſucceeded Caligula, ſent an army againſt the Moors, and they were completely defeated.

In conſequence of a treaty of peace between the two commanders, Mauritania was delivered entirely into the hands of the Romans; for we find it ſoon after divided into two provinces, the one called Tingitania, or Mauritania Tingitana, from the city Tingis, and the other Mauritania Cæſarienſis, from Cæſar, a ſurname which Claudius had in common with the other Roman emperors.

The Mauritanians, being completely ſubjected to the Romans, returned to their cuſtomary occupations, and having abandoned a military life, devoted themſelves to the care of their lands, herds, and flocks. But the diſſentions that occurred on occaſion of the pretenſions of Otho and Vitellius to the empire, put them again in motion. Under the immediately ſucceeding reigns nothing very material occurred; but under the empire of Diocletian, they engaged in a conteſt with Maximin, his aſſociate in the empire. In this conflict they were great ſufferers; being obliged to deliver up their arms and to abandon their country. After the abdication of Diocletian, they were involved in new troubles. The troops of Africa revolted and proclaimed Alexander their lieutenant; upon which they were attacked and defeated by Maxentius.

Conſtantine, after his acceſſion, granted ſingular privileges to the African churches, which ſoon became very numerous. But when the ſeat of government was transferred to Byzantium by Conſtantine, the diſtant provinces were abandoned to the oppreffion of their governors. The Mauritanians fuffered, and their country was once and again the fcene of tumult and of war. When the Vandals were deftroyed in Africa under the reign of Juftinian, by the activity of Belifarius, the Mauritanians found themfelves expofed to the tyranny and oppreffion of Greek prefects. The people revolted; and at length, under the empire of Heraclius, the caliphs having conquered Egypt and Syria, fent an army on their coaft. The whole country, as far as the columns of Hercules, fubmitted to their domination, under which it has more or lefs continued. See Moors.

Mauritania *Cæfarienfis*, or *Cæfariana*, a part of Mauritania fo denominated under the reign of Claudius. This province had been feparated from Numidia: it extended from Mauritania Tingitana, from which it was feparated by the river Malva on the weft as far as the Ampfagee. See Numidia.

Mauritania *Sitifenfis*, a part of Mauritania Cæfarienfis on the eaftern fide, adjacent to Numidia, fo called from Sitifi, a town in that territory.

MAURITIA, in *Botany*, a Palm fo named by the younger Linnæus, after the appellation by which it is known to the Dutch fettlers in Surinam, *Mauritii-Boom*, or Maurice tree. Whether this appellation originated in any compliment to the memory of their great prince Maurice, or of any other perfon of the fame name, or whether the tree were thought to have been brought from the ifland of Mauritius, we are not informed.—Linn. Suppl. 70. Schreb. 779. Mart. Mill. Dict. v. 3. Juff. 40. Lamarck Dict. v. 3. 739.—Clafs and order, *Dioecia? Hexandria.* Nat. Ord. *Palmæ.*

Gen. Ch. Male an oblong feffile *catkin*, covered entirely with clofely crowded flowers, having obtufe fcales between them. *Cal.* Perianth of one leaf, cup-fhaped, abrupt, entire, triangular, fhort. *Cor.* of one petal; tube fhort, the length of the calyx, with three futures, by which the divifions of the limb are eafily continued down to the bafe; limb in three deep, equal, flightly fpreading, lanceolate, obtufe, channelled, rigid, and almoft woody, fegments. *Stam.* Filaments fix, thick and very fhort, inferted into the mouth of the tube; anthers linear, angular, the length of the corolla, three of them fpreading horizontally between its fegments, the alternate three erect, clofely preffed to the channel of each fegment.

Female unknown.

Eff. Ch. Male an oblong feffile catkin. Calyx of one leaf, cup-fhaped, undivided. Corolla of one petal, with a fhort tube, and three-cleft limb.

1. M. *flexuofa.* Linn. Suppl. 454. Syft. Veg. ed. 14. 986.—Sent, from the woods of Surinam, by Dalberg, being a part of the botanical collection, preferved in fpirits of wine, which king Guftavus III. of Sweden prefented to Linnæus. (See Gustavia.) It is defcribed as a nearly leaflefs *tree*, with angular, zigzag, fmooth *branches*, compofed of fhort joints fwelling upwards and fomewhat recurved, each joint terminating in a cup-like, doubly-pointed *fheath*. From thefe *fheaths*, over the whole ftem, fpring folitary feffile *catkins*, of an ovate-oblong cylindrical figure, rather above an inch in length, widely fpreading in two ranks, each having at its bafe a pair of larger erect falcate fcales. The flowers are of a rufty hue, at leaft in the preferved fpecimens, and clofely cover the whole catkin, ftanding at a right angle with its common ftalk. The *fcales* which feparate the flowers are round and obtufe, fmaller than the pair at the bottom of the catkin. The *flowers* fall when faded, leaving the catkin and its fcales permanent. Linnæus juftly fpeaks of this tree as very fingular, being almoft deftitute of foliage, and laments that he knew nothing of the female flowers or fruit. Thefe are prefumed to be borne on a diftinct individual.

Mauritia, in *Gardening*, comprehends a plant of the exotic tree kind, of which the fpecies cultivated is the maidenhair tree, or ginkgo, (M. flexuofa.)

Method of Culture.—It may be increafed by laying down the young branches in the fummer feafon, and when they have ftricken root fully, taking them off and planting them with earth about their roots in pots filled with light frefh mould, placing them in the greenhoufe, where they muft be kept.

And the cuttings of the young fhoots may alfo be planted in pots in the fame manner, plunging them in a moderate hotbed till they have ftricken root, when they may be managed as the other plants are directed to be.

This plant affords variety in the greenhoufe, and when trained againft walls; but in the laft cafe muft be fheltered by mats, in fevere weather in the winter feafon.

MAURITIO, St., in *Geography*, a town of France, in the department of the Po; feven miles N.N.W. of Turin.

MAURITIUS, or *Ifle of France*, an ifland in the Indian fea, firft difcovered by the Dutch in 1598, and fo called by them in honour of the prince of Orange. On their firft arrival the Dutch anchored with a fleet of five fhips in a fafe port capable of containing 50 large veffels, and which, in honour of their vice-admiral, they called Warwick's Haven. The country was found to abound with cattle, fowl, fifh, and fruits; and afforded a feafonable fupply of neceffaries to the crew and of refrefhments to the fick, who went on fhore for their recovery. Of the importance of this ifland they were fufficiently apprifed, infomuch that they recorded in their journals an obfervation, that it might be commodioufly vifited by outward bound fhips, as that of St. Helena might be on their return: neverthelefs, they made no fettlement in this ifland for forty years, and they were juft in time to preclude the French from taking poffeffion of it. They had the precaution to build a fort for the defence of the haven and watering place; and in 1640 they had two or three fmall fettlements in the ifland, befides their fort. But as they wanted flaves to cultivate their plantations, they applied to the French governor of Madagafcar, and prevailed upon him to fteal 50 blacks out of the number of thofe who were under his protection. This fraudulent act induced the people of Madagafcar to withdraw their confidence from the French; and as to the negroes that were carried to Mauritius, many of them fled into the woods and mountains, where they became robbers or banditti, or, as they are denominated in the Weft Indies, maroons. Thefe were joined by other perfons of a fimilar defcription, and became fo powerful, that the Dutch, notwithftanding their garrifon of 50 men in the fort, could not fecure themfelves againft their infults and depredations. About the beginning of the laft century, the Dutch Eaft India company in Holland determined to abandon it; and actually withdrew their colony from it in 1712, and removed it to the Cape of Good Hope. The ifland, fays the Abbé Raynal, was uninhabited when the French landed there in 1720, and changed its name from Mauritius to the Ifle of France, which name it ftill bears. Its firft inhabitants, he fays, came over from the Ifle of Bourbon; but it remained in a neglected ftate for almoft fifteen years. At length, in 1734, the French company refolved to make fome important fettlement here, and the project was entrufted to the execution of Mahe de la Bourdonnais. As foon as he arrived he was indefa-

indefatigably active in executing every plan for the improvement of the island, which his sagacity devised: and to him the French were afterwards indebted for aqueducts, bridges, hospitals, and storehouses. Exciting by his example a spirit of emulation and industry in the colonists, he changed the whole aspect of the island and the condition of its inhabitants, during the twelve years of his administration. By his recommendation the French made choice of the harbour to the N.W. of this island, in preference to that which is more spacious and more commodious to the S.E.; a harbour to the leeward possessing many advantages in latitudes where the general winds prevail. The spirit which he excited led the inhabitants to the cultivation of corn, which became the most prosperous of all the branches of agriculture practised at this island; where the fields yield annually in regular succession a crop of wheat and another of maize or Indian corn. The manioc or cassava, which was brought from Brazil by M. la Bourdonnais, served as common food to the blacks. In consequence of the improvements of this governor, ships going to India found all the refreshments and conveniences they wanted after a tedious passage. The continual supplies afforded to ships and squadrons have contributed to check the increase of cattle, which it was the object of La Bourdonnais to multiply. However, the island produces excellent pasture, which springs up in the beginning of the rainy season. It completes the whole course of its vegetation in the course of three months, during which interval the inhabitants feed their herds. This island has occasionally suffered much from hurricanes, so that the colony has been preserved by the attention of the governor in procuring supplies from the Cape of Good Hope. The cultivation of corn in this island has been much promoted by M. Poivre; and in a variety of other ways, particularly by introducing the nutmeg and clove, and the rice of Cochinchina, he contributed to enrich the colony entrusted to his care. M. Cerè procured from Ceylon, and planted in this island, of which he was governor, a great number of cinnamon, clove, and nutmeg trees, which have been very prosperous. But in 1786, the Dutch, actuated by the true spirit of monopoly, sent a vagabond to the island in order to destroy these plantations; but the plot was discovered in time, and the vagabond escaped merited punishment.

The soil of this island is, generally speaking, red and stony; towards the sea-coasts it is mountainous, but within land there are many spots both level and fertile. Some of the mountains are high, but none exceed 426 fathoms in elevation: it is said, however, that their summits are covered with snow throughout the year. The whole island is well watered; and it produces all the trees, fruits, and herbs, which grow in this part of the globe, in great plenty; groves of oranges as well as citrons; and the pine-apple grows spontaneously in great perfection. The chief produce is sugar. When this island was first discovered, the ground was covered with wood up to the summits of the mountains, so that it was one immense forest full of beautiful trees. M. Rochon observed in it different kinds of the palm-tree, bamboos, ebony, mat-wood, tacamaca, stinking wood, and many other kinds of valuable trees. No venomous animals, except scorpions and millepedes, are known here. For fineness of climate, and salubrity of air, this island, as well as that of Bourbon, may be compared with the Fortunate islands. The whole extent of the island is about 150 miles, and its form is nearly circular. The population, in the year 1790, exclusive of the military, was estimated at 8000 whites and 12,000 blacks. This island, the last remains of the French possessions in the Indian seas, was taken by the English, December 2, 1810. S. lat. 20° 12'. E. long. 58° 27'.

MAURO, St., a town of Naples, in Lavora; 4 miles S.E. of Capua.—Also, a town of Naples, in Basilicata; 22 miles S.E. of Acerenza.—Also, a town of the county of Tyrol; 12 miles N.N.E. of Trent.—Also, a town of Naples, in Calabria Citra; 3 miles W.S.W. of Rossano.

MAUROCENIA, in *Botany*, Linn. Hort. Cliff. 108. Gen. ed. 1. 85, was named by Linnæus in honour of Giovanni Francesco Mauroceno, a Venetian senator, who had a very fine and rich garden at Padua, of which a catalogue was published there by Antonio Tita in 1713, being an 8vo of 183 pages, besides 13 pages describing a journey of the author's over the mountains of Trent. This genus was subsequently sunk in *Cassine*, the only species of which it consisted being *Cassine Maurocenia*, Linn. Sp. Pl. 385. See Cassine.

MAUROLICO, or Maurolicus, Francis, in *Biography*, who flourished in the sixteenth century, descended from a noble Greek family, (but driven to seek an asylum in Sicily from the persecution of the Turks,) was born at Messina in the year 1494. He was, at a very early period, distinguished by his proficiency in polite literature, the learned languages, and, above all, in mathematical learning. He devoted himself to theology as a profession; but his favourite studies were those of the belles lettres, and the sciences properly so called. For a considerable time he was professor of mathematics in his native city, and was much followed and admired on account of the great perspicuity with which he explained and illustrated the most difficult questions. His fame, as a mathematician, extended over the whole of Europe. He excelled in geometry, astronomy, optics, and architecture; and he enjoyed the esteem and friendship of the most illustrious persons of his time. He was by his countrymen regarded as their second Archimedes. He restored the fifth book of Apollonius, which had been lost; and he discovered a new method of demonstrating the properties of the conic sections, in which he has been followed by many modern geometers. He made discoveries in the art of dialling, of which he published an account in his "De Lineis Horariis." He wrote on optics, and is mentioned by Dr. Priestley and others as the person who discovered that it is the crystalline humour which collects and unites on the retina the rays which it receives from external objects, and brings every pencil to its proper focus; and by means of it, he was able to explain the phenomena of long and short-sightedness, which had been till then inexplicable. He is said also to have given the first solution of the problem concerning the image of the sun appearing round, though the rays that form it are transmitted into a dark room through an angular aperture. He died at the advanced age of eighty, leaving behind him numerous works, that attest to the greatness of his talents, and his unceasing industry and perseverance, though he was for many years an invalid. His biographers have given the titles of the following as his principal works: "The Spherics of Theodosius;" "Emendatio et Restitutio Conicorum Apollonii Pergæi;" "Archimedis Monumenta omnia;" "Euclidis Phænomena;" "Opuscula Mathematica;" "Arithmeticorum Libri duo;" "Photismus de Lumine et Umbra;" "Problemata Mechanica ad Magnetem et ad Pyxidem nauticam Pertinentia." Priestley's Light and Colours. Moreri.

MAURON, in *Geography*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Ploermel; 10 miles N. of Ploermel. The

 place

place contains 4212, and the canton 9035 inhabitants, on a territory of 192½ kiliometres, in 7 communes.

MAUROUSE, the name of a creature of the deer kind, mentioned by Joſſelyn. It ſeems to be the ſame with the *dama Virginiana* of Mr. Ray, one of which creatures was, in his time, kept alive in St. James's park.

This is not certain, however; for Joſſelyn's deſcription is very imperfect: he only ſays it is like the mooſe-deer, but is ſmall, and has ſmall horns.

MAURS, in *Geography*, a town of France, in the department of the Cantal, and chief place of a canton, in the diſtrict of Aurillac; 18 miles S.S.W. of Aurillac. The place contains 2045, and the canton 11,029 inhabitants, on a territory of 262½ kiliometres, in 13 communes.

MAURSEE, a conſiderable lake of Pruſſia, in the province of Culm; 10 miles E. of Raſtenburg.

MAURUA, or MAUROOA, one of the Society iſlands, in the South Pacific ocean, of ſmall ſize, wholly ſurrounded by a reef, and deſtitute of harbour for ſhipping. It is inhabited, and bears the ſame produce as the neighbouring iſlands. Its middle riſes in a high round hill, that may be ſeen at the diſtance of 10 leagues. S. lat. 16° 26′. W. long. 152°.

MAURUCA, a kingdom on the eaſt coaſt of Africa, ſituated in about S. lat. 14° 30′. E. long. 37° 14′.

MAUSAHEID, or MESEK, a town of Arabia; 35 miles N. of Mocha.

MAU-SIDS, a town of Arabia, in the province of Yemen; 24 miles N. of Mocha.

MAUSOLEUM, a magnificent tomb, or funeral monument, decorated with architecture and ſculpture, and inſcribed with an epitaph; erected in honour of ſome emperor, prince, or other illuſtrious perſon.

The word comes from *Mauſolus*, the name of a king of Caria, to whom Artemiſia, his widow, erected a moſt ſtately monument, that has ſince been numbered among the ſeven wonders of the world; calling it, from his name, Mauſoleum. It was ſixty-three feet long, almoſt four hundred and eleven feet in compaſs, and about thirty-five feet high, ſurrounded with thirty-ſix columns, that were beautified in a wonderful manner. Pliny has deſcribed it, lib. xxxvi. cap. 5. Afterwards the ſame name was given to all coſtly monuments. Thus the ſtately monument was called, which Auguſtus built, during his ſixth conſulſhip, between the Flaminia Via and the Tiber, to be a burial-place for him and his family, and which Strabo has deſcribed in his fifth book. It is alſo the name which Florus, lib. iv. cap. 11. gives to the monuments of the kings of Egypt, wherein Cleopatra ſhut herſelf up, and put herſelf to death. Many authorities teſtify, that the Romans gave this name to thoſe ſepulchres whoſe ſtructure was magnificent.

MAUSOLEUM is alſo uſed to ſignify the decoration of a fictitious tomb, or catafalca, in funeral pomp.

MAUSSAC, PHILIP-JAMES, in *Biography*, a learned critic, was born at Toulouſe in the year 1590, where his father was a counſellor of parliament. He was educated for the profeſſion of the law, and became preſident of the court of aides at Montpellier, where he died in 1650. He was accounted one of the beſt Greek ſcholars of his time. He wrote "Notes and Corrections on Harpocration," "Remarks on the Treatiſe on Mountains and Rivers aſcribed to Plutarch," and various other works. Moreri.

MAUTCHONG-COUNSAN, in *Geography*, a mountain of Thibet. N. lat. 31° 38′. E. long. 83° 44′.

MAUTEN, a town of Carinthia, at the conflux of the Moledin and the Geil; 18 miles S.W. of Saxenburg.

MAUTERN, a town of the duchy of Stiria; 8 miles N. of Windiſch Gratz.

MAUTH, a town of Bohemia, in the circle of Beraun; 18 miles S.E. of Beraun.

MAUTHAUSEN, a town of Auſtria, on the left bank of the Danube; 7 miles E. of Steyregg.

MAUTOUR, PHILIBERT BERNARD MOREAU DE, in *Biography*, auditor of the chamber of accompts at Paris, and member of the academy of inſcriptions. He was born at Beaune in 1654, and died in 1737. He wrote ſome papers in the Memoirs of the Academy of Belles Lettres, and poems. He was alſo the editor of an abridgment of Petavius's Chronology, 4 vols. 12mo. Moreri.

MAUTTERN, in *Geography*, a town of Auſtria, on the ſouth ſide of the Danube, oppoſite to Stein; 32 miles W.N.W. of Vienna. N. lat. 48° 23′. E. long. 15° 38′.

MAUTTERNDORF, a town of the principality of Salzburg; 11 miles S. of Radſtadt.

MAUVEZIN, a town of France, in the department of the Gers, and chief place of a canton, in the diſtrict of Lectoure; 17 miles S.S.E. of Lectoure. The place contains 2005, and the canton 9083 inhabitants, on a territory of 192½ kiliometres, in 26 communes.

MAUVILLON, JAMES, in *Biography*, profeſſor of the military ſciences in the Caroline college at Brunſwick, was deſcended from a French family, and born at Leipſic in 1743. His father being profeſſor of the French language in the Caroline college, he had an opportunity of proſecuting his ſtudies under the celebrated men who, at that time, were an ornament to the ſciences which they taught. The favourite purſuits of the ſon were the languages, drawing, and mathematics. He ſoon diſplayed a ſtrong attachment to a military life; but as this was oppoſed by his father, who wiſhed him to ſtudy the law, he went privately and offered to inliſt himſelf with general Wallmoden. Though his ardour was great, his ſtature was ſo ſmall and diminutive, that the general refuſed to admit him into the ſervice. At length, however, he was received into the corps of engineers; but, at the concluſion of the war, he was, at the perſuaſion of his father, induced to repair to Leipſic to ſtudy the law. His mind was not at all formed for legal ſtudies, and he preferred to theſe the drudgery of aſſiſting in a ſchool. Here he improved himſelf in the Latin language, and ſoon after, on the recommendation of the general, was appointed engineer of bridges and highways at Caſſel, and teacher of the military ſciences. About this period he became a contributor to ſome periodical works, and wrote his "Letters on the Merits of the German Poets," which, on account of the ſeverity of his animadverſions, excited againſt him many enemies. In 1775 he gave proofs of his diligence, as well as his talents, by tranſlating Raynal's "Hiſtory of the Indies," a work of Turgot's, and Arioſto; beſides being engaged in ſeveral journals. In 1777 he was appointed captain of a corps of cadets, and obtained the friendſhip of profeſſor Dohm, afterwards the Pruſſian miniſter. To this perſon he addreſſed his "Phyſiocratic Letters," which were publiſhed in 1780; and in the ſame year he was elected a member of the Society of Antiquaries at Caſſel, and wrote ſeveral papers, which were inſerted in its tranſactions. In 1781 he publiſhed his "Introduction to the Military Sciences," with an Eſſay on the thirty years' war, and another on the influence which the invention of gunpowder has had in modern wars. Theſe were all publiſhed in the French language. His ſituation in the corps of cadets ſubjected him to much uneaſineſs; and about this time he repaired to Potzdam, and ſolicited

solicited an appointment from Frederic II., which would have been readily granted; but he found his wife so averse from settling in Prussia, that he gave up the idea, and returned to his former situation at Cassel. He studied religion as well as military tactics, and in 1787 published what he entitled a "System of Religion." He had, previously to this, formed an acquaintance, which ripened into friendship, with the celebrated Mirabeau. An account of the joint pursuits of these friends may be found in Mirabeau's "Lettres du Compte de Mirabeau à un de ses Amis en Allemagne, ècrites durant les Annees 1786-90." Mauvillon died in 1792. The last work which he published was entitled "Man and Woman," written in opposition to a book by Brandes, in which the female sex had not been treated with that degree of justice which Mauvillon thought due to them. He began a "Life of Prince Ferdinand of Brunswic," which is said to be the best of all his productions. Mauvillon was fond of company; and in the early part of life, the whole object of his labour was that he might gratify his taste without running into debt. In his manners and dress he was exceedingly simple; he had no attachment to wine, but was excessively fond of coffee; he was a zealous advocate for the principles of toleration, and in all kinds of company avowed his sentiments with the greatest freedom. He was friendly to the French revolution, but disapproved of the horrid scenes which attended it. Gen. Biog.

MAUZAT, in *Geography*, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Riom. The place contains 1565, and the canton 9072 inhabitants, on a territory of 242½ kiliometres, in 10 communes.

MAUZE', a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Niort. The place contains 1600, and the canton 6876 inhabitants, on a territory of 145 kiliometres, in 8 communes.

MAW, a sea-port of Ceylon, at the mouth of a river on the west coast; 50 miles W. of Candy. N. lat. 7° 45'. E. long. 75° 55'.

MAW. See ABOMASUS.

MAW-*Skin*, in *Rural Economy*, a provincial word used to signify the stomach of the calf prepared for cheese-making.

MAWAR-UL-NERE, denoting "the country beyond the river, or "Transoxiana," in *Geography*, a country of Independent Tartary, lying beyond the Oxus, or modern Gihon or Jihon; and beyond the lower parts of the courses of that river, and the Sihon, or ancient Iaxartes.

MAWHELLIPOUR, a town of Hindoostan, in Bahar; 3 miles S.W. of Bahar. N. lat. 25° 21'. E. long. 84° 55'.

MAWRI, a sea-port town of Africa, in the country of Sabu, on the Gold coast, inhabited chiefly by fishermen. In the middle of the town is Fort Nassau, built by the Dutch, with a small garrison.

MAWS, ST., a borough town in the parish of St. Just, hundred of Powder, and county of Cornwall, England, is situated on the east side of Falmouth harbour; one mile distant from Falmouth, and 270 from London. It consists only of one street, containing about twenty houses, inhabited chiefly by fishermen. A fair is held annually, but the town has never been incorporated, and has neither church, chapel, nor meeting-house; yet it sends two representatives to parliament, and has done so ever since the fourth year of queen Elizabeth. It is governed by a portreeve, who has the title of mayor. The principal influence and property of the borough are now possessed by the marquis of Buckingham. King Henry VIII. erected a castle here, opposite to that of Pendennis, to which it is very inferior both in size and situation, though built nearly at the same time, by the same monarch, and for the same purpose, *i. e.* the security of Falmouth harbour. The works are completely commanded by a hill, which rises immediately behind them. Beauties of England and Wales, vol. ii.

MAXANTELLA, an island near the port of Matanchel, on the west coast of New Mexico, in the North Pacific ocean.

MAXDORF, a town of Bohemia, in the circle of Leitmeritz; 10 miles W. of Kamnitz.

MAXEN, a town of Saxony, famous for a victory obtained by the Austrians, commanded by count Daun, over the Prussians, in 1759, when 20,000 Prussians laid down their arms and surrendered prisoners of war; 80 miles S. of Dresden.

MAXENTIUS, MARCUS AURELIUS VALERIUS, in *Biography*, a Roman emperor, was the son of Maximian, and married the daughter of Galerius. The abdication of Maximian and Dioclesian, in 305, made room for the elevation of Galerius and Constantius to the rank of Augustus: of course, two new Cæsars were to be appointed; but Maxentius, on account of his vicious propensities, was passed over, though, from his birth and rank in the state, he seemed best entitled to that honour. Deprived of what he thought was his natural right, he waited only for an opportunity of asserting his claims; and in 306 he declared himself independent emperor, and, without remorse or compunction, put to death the prefect, and other magistrates who adhered to Galerius. His abdicated father, by this time, weary of retirement, resuming his dignity, joined him; and Severus, the newly-made Cæsar, who marched against them, finding himself deserted by his army, surrendered himself prisoner to the victorious emperors. He was at first received with great humanity, and treated with a respect due to his rank. Maximian himself conducted the captive emperor to Rome, and gave him the most solemn assurances that he had secured his life and happiness, by the resignation of the purple. But, in spite of the honour of an emperor, Severus could only obtain an easy death, and an imperial funeral. In February 307, the sentence was signified to him, but the manner of executing it was left to his own choice. He preferred the favourite mode of the ancients, that of opening his veins; and as soon as he expired, his body was carried to the sepulchre which had been constructed for the family of Gallienus. Galerius, at this time, entered Italy with a powerful army, for the purpose of dethroning Maxentius; but he found the new emperor so strongly defended, and his own troops so wavering in their fidelity, that he thought it best to consult his safety by a retreat. Maximian also became his rival, and attempted to depose him; but the soldiers decided in favour of the younger claimant, and Maximian, who aimed at all, lost all, and was obliged to retire with shame and humiliation. Maxentius was now the undisputed master of Italy. He passed into Africa, where he rendered himself odious by his cruelty and oppressions. His suspicions frequently endangered the lives of persons of rank; and the honour and chastity of their wives and daughters were daily exposed to violation from his brutal desires. The heroic conduct of a Christian lady, who plunged a dagger into her breast, in order that she might escape his impure embraces, has been recorded by some writers to her honour, though others have questioned the lawfulness of the act; but none have hesitated to hold up the conduct of the tyrant to that contempt and infamy which it so justly merited. Upon the return of Maxentius

Maxentius to Rome, he was informed that Conſtantine was come to dethrone him. The reſources of Maxentius, both in men and money, were ſtill conſiderable. The Prætorian guards felt how ſtrongly their own intereſt and ſafety were connected with his cauſe, and an army was ſpeedily collected. It was far from the intention of the emperor to lead his troops in perſon. "A ſtranger," ſays the hiſtorian, "to the exerciſes of war, he trembled at the apprehenſion of ſo dangerous a conteſt; and as fear is commonly ſuperſtitious, he liſtened with melancholy attention to the rumours of omens and preſages, which ſeemed to menace his life and empire. Shame at length ſupplied the place of courage, and forced him to take the field, being unable to ſuſtain the contempt of the Roman people. The circus reſounded with their indignant clamours, and they tumultuouſly beſieged the gates of the palace, reproaching the puſillanimity of their indolent ſovereign, and celebrating the heroic ſpirit of Conſtantine. Before Maxentius left Rome, he conſulted the Sibylline books. The guardians of thoſe ſacred oracles were as well verſed in the arts of this world, as they were ignorant of the ſecrets of fate; and they returned him a very prudent anſwer, which might adapt itſelf to the event, and ſecure their reputation, whatever ſhould be the chance of arms." At length he aſſembled his forces, and gave his enemy battle; but loſt the day, and fled with the utmoſt precipitation to the city. The bridge, over which he was to croſs the Tiber, was in a decayed ſituation, and he fell into the river, and was drowned. This happened on the 24th of September, A.D. 312. The cowardice and luxuries of Maxentius were as conſpicuous as his cruelties. He oppreſſed his ſubjects with heavy taxes, to gratify the cravings of his pleaſure, or the avarice of his favourites; and he was ſo debauched in his manners, that neither virtue nor innocence was ſafe, if within his reach. He was naturally deformed, of an unwieldy body, and the ſmalleſt exertions to him were as Herculean labours. Gibbon, vol. ii. 8vo. Univer. Hiſt.

MAXILLA, in *Anatomy*, the jaw. The term is uſually applied to the bones. The maxilla ſuperior contains ſix pairs of bones, and one ſingle bone; the maxilla inferior is a ſingle bone. See CRANIUM.

MAXILLA, *Fractures* and *Diſlocations of*, in *Surgery*. See FRACTURE and LUXATION.

MAXILLARIS, MAXILLARY, in *Anatomy*, an epithet applied to various parts about the jaws. There is an external, an internal, and an inferior maxillary artery (ſee ARTERY); one inferior and two ſuperior maxillary bones (ſee CRANIUM); a maxillary gland, which is a mucous gland of the cheek, placed near the back upper teeth; a ſuperior and inferior maxillary nerve, branches of the fifth pair (ſee NERVE); a maxillary ſinus or antrum maxillare, which is a large hollow of the ſuperior maxillary bone. See CRANIUM and NOSE.

MAXILLARY SINUS, *Abſceſs of*, in *Surgery*. See ABSCESS.

MAXILLARY *Sinus*, *Fungus of*. See FUNGUS.

MAXIM denotes an eſtabliſhed propoſition or principle; in which ſenſe it amounts to much the ſame with axiom.

Maxims are a kind of propoſitions, which have paſſed for principles of ſcience; and which, being ſelf-evident, have been by ſome ſuppoſed innate.

A maxim in law is ſaid to be a propoſition, of all men confeſſed and granted without argument or diſcourſe.

Maxims of the law are holden for law; and all other caſes that may be applied to them, ſhall be taken for granted. (1 Inſt. 11. 67. 4 Rep.) The maxims in our law-books, which are many and various, are ſuch as the following, *viz.* It is a maxim, that land ſhall deſcend from the father to the ſon, &c. That if a man have two ſons, by divers venters, and the one purchaſe lands and die without iſſue, the other ſhall never be his heir, &c. That as no eſtate can be veſted in the king, without matter of record, ſo none can be diveſted out of him but by matter of record. That an obligation, or matter in writing, cannot be diſſolved by an agreement by word, without writing. Co. Litt. 11. 141. See LAW.

MAXIMA CÆSARIENSIS, in *Ancient Geography*, one of the five provinces into which Britain was divided by the Romans; but the reaſon of the name, and the time when this province was erected, are not certainly known. It was bounded on the ſouth by the Humber, on the eaſt by the German ocean, on the weſt by the Iriſh ſea, and on the north by the wall of Severus; and contained the countries of the Pariſi and the Brigantes, which are now the counties of York, Durham, Lancaſter, Cumberland, and Northumberland. For the other four provinces, ſee FLAVIA *Cæſarienſis* and VALENTIA.

MAXIMA, *Lat.*, *Maxime*, *Fr.* See MASSIMA and TIME-*Table*.

MAXIMA *et Minima*, in *Analyſis and Geometry*, are the greateſt and leaſt values of a variable quantity; and the method of finding theſe greateſt and leaſt values is called the *method de maximis et minimis*, which forms one of the moſt intereſting inquiries in the modern analyſis. This ſubject was conſidered geometrically by ſome of the moſt ancient mathematicians, particularly by Apollonius, in the fifth book of his Conics; and there are ſtill a few problems of this kind, which ſucceed better by the geometrical than by the analytical method: their number, however, is very limited, compared with thoſe which may be elegantly performed by analyſis. To the latter, therefore, we ſhall principally direct our attention, only ſhewing, in a few caſes, how the ſame may be accompliſhed by means of the pure elements of geometry.

The method de maximis et minimis, according to the analytical doctrine, firſt aroſe at the beginning of the ſeventeenth century, after the invention of Deſcartes for expreſſing the properties of curve lines by means of algebraical equations, and claſſing them into different orders, according to the degree of the equation which expreſſed the relation between the abſciſs and ordinate. Beſides the method of Deſcartes, we have alſo thoſe of Fermat, Hudde, Huygens, Sluſe, and ſome others, which are now all ſupplanted by the general and elegant method of fluxions; yet as theſe ſeveral methods may be conſidered as ſo many ſteps towards the diſcovery of the latter, it will be intereſting to have a brief abſtract of them, in order to ſhew how ſlow and progreſſive are the ſteps to knowledge, and by what imperceptible degrees we arrive towards perfection.

Fermat's Method de Maximis et Minimis.—The principle upon which Fermat formed his operation conſiſted in this: that when the ordinate of a curve was the greateſt poſſible, if we augmented the variable quantity x, which repreſents the abſciſs, by an indefinitely ſmall quantity e, the ordinate correſponding to this abſciſs will be equal to the former, or will approach towards equality indefinitely near; or, which is the ſame, the increaſe or decreaſe of an ordinate, when it approaches indefinitely near its maximum or minimum, is nothing; and, therefore, theſe two ordinates may be conſidered as equal, whence an equation is obtained, from which cancelling the like quantities, and all thoſe powers of e beyond the firſt, becauſe they are indefinitely ſmall with regard to the others, and dividing the other terms by e, the value

value of x will be obtained, that renders the function a maximum or a minimum.

For example: let it be propofed to find that value of x, in the equation $y^2 = 2ax - x^2$, which renders y a maximum.

Increafe the variable quantity by e; then,

$$y^2 = 2a(x+e) - (x+e)^2,$$

$$\text{or, } 2ax - x^2 = 2ax - x^2 + 2ae - 2ex + e^2,$$

$$\text{or, } 0 = 2ae - 2ex;$$

by rejecting e^2, which is indefinitely fmall: whence again,

$$2ae = 2ex, \text{ or } x = a.$$

Again: required the value of x, in the equation $y^3 = ax^2 - x^3$, which renders the whole function a maximum.

Making, as before, $x = x + e$, we have

$$ax^2 - x^3 = ax^2 - x^3 + 2axe + ae^2 - 3ex^2 - 3e^2x - e^3,$$

$$\text{or, } 0 = +2axe - 3ex^2;$$

by fuppreffing thofe powers of e above the firft: whence,

$$3ex^2 = 2axe, \text{ or } x = \tfrac{2}{3}a.$$

Thefe examples will be fufficient to fhew the fpirit of Fermat's rule, which is in principle much the fame as the fluxional method; only that it wants that generality and elegance which conftitute the diftinguifhing characteriftics of the latter.

Defcartes' Method.—This confifted in making two of the roots of the equation equal to each other; in which cafe, two of the ordinates of the curve became equal, and thus indicated the maximum or minimum ftate. This, however, being much lefs eligible than the preceding, we will not enter into farther explanation, but proceed to Hudde's method, which is in principle the fame as Defcartes's, but more elegant and concife.

Hudde's Method.—This, as we have obferved, confifted, like that of Defcartes, in making two of the roots of the propofed equation equal to each other, and for which he gave the following rule: *viz*, multiply each term of the equation, arranged according to the power of x, by the terms of an arithmetical progreffion, *viz*. the firft by the firft, the fecond by the fecond, &c.; and the equation thus obtained will indicate the maximum or minimum required.

Let us take, for example, the equation above, $ax^2 - x^3 = y^3$.

Arranging this equation according to the powers of x, and fupplying the deficient term, we have

$$\begin{array}{ll} & x^3 - ax^2 \pm 0x - y^3 = 0. \\ \text{Arith. prog.} & \underline{3, \quad 2, \quad 1, \quad 0.} \\ & 3x^3 - 2ax^2 = 0 \\ & 3x^2 = 2ax^2, \text{ or } x = \tfrac{2}{3}a, \text{ as above.} \end{array}$$

Again: let $x^2 - ax + y^2 - 2by + b^2$, be propofed.

$$\begin{array}{ll} \text{Writing this,} & x^2 - ax + (y^2 - 2by + b^2) = 0. \\ \text{Arith. prog.} & \underline{2, \quad 1, \quad 0.} \\ & 2x^2 - ax = 0, \text{ or } x = \tfrac{1}{2}a. \end{array}$$

This rule, though not fo general as could be wifhed, is ftill extremely fimple and ingenious; and, confidering the ftate of analyfis at the period it was difcovered, it is highly creditable to its author, to whom we are alfo indebted for feveral other analytical and geometrical improvements.

Huygens' Method.—As the rule of Hudde, defcribed above, was a fimplification of that of Defcartes, fo the following one is founded on the principle of Fermat, and can only be confidered as a fimplification of his method. Inftead of fubftituting $x + e$ for x, and then cancelling the like terms, fuppreffing thofe in which e rifes to a higher power than the firft, and finally dividing by e; Huygens, as alfo Slufe, arrive at the final equation at once by the following fimple rule: multiply each of the terms in which x is found by its exponent, rejecting all thofe into which it does not enter; divide the refult by x, and make the whole equal to zero; and the equation thus arifing will give the value of x required.

For example: required the value of x in the equation $3ax^2 - x^3 = y^3$.

Multiplying each of thofe terms by the exponent of x in them, we have $6ax^2 - 3x^3$; then dividing by x,

$$6ax^2 - 3x^2 = 0, \text{ or } 3x^2 - 6ax = 0,$$

$$\text{or, } x^2 - 2ax + a^2 = a^2, \text{ or } x = a \pm a;$$

that is, $x = 0$, or $2a$.

This rule differs in no refpect from our fluxional operation, except that we divide by $\dot{x}$ inftead of x; yet the generality of the latter is fuch, that the rules above defcribed have long been forgotten, and are only given here as prefenting an hiftorical view of the methods employed by our predeceffors; and in this refpect they are entitled to particular notice; for in them is evidently contained the germ of the modern analyfis. Farther advances were made in thefe kinds of operations in the method of tangents, but they are foreign to our prefent enquiry; of thefe the *differential triangle* of Barrow is particularly interefting. See TANGENTS.

Of the method de maximis et minimis according to the fluxional or differential calculus.

1. The fluxion of a quantity, when it is a maximum or a minimum, is equal to zero, or 0. This is obvious from the definition of a fluxion, for this being the meafures or rates of increafe or decreafe of a variable quantity; when this quantity becomes a maximum, or a minimum, its fluxion muft be $= 0$, becaufe at that point it admits of no farther increafe or decreafe.

2. If a quantity be a maximum or minimum, any power or root of that quantity muft then evidently be a maximum or minimum. For the power or root of a quantity will increafe or decreafe as long as the quantity itfelf increafes or decreafes, and no longer.

3. Any conftant multiple, or part, of a quantity, which is a maximum or a minimum, muft alfo be a maximum or a minimum. For the multiple or part of a quantity will increafe or decreafe as long as the quantity itfelf increafes or decreafes, and no longer; therefore, when its fluxion is made equal to zero, the conftant multiplier may be neglected.

4. The fluxion of a conftant quantity $= 0$. For this admitting of no increafe or decreafe has no fluxion, or its fluxion $= 0$.

1. To divide a given number (a) into two fuch parts x and y, that $x^m y^n$ may be a maximum.

Since $x + y = a$, and $x^m y^n =$ a maximum, the fluxions of each $= 0$; the former becaufe it is conftant, and the latter becaufe it is a maximum, whence

$$\dot{x} + \dot{y} = 0$$
$$m y^n x^{m-1} \dot{x} + n x^m y^{n-1} \dot{y} = 0:$$

from the firft we have $\dot{x} = -\dot{y}$; and fubftituting this in the fecond, gives

$$m y^n x^{m-1} \dot{x} - n x^m y^{n-1} \dot{x} = 0, \text{ or}$$
$$m y^n x^{m-1} = n x^m y^{n-1}, \text{ or}$$
$$m y = n x; \text{ whence}$$

$y =$

$$y = \frac{n}{m} x$$

Consequently, $x + \frac{n}{m} x = a$, or

$$x = \frac{m a}{m + n}, \text{ and } y = \frac{n a}{m + n}.$$

If $m = n$, then the two parts are equal.

Hence, to divide a quantity (a) into three parts, x, y, z, so that $x y z$ may be a maximum, the three parts must be all equal amongst themselves. For whatever one of the parts may be, if it be constant, the product of the other two will be the greatest when they are equal to each other; and in the same manner, if we consider any one of the parts as constant, the rectangle of the other two will be the greatest when they are equal to each other; whence it is obvious, that the product will be the greatest when the three parts are equal to each other. And in the same manner, if the given quantity be divided into any number of parts, the product of them, or the product of any equal powers of them, will be the greatest when the several parts are all equal amongst themselves.

2. To divide a given number (a) into two such parts, x and y, that the sum of their alternate quotients may be a maximum.

Here we must have $x + y = a$,

$$\text{and } \frac{x}{y} + \frac{y}{x} = \text{a maximum.}$$

Now since the first is constant, and the latter a maximum, we have $\dot{x} = -\dot{y}$, and

$$\frac{\dot{x} y - \dot{y} x}{y^2} + \frac{\dot{y} x - \dot{x} y}{x^2} = 0;$$

or, substituting for $\dot{x}$ its equal $-\dot{y}$, this becomes

$$-\frac{y \dot{y} + x \dot{y}}{y^2} + \frac{x \dot{y} + y \dot{y}}{x^2} = 0, \text{ or}$$

$$\frac{x \dot{y} + y \dot{y}}{x^2} = \frac{y \dot{y} + x \dot{y}}{y^2};$$

whence we have $\frac{1}{x^2} = \frac{1}{y^2}$, or $y^2 = x^2$, or $x = y$; that is, each of the required quantities is equal to $\frac{1}{2} a$.

3. Of all right-angled triangles, having the same hypothenuse; to determine that which shall have the greatest area.

Let the given hypothenuse be represented by h, and the required sides by x and y; then we have these two equations;

$$x^2 + y^2 = h^2$$
$$x y = \text{a maximum.}$$

In the first we have $2 x \dot{x} + 2 y \dot{y} = 0$, or $\dot{x} = -\frac{y \dot{y}}{x}$; in the second $\dot{x} y + \dot{y} x = 0$.

Substitute for $\dot{x}$, and we obtain

$$-\frac{y^2 \dot{y}}{x} + \dot{y} x = 0, \text{ or } y^2 = x^2, \text{ or } y = x;$$

and, consequently, both x and $y = \frac{a \sqrt{2}}{2}$.

This result is also readily obtained from the pure elements of geometry; for the hypothenuse being given, let there be described upon it a semicircle; then it is obvious, that the area of that triangle will be the greatest whose perpendicular, let fall upon the hypothenuse from the right angle, is the greatest; and this evidently is the case when that perpendicular is equal to the radius, or when the right-angled triangle is also isosceles.

4. To find the greatest cylinder that can be inscribed in a given cone.

Let the altitude of the cone be represented by a, the diameter of its base by b, the altitude of the cylinder by x, and the diameter of its base by y: also put $.7854 = p$.

Now by similar triangles, as

$$a : b :: b - x : \frac{b}{a}(b - x) = y;$$

and by the question $p y^2 x =$ a maximum, or substituting for y, and suppressing $\frac{b^2 p}{a^2}$, because it is a constant multiplier, we have

$$b^2 x - 2 b x^2 + x^3 = \text{a maximum, or}$$
$$b^2 \dot{x} - 4 b x \dot{x} + 3 x^2 \dot{x} = 0; \text{ whence}$$
$$3 x^2 - 4 b x = -b^2,$$

which reduced, gives $x = \frac{1}{3} b$.

5. To divide a given arc A into two parts such, that the mth power of the sine of one part, into the nth power of the sine of the other, may be a maximum.

Let P and Q represent the two arcs, x and y their sines, radius being unity, then we must have

$$x^m \times y^n = \text{a maximum,}$$

and consequently, $m y^n x^{m-1} \dot{x} + n x^m y^{n-1} \dot{y} = 0$; whence we find $m y \dot{x} = -n x \dot{y}$.

$$\text{Now } \dot{P} = \frac{\dot{x}}{\sqrt{(1 - x^2)}}, \text{ and } \dot{Q} = \frac{\dot{y}}{\sqrt{(1 - y^2)}}$$

from the known doctrine of fluxions; also

$\dot{P} + \dot{Q} = 0$, because $P + Q = A$, whence $\dot{P} = -\dot{Q}$;

$$\text{or, } \frac{\dot{y}}{\sqrt{(1 - y^2)}} = \frac{-\dot{x}}{\sqrt{(1 - x^2)}}.$$

Multiply this equation by the equation

$$m y \dot{x} = -n x \dot{y},$$

and we obtain

$$m \times \frac{y}{\sqrt{(1 - y^2)}} = n \times \frac{x}{\sqrt{(1 - x^2)}}$$

or, which is the same,

$m \,.\, \tan.\ P = n \,.\, \tan.\ Q$,

whence

$m : n ::$ tan. Q : tan. P

$(m + n) : (m - n) ::$ (tan. Q + tan. P) : (tan. Q − tan. P)

But

(tan. Q + tan. P) : (tan. Q − tan. P) :: sin. (Q + P) : sin. (Q − P);

or, $(m + n) : (m - n) ::$ sin. A : sin. (Q − P);

whence, sin. (Q − P) = sin. A $\times \frac{m - n}{m + n}$.

Now, therefore, knowing the sine of the difference, we know also the difference of the arcs, whence the sum being also given, the arcs themselves are readily determined. We might have obtained the same result from the known trigonometrical formula; *viz.*

sin. (P + Q) = sin. P . cos. Q + sin. Q . cos. P,

that is, the above notation remaining, and making

sin. (P + Q), or sin. A $= a$.

$x \sqrt{}$

$$x\sqrt{(1-y^2)} + y\sqrt{(1-x^2)} = a,$$

and we have also $x^m y^n$ = a maximum: from which two equations the values of x and y may be determined; and, consequently, the arcs of which they are the sines.

6. To find the value of x in the equation x^x = a minimum. Make $x^x = z$, then x log. x = log. z, and

$$\dot{x}\log. x + x \times \frac{\dot{x}}{x} = \frac{\dot{z}}{z} = 0,$$

because, x^x, or z, is to be a minimum,

whence $\log. x = -1$,

that is, x is that number of which the hyperbolic logarithm is -1.

Application of Maxima et Minima to physical Problems.

7. Given two elastic bodies A and C to find an intermediate body x, so that the motion communicated from A to C, through x, may be a maximum.

Put a = the given velocity of A, w the velocity communicated to C, and z the velocity communicated to x; then by the known theory of elastic bodies

$$A + x : 2A :: a : w$$
$$x + C : 2x :: w : z$$

taking the product of corresponding terms

$$(Ax + x^2 + AC + Cx) : 4Ax :: a : z, \text{ or}$$

$$A + x + \frac{AC}{x} + C : 4A :: a : z$$

Now as the two mean terms are constant, the last term varies inversely as the first; and, therefore, as the last is to be a maximum, the first term must be a minimum; and, consequently, its fluxion = 0; that is,

$$\dot{x} - \frac{AC\dot{x}}{x^2} = 0; \text{ whence } x = \sqrt{AC};$$

that is, x must be a mean proportional between the two given bodies.

8. To determine at what angle the wind ought to strike against the sails of a windmill, so that the effect to put it in motion may be the greatest possible.

Let x = the cosine of the required angle, then the $\sin.^2 = 1 - x^2$, radius being unity; hence by the principles of hydrostatics, the effect being as the product of the cosine into the square of the sine, we must have

$$x \times (1 - x^2) = x - x^3 = \text{a maximum},$$

whence $\dot{x} - 3x^2\dot{x} = 0$, or $x = \sqrt{\tfrac{1}{3}} = \text{cos. } 54^\circ\ 44'$,

which is the required angle.

9. Given the solidity of a cone to find the base and height, when the time of its vibration shall be a minimum, the point of suspension being at the vertex.

Let x = the radius of the base, y = the altitude, p = 3.1416; then $\frac{1}{3}pxy^2 = s$, the given solidity.

Now the distance of the point of suspension from the centre of oscillation, in a cone suspended at its vertex, $= \frac{4x^2 + y^2}{5x}$. See OSCILLATION. And this, from the nature of the problem, must be a minimum.

But $y^2 = \frac{3s}{px}$, whence $\frac{4x^2 + y^2}{5x} = \frac{4px^3 + 3s}{5px^2}$.

This being put into fluxions gives

$$\frac{60p^2x^4\dot{x} - 40p^2x^4\dot{x} - 30psx\dot{x}}{25p^2x^4} = 0,$$

or, $6px^3 - 4px^3 - 3s = 0$,

whence $x = \sqrt[3]{\frac{3s}{2p}}$, and $y = \sqrt{2} \times \sqrt[3]{\frac{3s}{2p}}$,

consequently, $x : y :: 1 : \sqrt{2}$.

10. To find the position of the planet Venus, when it gives the greatest quantity of light to the earth

Let S be the sun, (*fig.* 1. *Plate* XIII. *Analysis*,) E, the earth, V, Venus, produce E V, on which let fall the perpendicular S B, and with the centre V, and distance V S, describe the circular arc S A. Put S E = a, S V = A V = b, E V = x, B V = y; then A B = $b - y$, the versed sine of the angle S V A; and by the known astronomical theory, the quantity of light received by the earth from Venus varies as $\frac{b-y}{x^2} = \frac{b}{x^2} - \frac{y}{x^2}$ = a maximum.

Again, (Euclid, b. ii. p. 12.) $a^2 = b^2 + x^2 + 2xy$; therefore, $y = \frac{a^2 - b^2 - x^2}{2x} = \frac{m^2 - x^2}{2x}$ (by making $m^2 = a^2 - b^2$).

Hence, the quantity of light varies as

$$\frac{b}{x^2} - \frac{m^2 - x^2}{2x^3} = \frac{2bx - m^2 + x^2}{2x^3} = \text{a maximum};$$

hence its fluxion

$$\frac{(2b\dot{x} + 2x\dot{x})\,2x^3 - 6x^2\dot{x}\,(2bx - m^2 + x^2)}{4x^6} = 0,$$

or, $(2b + 2x)\,2x^3 - 6x^2(2bx - m^2 + x^2) = 0$,

whence by reduction, &c.

$$-x^2 - 4bx + 3m^2 = 0,$$

therefore, $x^2 + 4bx = 3m^2$,

and hence, $x = -2b \pm \sqrt{(4b^2 + 3m^2)}$

Since then, we know the three sides of the triangle E S V, the angle E of elongation is readily found = $39^\circ\ 44'$.

We might have extended these kinds of problems to a much greater length, had the limits of our article admitted of it; but it is presumed that the above will throw considerable light on the subject; and render the application of these principles easy and familiar in most other cases. The reader who is desirous of farther information relating to the method of maxima et minima, as applicable to mechanical and astronomical subjects, may consult Dealtry's Principles of Fluxions, or Vince's Treatise on the same subject: see also Simpson's and Maclaurin's Treatises on Fluxions, to the former of which works we are indebted for the following article.

Application of Maxima et Minima to curve Lines.—Having already considered this subject at considerable length under the article ISOPERIMETRICAL *Problems*, we shall, therefore, be very brief in our observations with regard to them in this place; but as there are certain problems of this kind, which easily yield to the ordinary method of maxima et minima, we thought it right to touch slightly on this subject in the present article.

To find the nature of curves, in which some conditions being invariable, others become the greatest or the least possible.

1. Given the length of a curve to find the area a maximum.

It is evident, that by merely putting the fluent $y\dot{x}$ a maximum,

maximum, no solution can be obtained; for no limitation is expressed, and the fluent will admit of increase or decrease without limit. But as the length is given, the $f.\dot{z}$, so far as concerns the $f y \dot{x}$, is a given quantity; therefore, the

$$f.y\dot{x} \pm f.\dot{z} \text{ must be a maximum:}$$

or, rendering the terms homogeneous, in order that they may admit of comparison,

$$f.y\dot{x} \pm f.a\dot{z} = \text{a maximum.}$$

Now if for every individual value of y, this flowing quantity be always a maximum, the whole fluent will be so likewise; but for every such value of y, the flowing quantity is $y\dot{x} \pm a\dot{z}$. Hence the nature of the curve will be determined by ascertaining what relations of $\dot{x}$ and $\dot{z}$ will render $y\dot{x} \pm a\dot{z}$ a maximum for any given value of y; or the fluxion of $y\dot{x} \pm a\dot{z} = 0$, whilst y is constant; and this must be the case for every successive value of y throughout; so that in each limiting portion of the area, for every value of y, the ratio of $\dot{x}:\dot{z}$ must be such as to make $y\dot{x} \pm a\dot{z}$ a maximum,

therefore $\quad y\ddot{x} \pm a\ddot{z} = 0$; but $\dot{z}^2 = \dot{y}^2 + \dot{x}^2$;

whence $\quad \dot{z}\ddot{z} = \dot{x}\ddot{x}$, and $\ddot{z} = \dfrac{\dot{x}\ddot{x}}{\dot{z}}$;

consequently, $\quad y\ddot{x} = \mp\dfrac{a\dot{x}\ddot{x}}{\dot{z}}$, and $y\dot{z} = \mp a\dot{x}$.

But from the nature of the problem $y\dot{z}$ must be positive, and, therefore, the true result is $y\dot{z} = a\dot{x}$.

Now, in the circle $a : y :: \dot{z} : \dot{x}$; whence $a\dot{x} = y\dot{z}$. Hence the curve required is a circle; in which the length being given, the area is a maximum.

Therefore, if A and B denote any functions of x and y, and $\dot{x} = \sqrt{(c^2 + \dot{y}^2)}$, where c is constant, the expression $A\dot{x} \mp B\dot{y}$ is a maximum, or a minimum, when $A\dot{y} = \mp B\dot{x}$, or the functions of x and y are reciprocal.

2. To determine the nature of a curve, which generates a surface, so that the surface being given, the solid may be a maximum.

Here $f.2py\dot{z}$, or $f.y\dot{z}$ is given; and $f.y^2\dot{x}$ is a maximum: hence the fluent of $ay\dot{z} \pm$ fluent of $y^2\dot{x}$ a maximum;

or, $\quad f.ay\dot{z} \pm f.y^2\dot{x} = \text{a maximum};$

therefore, $\quad ay\dot{x} = y^2\dot{z}$, or $a\dot{x} = y\dot{z}$,

which is a property of the circle, and the body is a sphere.

3. To determine the nature of the generating curve, that the solidity being given, the surface may be a minimum.

Here $f.y^2\dot{x}$ is given, and $f.ay\dot{z}$ is a minimum; therefore, $y^2\dot{z} = ay\dot{x}$, and $y\dot{z} = a\dot{x}$: the required curve, therefore, is a circle, and the body a sphere.

The same principles are employed in the work above quoted, to the finding of the solid of least resistance, and a few other problems of the same kind; but as we have already considered these under a more general form in the article Isoperimetry, we shall not pursue the subject any farther in this place.

To ascertain the number of maxima or minima that appertain to any variable function.

In the preceding problems it has generally happened, that the equations from which we have derived our maximum or minimum have been of the first degree; and, therefore, admitted of only one rational value; but it may happen that the final equation is of a higher dimension, and, consequently, admitting of several roots, each of which may be employed, at least so far as we have considered the subject at present: also, as our operation is precisely the same, whether we are seeking a maximum or a minimum, it is necessary to have some means of determining, *à priori*, which root gives the maximum, and which the minimum, as well as to ascertain the number of each.

In our former definition, we stated a maximum, or minimum, to be the greatest or least state of a variable function; which was done in order to simplify the idea, being in fact the real import of the word; and in any question of a physical nature, the term must be still understood in this light. That is, if the fluxional equation be of such a degree as to admit of several roots, that one must be found which makes the result the greatest, or least possible; but analytically, we must understand this term to signify that state of a variable function, which, if the variable upon which it depends be either increased or decreased, the whole function will decrease or increase, according as it is in its maximum or minimum state; but this increase or decrease is frequently limited, and being carried beyond a certain point, the whole function will again increase or decrease. This will be more obvious, from (*fig.* 2. *Plate* XIII. *Analysis.*) where the several ordinates A B, E F, I K, are maxima, and C D, G H, are minima, any one of which, as for example E F, will be observed to recede from its maximum towards a minimum, as it approaches towards C or D; but beyond those points, it again approaches towards its other maximum value. The object, therefore, of our present enquiry, is to ascertain the number of maxima or minima that a function may have, and which root of the final equation gives the one, and which the other.

In order to this, let y be any function of x, and suppose that x has attained that particular value which renders the function y a maximum or a minimum; it follows then, if x be either increased or diminished by any quantity h, that we ought to obtain for the whole function a result less or greater than the preceding, according as it was in its maximum or minimum state. Now, if we represent by y'' the function answering to $x + h$, and by y' the function answering to $x - h$, we shall have from Taylor's theorem

$$y' = y - \frac{h\dot{y}}{1.\dot{x}} + \frac{h^2\ddot{y}}{1.2\dot{x}^2} - \frac{h^3\dddot{y}}{1.2.3\dot{x}^3} + \&c.$$

$$y'' = y + \frac{h\dot{y}}{1.\dot{x}} + \frac{h^2\ddot{y}}{1.2\dot{x}^2} + \frac{h^3\dddot{y}}{1.2.3\dot{x}^3} + \&c.$$

And since the powers of a quantity which is less than unity become less and less as the exponent is greater, it may be readily conceived, that h may be taken so small, that each of the terms of the preceding series may be greater than the sum of all the following ones; and, consequently, the sign of the whole series, beginning at any term, will always be the same as that of the first term, as to positive or negative.

Therefore, if $\dfrac{h\dot{y}}{\dot{x}}$ be any thing but zero, y will be greater than y', and less than y''; and, consequently, is neither a maximum nor minimum; therefore, when it is either the one or the other, $\dfrac{h\dot{y}}{\dot{x}} = 0$. In this case, we have

$$y' = y + \frac{h^2\ddot{y}}{1.2\dot{x}^2} - \frac{h^3\dddot{y}}{1.2.3\dot{x}^3} + \&c.$$

$$y'' = y + \frac{h^2\ddot{y}}{1.2\dot{x}^2} + \frac{h^3\dddot{y}}{1.2.3\dot{x}^3} + \&c.$$

where it is obvious that $y > y'$, and $> y''$; or $y < y'$, $< y''$, according as $\dfrac{h^2\ddot{y}}{1.2\dot{x}^2}$ is negative or positive; and

is,

is, therefore, neceffarily a maximum or a minimum.

But if $\frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2} = 0$, then again y is neither a maximum nor a minimum; for in this cafe, y is $> y'$, and $< y''$. We have, therefore, the following rule for afcertaining the maxima et minima of any propofed function. Find the value of x in the equation $\frac{\dot{y}}{\dot{x}} = 0$, and fubftitute it for x in the expreffion $\frac{\ddot{y}}{\dot{x}^2}$; then if the refult is negative, y is a maximum, if pofitive, a minimum; and if it be zero, then y is neither a maximum nor a minimum, unlefs alfo $\frac{\dddot{y}}{\dot{x}^3}$ be equal to zero; and then it will depend upon the fign of $\frac{\ddddot{y}}{\dot{x}^4}$; and fo on, and the fame procefs being obferved, with regard to each of the roots of the fluxional equation, the number of maxima et minima will be obtained.

Let us illuftrate the preceding rule by an example.

1. Find $y = x^4 - 8x^3 + 22x^2 - 24x + 10$, a maximum or minimum. Here

$$\frac{\dot{y}}{\dot{x}} = 4x^3 - 24x^2 + 44x - 24 = 0;$$

where $x = 1, 2$, and 3.

And it is required to find which of thefe roots anfwers to the maxima, and which to the minima. Now

$$\frac{\ddot{y}}{\dot{x}^2} = 12x^2 - 48x + 44.$$

And here, making $x = 1, 2, 3$, the refults are refpectively $+, -, +$; therefore the root 2 anfwers to the maximum, and the other two to the minima.

2. Let there now be propofed the function

$$y = x^5 - 7x^4 + 19x^3 - 25x^2 + 16x + 10.$$

Here $\frac{\dot{y}}{\dot{x}} = 5x^4 - 28x^3 + 57x^2 - 50x + 16 = 0$.

And the roots of this equation are $1, 1, 2, 1\frac{3}{5}$. Now

$$\frac{\ddot{y}}{\dot{x}^2} = 20x^3 - 84x^2 + 114x - 50,$$

which $= 0$, when $x = 1$; therefore the root 1 gives neither a maximum nor a minimum, unlefs $\frac{\dddot{y}}{\dot{x}^3} = 0$; which upon trial does not obtain.

But by affuming $x = 2$ in this equation, the refult is -4; and, confequently, this value of x anfwers to a maximum.

And by fubmitting the other root $1\frac{3}{5}$ to the fame teft, a fimilar refult will be obtained.

We will add another example, with which we muft conclude this article.

3. To find when the function

$$y = x^3 - 18x^2 + 96x - 20$$

becomes a maximum or a minimum.

Here $\frac{\dot{y}}{\dot{x}} = 3x^2 - 36x + 96 = 0$,

in which equation the roots are $x = 4$, $x = 8$.

Now $\frac{\ddot{y}}{\dot{x}^2} = 6x - 36$.

Here the root 8 gives $\frac{\ddot{y}}{\dot{x}^2}$ *pofitive.*

And the root 4 gives $\frac{\ddot{y}}{\dot{x}^2}$ *negative.*

Therefore the former anfwers to the minimum, and the latter to the maximum.

If the fluxional equation has no real root, then it follows that the propofed function admits of neither a maximum nor a minimum; but increafes or decreafes *ad infinitum.*

MAXIMENE, in *Geography*, a town of Walachia; 18 miles N. of Galacz.

MAXIMIANOPOLI, a town of European Turkey, in Romania, founded by the emperor Maximian; formerly the fee of a bifhop, in the province of Rhodope, but now a fmall place 60 miles S.W. of Adrianople.

MAXIMIANOPOLIS, in *Ancient Geography*, a town of Paleftine, the fame as Hadad-Rimmon, in the valley of Jezreel, and in the plain of Megiddo. An ancient traveller places it 17 miles from Cæfarea, and 10 from Jezreel.—Alfo, a town of Thrace, in Media, upon the northern bank of the Marfh Buton; called alfo Myxæ. See MAXIMIANOPOLI.

MAXIMIANUS, HERCULIUS MARCUS AURELIUS VALERIUS, in *Biography*, a native of Sirmium, in Pannonia, was the fon of parents who gained their daily fubfiftence by the labour of their hands. Brought up in ruftic manners, and deftitute of every advantage of education, he early embraced that way of life which alone prefented the profpect of advancement, and enlifted as a common foldier in the Roman armies. Afpiring to fomething better than the fervile character which he then held, he gradually rofe through the feveral ftages of command, diftinguifhed by ftrength and hardinefs of body, and the military virtues of courage and obedience. He fought under the emperors Aurelian and Probus on the banks of the Danube, Rhine, Euphrates, and borders of the ocean, acquiring the talents of an experienced foldier, if not of a great general. His manners were not changed in his progrefs, but he remained rude and ferocious, with a propenfity to the groffeft debauchery. In the courfe of his fervice, he contracted an intimacy with his fellow-foldier Dioclefian, who, when elevated to the imperial dignity, remembered the valour, courage, and hardihood of Maximianus, and rewarded his fidelity by making him his colleague in the empire, and by ceding to him the command of the provinces of Italy, Africa, and Spain, and the reft of the weftern territories of Rome. The perfonal fuperiority of Dioclefian was, however, recognized in the affumed epithet of *Jovius*, while Maximian took that of *Herculius*. Maximianus fhewed the juftnefs of the choice of Dioclefian by his victories over the Barbarian tribes with whom he was called to contend. As foon as Dioclefian entered into the twentieth year of his reign, he celebrated, in conjunction with Maximian, that memorable era, as well as his own great fucceffes, by the pomp of a Roman triumph. (See DIOCLESIAN.) This triumph was dignified by feveral circumftances of fuperior celebrity and good fortune. Africa and Britain, the Rhine, the Danube, and the Nile, furnifhed their refpective trophies; but the moft diftinguifhed ornament was of a more fingular nature, a Perfian victory, followed by an important conqueft. The reprefentation of rivers, mountains, and provinces were carried before the Imperial car. The images of captive wives, the fifters and the children of the great king, afforded a new and grateful fpectacle to the vanity of the people. Not long after this, a fevere illnefs infpired Dioclefian with the defign of abdicating his power, which refolution he carried into

into effect in the month of April or May, 305. Maximian was induced by his authority to follow his example, and on the same day divested himself of the purple at Milan, and retired to a delightful villa in Lucania. In the course of a few months, as we have seen in the article MAXENTIUS, he, at the desire of his son, re-assumed the imperial dignity, and was now anxious that this son should yield all authority into his hands. This singular contest for empire between father and son, and its decision, have already been noticed. Maximian retired in confusion into Illyricum, and endeavoured to engage Galerius in his cause. Disappointed in his expectations, he returned to the court of his son-in-law, Constantine, apparently contented with his lot, but in truth watching an opportunity for recovering his power; and while Constantine, in 309, was engaged on the banks of the Rhine in repelling an invasion of the Franks, he spread the report of Maxentius' death, and hastily resumed once more the ensigns of office. The intelligence of this event caused Constantine to return speedily into Gaul, who seized upon Maximian, and confined him to the palace under strict watch; but without intending to inflict a severer punishment. The clemency of Constantine inspired Maximian with the dark design of murdering him; and he had the wickedness and temerity to solicit his daughter Fausta to join him in the conspiracy. She informed her husband of the plot, and through their contrivance, a slave, who was an eunuch, was placed in the emperor's bed, whom Maximian stabbed to the heart, on the supposition that it was his master. Upon this detection he was judged unworthy to live, and being permitted to choose his death, he strangled himself. Such is the generally accredited account; but Gibbon represents the matter differently: he says, that Maximian was delivered into the hands of his son-in-law by the treachery of his army, in consequence of which, a secret and irrevocable sentence of death was pronounced against the usurper, and he obtained the same favour which he granted to Severus, and it was published to the world, that, oppressed by the remorse of his repeated crimes, he strangled himself with his own hands. "After he had lost the assistance, and disdained the moderate counsels of Dioclesian, the second period of his active life was a series of public calamities and personal mortifications, which were terminated in about three years by an ignominious death. He deserved his fate; but we should find more reason to applaud the humanity of Constantine, if he had spared an old man, the benefactor of his father, and the father of his wife. During the whole of this melancholy transaction, it appears that Fausta sacrificed the sentiments of nature to her conjugal duties." Gibbon. Univer. Hist.

MAXIMILLIAN I., emperor of Germany, born in 1459, was son of the emperor Frederic IV. In early life he was so dull and apparently deficient, that he was for several years considered rather in the light of an ideot. About ten years of age he became remarkably addicted to learning, and acquired, with surprising quickness, the Latin, French, and Italian languages. In his twentieth year his father effected a marriage between him and Mary, the heiress of the great house of Burgundy. Lewis XI. of France having seized part of her inheritance in the Low Countries, Maximillian made war against him, defeated his troops, and recovered great part of the usurped territories. He also suppressed the revolts which broke out in various parts of the Low Countries. As he was proceeding in a career of success, he had the misfortune to lose his wife, a circumstance that gave a shock to his authority, and the guardianship of his children was immediately contested by the states. A civil war ensued, which at length was accommodated on the condition that he should continue tutor to his son Philip, under restrictions. In 1486, Maximillian was elected king of the Romans, and crowned at Aix-la-Chapelle: upon his arrival at Bruges to meet the states-general in 1488, the inhabitants ran to arms to secure his person, being suspicious that he was inimical to their rights and liberties; at the same time they imprisoned some of his counsellors, four of whom they beheaded. The people of Ghent followed their example; but, after suffering a kind of imprisonment for ten months, he was liberated. In 1493, he succeeded, by the death of his father, without opposition, to the imperial dignity. He marched at the head of an army against the Turks, who had invaded Croatia, but they retreated before he could reach them. In 1494, he took for his second wife Blanche, the sister of John Galeazzo, duke of Milan, an alliance which engaged him in the affairs of Italy; and when Charles VIII. of France had made himself master of the kingdom of Naples, Maximillian joined in the confederacy of the pope, the king of Spain, and several Italian powers to oppose his arms. He also effected a marriage between his son Philip and the infanta Jane, daughter of Ferdinand and Isabella, by which the Low Countries eventually fell under the dominion of Spain. After the retreat of Charles from Italy, Maximillian, in 1496, engaged in an expedition into that country, and laid siege to Leghorn; but, failing in his attempts, he returned with disgrace. He next attempted to reduce the Swiss; but seven defeats, within six months, made him glad to terminate the war in 1500 by a treaty. After the death of his son Philip, in 1507, he obtained the regency of the Low Countries, of which he constituted his daughter Margaret gouvernante. The famous league of Cambray against the Venetians took place in 1509, to which Maximillian was one of the contracting parties. His troops took possession of Friuli and Istria, and he, at the head of a great army, laid siege to Padua, but was obliged to abandon the enterprize. When pope Julius deserted the league and declared war against the French, Maximillian endeavoured to get him deposed, in order that he himself might succeed to the papacy; but his scheme entirely failed. For a large subsidy he engaged to assist Henry VIII. in his invasion of France; but failing in his engagement, he came in person with a few German troops, and flattered the vanity of the English monarch, as well as gratified his own avarice, by serving under him for the pay of a hundred crowns a day. On the accession of Francis I. he made peace with that monarch, who thereby regained the Milanese. He took little or no part on the subject of the Reformation at its commencement; but at the solicitation of the monks he applied to Leo X. to terminate the religious disputes by his own decision, and he summoned Luther to appear, with the promise of a safe conduct, before the diet of Augsburg. He was particularly anxious to secure the succession to the imperial crown for his grandson Charles; but in the midst of his cares on this subject he died in January, 1519. In his private character he was amiable and respectable; but as a public man he wanted that decision which constitutes true dignity in a prince. He was beneficent and humane, and his memory is still cherished in Germany for abolishing the famous secret tribunal of Westphalia. He was author of some poems, and composed memoirs of his life. Univer. Hist.

MAXIMILLIAN II., emperor of Germany, son of Ferdinand, was born at Vienna in 1527. He was educated in Spain under his uncle, Charles V., whose daughter he married, and he governed that country three years in the name of his father-in-law. After his father had ascended the imperial

imperial throne, he conferred on Maximillian, in 1562, the crowns of Hungary and Bohemia, and caused him to be elected king of the Romans; and upon the death of Ferdinand, in 1564, he succeeded to the empire without any opposition. He was already distinguished for prudence and moderation, and well acquainted with the languages and dispositions of the various people under his sway. The spirit of his administration was pacific, and his reign, for the most part, tranquil. The Protestants of Austria, who had been very useful to the emperor in lending him money to carry on the Turkish war, and afterwards cancelled the debt, requested to be indulged in the free exercise of their religion, which he readily granted. He was not contented to do good himself, but endeavoured, by all the means in his power, and by strong remonstrances to his cousin, Philip king of Spain, to put a stop to the cruelties exercised by Alva in the Low Countries; but that bigot refused to listen to his advice, or to follow his example. Actuated by the same principles, he forbad Charles IX. to make levies in Germany for the purpose of exterminating the French Hugonots, though he could not prevent the Protestant princes of Germany from sending succours to their persecuted brethren in France. Twice he solicited the crown of Poland, with the intention of conveying it to his second son, but want of activity prevented him from attaining his object: he had, however, been successful in securing to his eldest son Rodolph the reversion of the empire, and of the kingdoms of Bohemia and Hungary, and avowed his intention of supporting his claim to the kingdom of Poland by force of arms; but this purpose, if real, was defeated by his death, which happened in 1576. He had, it was said, for some time previously to the event, devoted many of his leisure hours to the contemplation of a future state; and had been accustomed to discourse, in his familiar parties, upon the immortality of the soul, which he looked to not only without terror and dismay, but with hope and Christian confidence. Maximillian II., says the historian, "appears to have been one of the most amiable princes that ever swayed the imperial sceptre. No individual ever complained of having heard a harsh expression from his lips, none ever departed dissatisfied from his audience. So regular were his economical arrangements, that to every act of his life its appropriate hour was allotted; and every day after dinner the meanest of his subjects was at liberty to approach him. A faithful husband, an affectionate parent, and a passionate lover of truth, his example had considerable influence on the manners of his people, and the empire flourished in a peculiar manner under his administration." Univer. Hist.

Maximillian, duke of Bavaria in the 17th century, was called, on account of his courage and success, the Defender of Germany; and, for his singular prudence, he acquired the name of Solomon. He zealously opposed the Protestants, and was considered as one of the principal supporters of the Catholic religion. In 1620, he gained the battle of Prague against Frederic, prince palatine, who had been elected king of Bohemia. For these services Maximillian was named an elector of the empire. He died in 1651, aged 70. Moreri.

MAXIMIN, St., in *Geography*, a town of France, in the department of the Var, and chief place of a canton, in the district of Brignolles; 20 miles N. of Toulon. The place contains 3717, and the canton 9778 inhabitants, on a territory of $412\frac{1}{2}$ kiliometres, in nine communes. N. lat. 43° 28'. E. long. 5° 55'.

MAXIMINUS, Caius Julius Verus, in *Biography*, a Roman emperor, raised to this high rank from almost the lowest class of society, was born in Thrace, A.D. 183. His father was a barbarian of the Gothic nation, his mother an Alan, and he himself was brought up to attend the herds and flocks. In this station he had frequent opportunities of exhibiting his prowess in combating the bands of robbers who overran the country. He is said to have attained to a gigantic stature, and a correspondent strength of body, which produced, in an uncultivated mind, a savage and ferocious character. He was both the pride and the dread of his district, at the time when the emperor Severus, returning from the East, halted in Thrace, to celebrate the birthday of his son Geta. "The country," says Gibbon, "flocked in crowds to behold their sovereign, and a young barbarian of gigantic stature earnestly solicited, in his rude dialect, that he might be allowed to contend for the prize of wrestling. As the pride of discipline would have been disgraced in the overthrow of a Roman soldier by a Thracian peasant, he was matched by the stoutest followers of the camp, sixteen of whom he successively laid on the ground. His victory was rewarded by some trifling gifts, and a permission to enlist in the troops. The next day, the happy barbarian was distinguished above a crowd of recruits, dancing and exulting after the fashion of his country. As soon as he perceived that he attracted the emperor's notice, he instantly ran up to his horse, and followed him on foot, without the least appearance of fatigue, in a long and rapid career. "Thracian," said Severus, with astonishment, "art thou disposed to wrestle after thy race?" Most willingly, sir, replied the unwearied youth; and, almost in a breath, overthrew seven of the strongest soldiers in the army. A gold collar was the prize of his matchless activity, and he was immediately appointed to serve in the horse-guards who always attended on the person of the sovereign." As a soldier he distinguished himself no less by his attention to military discipline than by his valour, and his ferocity bent to the spirit of obedience and subordination. Under Caracalla he rose to the rank of centurion, but he nobly refused to serve under the assassin of that prince, and retiring to his native place he purchased property, and carried on a commerce with the barbarous tribes from which he derived his origin. During the reign of the monster Heliogabalus he kept at a distance from the court, notwithstanding the solicitations of his friends to take a military tribuneship. Alexander Severus knew the worth of Maximinus, and committed to his care a legion of new recruits; the duties of which station he fulfilled with the utmost assiduity, bestowing the minutest attention upon their exercise, arms, health, and apparel. When he was told by a person of considerable rank, that in such a career of promotion he need not trouble himself, he indignantly replied, "I am of a different opinion, the higher I rise the more I shall labour." Though, as an officer, he was a strict disciplinarian, his manners, and the figure of his person, rendered him extremely popular among the soldiery, who gave him the appellations of Ajax and Hercules. His elevation began to inspire him with ambitious views, which effaced the sentiments of affection, gratitude, and duty: he aspired to the throne, and was proclaimed, by the army, emperor, in the year 235. The decree of the soldiery was confirmed by an always complying senate, and one of his first acts was to confer on his son, a youth of fine talents, the title of Cæsar. His heart now became callous to the feelings of honour and humanity; he not only removed from his presence the friends and advisers of the late emperor, but put many of them to death upon the slightest and most frivolous grounds. A conspiracy against his person afforded him a better pretext for the most sanguinary cruelty, and a vast number of persons of rank lost their lives on the occasion, with various circumstances

circumstances of barbarity. He now became the object of universal dread and detestation, and was, in a short time, such is the progress of vice and cruelty, grounded on ambition, ranked among the most bloody tyrants that ever disgraced the Roman purple. He still had the art to retain the attachment of his army, in whom he confided, and crossing the Rhine into Germany with numerous and well disciplined battalions, he laid waste a wide tract of country with fire and sword, and destroyed a great number of natives who opposed him. In these actions he displayed the skill of a general, with the bravery of a private soldier, and made it sufficiently evident that war was the true theatre of his glory. After two campaigns, he passed the winter of the year 236 at Sirmium, occupied in raising money by the severest exactions, which, by means of his officers, were extended to all the provinces of the empire. The procurator of Africa carried his extortions to such an intolerable excess that a conspiracy was formed against him, to which his life fell a sacrifice; and in the year 238, Maximinus and his son were dispatched by an indignant and suffering people, who, fixing their heads upon spears, displayed them as trophies through the army, who received the intelligence with joy, and united in declarations of fidelity to the senate and its decisions. Maximinus has been reckoned, by ecclesiastical writers, among the persecutors of the Christians, but the candid historian does not readily admit the title of "the sixth persecution" to be justly applied to the reign of this emperor. He is described, by Gibbon, as a brutal savage, destitute of every sentiment that distinguishes a civilized, or even a human being. "The body," says he, "was suited to the soul." The stature of Maximinus exceeded the measure of eight feet, and circumstances almost incredible are related of his matchless strength and appetite. Had he lived in a less enlightened age, tradition and poetry might well have described him as one of those monstrous giants, whose supernatural power was constantly exerted for the destruction of mankind. Gibbon. Univer. Hist.

Maximinus, C. Galerius Valerius, a Roman emperor, son of the sister of the emperor Galerius, was in the year 305, upon the abdication of Dioclesian and Maximinian, raised, by the influence of his uncle, to the rank of Cæsar, and, in the division of the empire, the provinces of Egypt and Syria were placed under his government. When Licinius, in 307, was raised by Galerius to the rank of Augustus, Maximinus, disdaining an inferior title, insisted on the same elevation, and upon some reluctance on the part of Galerius to grant it, he caused himself to be nominated to that dignity by his assembled troops: thus at one and the same time, the Roman world, in the year 308, witnessed six Augusti or emperors. On the death of Galerius, in 311, Maximinus shared his dominions with Licinius, and added Asiatic provinces to his former possessions. In the contest between Maxentius and Constantine, Maximinus secretly allied himself with the former, though he took no open part in the war. When Galerius issued his edict in favour of the Christians, Maximinus, though an enemy to them, thought proper to concur. Still he had a great desire to re-establish the Pagan worship, with all its impostures of magic and divination. He was preparing to renew the persecution, and, in the mean time, he not only gave to the ancient religion a system of church government copied from the Christians, and threw about it all the lustre of the state, but employed every art to discourage and vilify Christianity. He is also charged with having published and carefully disseminated a false narrative of the death of Jesus Christ, filled with the most injurious representations. The principal cities of his dominions, as Nicomedia, Antioch, and Tyre, were instigated to send addresses to him, expressing their abhorrence of the Christians, and imploring that they might be expelled. These, however obtained, led to the infliction of cruel and ignominious punishments and to the destruction of some lives. The dangers that menaced Christianity in Asia were averted by the war, which, in 313, took place between Maximinus and Licinius. The latter had made an alliance with Constantine, and the apprehension of its consequences seems to have been the chief motive of Maximinus, who begun the attack. He was entirely defeated, and was obliged to seek his safety in a rapid flight; and it is said he reached Nicomedia, a distance of 160 miles, in the space of twenty-four hours from the conclusion of the battle. He retreated to Tarsus, where, in a few months, death put an end to his disgrace. His whole family was sacrificed to the vindictive rage of the conqueror. Gibbon. Univer. Hist.

MAXIMUS, M. Claudius Pupienus, a Roman emperor, was the son of a mechanic, but having a desire to enrol himself in the army, he enlisted at an early age, and became distinguished first as a soldier, and afterwards in some of the public offices of state. In 227 he obtained the consulate, and was afterwards proconsul of Bithynia, Greece, and Narbonnensian Gaul, and was appointed to military commands in various parts of the Roman empire. As prefect of Rome, he displayed intelligence, firmness, and severity, so that he acquired a general respect, accompanied with an awe, approaching almost to terror. In 237, when the murder of the Gordians deprived Rome of the emperors it had chosen in the place of the tyrant Maximinus, the merit of Maximus caused him to be invested with the purple together with Balbinus. Some opposition was first made to his accession, and it was resolved to add the younger Gordian, then a child, to the emperors already chosen. At length Maximus was received with joyful acclamations as the deliverer of his country, and the conduct of the three emperors seemed to promise the restoration of an equitable and wise government to the Roman world. The various nature of their talents seemed to appropriate to each his peculiar department of peace and war, without leaving room for a jealous emulation. Justice was regularly administered, wholesome laws were enacted, and oppressive taxes were repealed or moderated. Discipline was revived, and with the advice of the senate many excellent regulations were introduced into the several departments of government. The pretorian bands, accustomed to depose and to make emperors at their pleasure, soon shewed symptoms of discontent under a sovereignty which they had not established, and apprehended that the reign of law and order would be destructive of their power. They accordingly seized upon the opportunity when the citizens were occupied in the Capitoline games, rose in mutiny, and marched towards the palace: laid hold of the two emperors, treated them with every mark of insult, and, to prevent the possibility of a rescue, took away their lives, leaving their bodies, mangled with a thousand wounds, exposed to the insults or the pity of the populace. Gibbon. Univer. Hist.

Maximus, Petronius, an emperor of the West in the fifth century, was a Roman of noble birth. Possessed of an ample patrimony, and adorned with liberal arts and elegant manners, he obtained the favour of the prince and the senate, and of course rose to high and important offices in the state. In March 455, Maximus was elected emperor, in the room of Valentinian, who had, on account of his vices and tyranny, been assassinated. In a few hours he was convinced that happiness and sovereignty were generally at variance, and he was heard to exclaim, "Happy Damocles, whose reign began and ended with a dinner!" His own power was very short-lived; when attacked by Genseric, king of the Vandals, in Africa, he was deprived of all courage and presence of mind, and thought of nothing but how to make his escape. Cowardice in a prince is always hateful and contemptible, and as soon as his intentions were known, the people, who would probably have rallied round him, had he been inclined to defend his country, rose upon him, and a soldier gave him a fatal blow. His body was ignominiously dragged through the streets and thrown into the Tiber. Such was his end, after a reign of less than three months. Gibbon. Univer. Hist.

Maximus Magnus, an imperial usurper of the fourth century, a native of Spain, and probably of low origin, served in Britain with Theodosius, afterwards emperor, and established a character for valour and abilities, though it does not appear that he rose to any important rank, either civil or military. He was invested with the imperial purple in the year 383, by the army among whom he had excited discontent and disaffection against Gratian, emperor of the West. This took place while he was in Britain, but he determined to carry his arms to the continent, and contend with the lawful emperor upon his own ground. He transported into Gaul so great a number of Britons, that the emigration at that period weakened the population of the island, and they afterwards settled in Bretagne. As he advanced he was joined by the Gallic armies, and even the houshold troops deserted Gratian, then resident at Paris. He fled before the usurper, and was put to death at Lyons. Maximus was now acknowledged as emperor by all the provinces of the West, and he declared his infant son Victor his colleague, and proposed an alliance to Theodosius, emperor of the East, which was accepted, on condition that he should not pass the Alps, beyond which Valentinian, the brother of Gratian, reigned over Italy, Illyrium, and Africa. The ambition of Maximus, however, would not permit him to rest; in 387 he invaded Italy, and took possession of Milan, without opposition. Valentinian fled to implore the assistance of Theodosius, who, while the usurper was employed in reducing the towns of Italy, levied an army to oppose him. A battle decided the fate of Maximus; as soon as he was defeated, his own soldiers rose upon him, dragged him away and struck off his head. His son Victor met with a similar fate in Gaul. These events took place in the year 388. Maximus is stigmatized as the first Christian prince who shed the blood of his Christian subjects, on account of their religious opinions. Gibbon. Univer. Hist.

Maximus Tyrius, a celebrated philosopher, and elegant writer in the second century, was a native of Tyre in Phœnicia, whence he derived his name. He probably came to Rome in the year 146, where he received from the emperor Marcus Aurelius many tokens of esteem and regard. This emperor is said to have placed himself under the instructions of the philosopher, though some writers imagine that this high honour belonged to another Maximus of the Stoical sect. Maximus adopted the principles of Plato, but with an evident leaning to scepticism. There are forty-one of his "Dissertations," on philosophical topics, still extant, which display much sound argument, and real eloquence. These have been very frequently printed. The first Latin version was published at Basil in 1519, and the original Greek was printed for the first time by Henry Stevens, in 1557. In 1607, Daniel Heinsius published an edition of them at Leyden, in Greek and Latin, illustrated with notes. A new impression of this edition was printed at Cambridge in 1703, with corrections, additional notes and indexes, by Dr. John Davies. Enfield. Hist. Phil. Harwood.

Maximus, named "The Cynic," a native of Ephesus, who studied under Œdesius of Cappadocia, a philosopher of the Eclectic school, and immediate successor of Jamblichus. He was probably appointed by the emperor Constantius preceptor to Julian, surnamed afterwards "The Apostate." Some writers, however, maintain that he introduced himself to that emperor at Nicomedia, either while he was pursuing his studies, or during his expedition into the East. Whichever account be true, it is certain he was a great favourite with Julian, and had such an influence over his mind, as to excite in him the most determined hatred to Christianity, while he inspired him with an ardent attachment and enthusiasm in favour of Heathen superstitions, and the practice of pretended magical arts. Such, at length, was the folly of the deluded emperor, that he seemed to place an entire confidence in the predictions of Maximus. When the emperor intended to make war against Persia, he had recourse to his divinations, which flattered him with the idea, that he was born to rival Alexander in the glory of conquest. The event shewed the vanity of the prophet, and the emperor fell a sacrifice to his credulity. During the reign of Jovian, Maximus was treated with respect; but under the government of Valentinian and Valens he was seized and prosecuted for the crime of magic, of which he was convicted and sentenced to a long imprisonment. In 373, he was put to death by the proconsul Festus, the distinguished minister of the emperor Valens' cruelties. Enfield. Hist. Phil.

MAXINO, in *Geography*, a town of Sweden, in the government of Wasa; 12 miles N.N.E. of Wasa.

MAXULA, Mo-raisah, in *Ancient Geography*, an ancient town of Africa, situated on the sea-coast, S.E. of Carthage. It is mentioned by Ptolemy, Pliny, and Antonine in his Itinerary.

MAXY, in *Mineralogy*, a name given by some to mundic, a sulphureous mineral, common in the tin-mines of Cornwall, and elsewhere.

MAXYES, in *Ancient Geography*, a people of Africa, in Libya, W. of the river Triton. According to Herodotus, they permitted their hair to grow on the right side of the head, shaved the left side, and painted their bodies with vermilion. They are said to have been descended from the Trojans, and to have inhabited a very mountainous country, covered with wood and full of wild beasts.

MAY, Maius, the fifth month in the year, reckoning from our first, or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called *Maius* by Romulus, in respect to the senators and nobles of his city, who were named *majores*, as the following month was called *Junius*, in honour of the youth of Rome, *in honorem juniorum*, who served him in the war; though some will have it to have been thus called from *Maia*, the mother of Mercury, to whom they offered sacrifice on the first day of it; and Papias derives it from *Madius*, *eo quod tunc terra madeat*.

In this month the sun enters Gemini, and the plants o the earth in general begin to flower.

The month of May was under the protection of Apollo; and in it also they kept the festival of Bona Dea, that of the goblins, called *lemuria*; and the ceremony of *regifugium*, or the expulsion of the kings.

The vulgar have a great opinion of the virtues of May-dew, and May-butter.

The month of May has ever been esteemed favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reason may perhaps be referred to the feast of the Lemures,

mures, which was held in it. Ovid alludes to this in the fifth of his Fasti, when he says,

"Nec viduæ tædis eadem, nec virginis apta
Tempora; quæ nupsit, non diuturna fuit:
Hac quoque de causa, si te proverbia tangunt,
Mense malum Maio nubere vulgus ait."

MAY-*apple*, in *Botany*. See PODOPHYLLUM.

MAY-*bush*. See CRATÆGUS.

MAY-*dew*. See DEW.

MAY-*duke*, a species of cherry.

MAY-*lily*. See CONVALLARIA.

MAY-*weed*. See ANTHEMIS and MATRICARIA.

MAY-*weed*, in *Agriculture*, the common name of a troublesome kind of field weed, which resembles wild chamomile, and is a trailing perennial plant, which puts out roots from its branches as they lie on the ground. By these means, and by scattering its seeds long before the corn is ripe, it spreads and multiplies greatly. It flowers in May, whence its name . With regard to the best means of extirpating it, they are those of summer fallowing, repeated good harrowing, and burning the collected roots. What escapes these clearings should be very carefully pulled up by hand; for the common weeding-hook will not go deep enough to take out the whole of the long slender tap root of this plant, of which every remaining bit that has a knot in it will produce new shoots. The farmer should not regret this small additional expence, to get rid of one of the most fatal enemies his corn can have. Mr. Lisle observes, that a "good crop of wheat in the winter time, was so destroyed by the coming up of May-weed and poppies in the spring and summer, that it did not at last yield so much as the seed." Where proper tillage is practised, this can never be the case.

MAY-*wort*, in *Botany*. See ARTEMISIA.

MAY, THOMAS, in *Biography*, eldest son of sir Thomas May, knight, of Mayfield in Sussex, was born in 1595. He pursued his studies in Sidney college, Cambridge, where he took his degree of B.A.; after which he entered himself a member of Gray's Inn, with the view of studying the law, though he probably never pursued it as a profession. He was much attached to literature, and became acquainted with the poets and men of wit who flourished in that period. Owing to the extravagance of his father, he had only a small annuity to depend upon. Some of his first compositions were of the dramatic class, and three tragedies and two comedies are extant in his name. He translated "Virgil's Georgics," "Selected Epigrams of Martial," and "Lucan's Pharsalia," with a continuation of the poem to the death of Julius Cæsar, in seven books, of his own composition; which have been so much admired, as to be given with several of the best editions of Lucan. This has rendered his name famous among classical scholars. He was author of many original poems, such as "The Reign of Henry II.," "The victorious Reign of Edward III.," "The Description of Henry II. with a short Survey of the Changes of his Reign," and "The single and comparative Character of Henry and Richard his Sons." He was in high estimation with king Charles I., who designated him as his poet; but the monarch was not sufficiently liberal to secure the poet's attachment. He even quitted the royal party, upon the breaking out of the civil wars, and entered into the service of the parliament. He was appointed secretary to the parliament, and wrote a history of its transactions; which work became famous, and was extremely obnoxious to the royal party. Clarendon speaks with great contempt of his performance, but Granger affirms that it is a very respectable work. It was his last literary labour. He died in November 1650. His consideration with his party was shewn by a splendid public funeral in Westminster Abbey, with a marble monument and a laudatory epitaph. After the restoration, the royalists took their revenge, dug up his body, which they treated with ignominy, and tore down the monument intended to perpetuate his fame. Biog. Brit.

MAY, in *Geography*, a river of America, in South Carolina, which runs into the Atlantic, N. lat. 32° 15′. W. long. 80° 55′.—Also, a river of Chiampa, which runs into the Chinese sea, N. lat. 10° 42′. E. long. 107° 14′.—Also, a town of Persia, in the province of Farsistan; 120 miles S. of Schiras.—Also, a small island of Scotland, at the entrance of the Frith of Forth, formerly dedicated to St. Adrian, who was murdered by the Danes. On it is a lighthouse; five miles S. of Fifeness. N. lat. 56° 10′. W. long. 2° 38′.

MAY. See MAYO.

MAY, *Cape*, the most southerly point of land of New Jersey, and the N. point of the entrance into Delaware bay and river in N. lat. 39°. W. long. 74° 51′.

MAY, *Cape*, *County*, extends northward round the forementioned cape, and is a healthy, sandy tract of country, 34 miles long, and 19 broad. This county is divided into Upper, Middle, and Lower precincts. The number of inhabitants is 3066, of whom 98 are slaves.

MAY *Point*, a point of the peninsula, between Fortune and Placentia bays, on the S. side of Newfoundland island.

MAYA, a town of Spain, in Navarre; 21 miles N. of Pamplona.

MAYA, in *Metaphysics*, is a term of vague import among the Brahmans and other Hindoo philosophers. It means *illusion* or *deception*, and is variously applied in cases beyond the reach of demonstration or comprehension. For instance, although their most sacred books give the title of god to the sun, and they confess generally that the sun is an emblem or image of their three great deities, jointly and individually, that is of Brahm, or the Supreme Being, who alone exists really and absolutely, yet the *three forms*, or *trimurti*, are considered as maya, or delusion, as well as the body of the sun; but since the latter is the most glorious and active emblem of God, that luminary is respected as an object of high veneration. This is sufficiently mysterious; but it flows from the principal tenet of the Vedanti school (see VEDANTA): "That the only being which has absolute and real existence is the Divine Spirit, infinitely wise, infinitely benign, and infinitely powerful, expanded through the universe; not merely as the *soul of the world*, but as the ruler of it, sending forth rays or emanations from his own essence, which are the pure vital souls of all animated creatures, whether *moveable* or *immoveable*; or, as we should express it, both *animals* and *vegetables*, and which he calls back to himself, according to certain laws established by his unlimited wisdom." Brahm, as the Most High One, is neuter; in the character of Supreme Ruler he is named Parameswara; but, through the infinite veneration to which he is entitled, the Hindoos meditate on him with silent adoration, and offer prayers and sacrifices only to the higher emanations from him. This silent adoration is by some called Jap, (see that article,) in which description of worship the holy gayatri and the sacred monosyllable O'M is mentally recited. (See O'M.) In a mode, incomprehensible to inferior creatures, they are involved at first in the gloom of maya, and subject to various taints from attachment to worldly affections; but they can never be reunited to their source, until they dispel the illusion by self-denial, renunciation of the world, and intellectual abstraction, and have removed the impurities of their nature

by

by repentance, mortification, and successive transmigratory passages through the forms of animals or vegetables, according to their demerits. In such a reünion consists their final beatitude; and to effect it by the best possible means is the object of their supreme ruler, who, in order to reclaim the vicious, to punish the incorrigible, to protect the oppressed, to destroy the oppressor, to encourage and reward the good, and to shew all spirits the path to their ultimate happiness, has been pleased (say the Brahmans) to manifest himself in a variety of ways, from age to age, in all parts of the habitable world. When he acts immediately without assuming a shape, or sending forth a new emanation; or when a divine sound is heard from the sky, that manifestation of himself is called *Akasavani*, or an ethereal voice: when the sound proceeds from a meteor, or a flame, it is said to be *Agnipuri*, or formed of fire: a descent of the deity in the shape of a mortal, is an avatara. Of this last description there have been many; but the chief of them as detailed in the Puranas, and to which the word is generally applied, are the ten, or *dasavatara*, of Vishnu; as enumerated under the article VISHNU, and described briefly under the references therefrom. A similar incarnation of an inferior kind, intended to answer some purpose of less moment, is called *Avantara*. Of this description is that noticed under KANDEH RAO; though in common language called also *avatara*. The supreme being, and the celestial emanations from him, are *nirakara*, or bodiless, in which state they must be invisible to mortals; but when they are *pratyaksha*, or visible, they become *sakara*, or embodied, and expressive of the divine attributes; thus Krishna revealed himself to Arjun, as described in an extract from the Gita under the article KRISHNA, or in a human form, which Krishna usually bore. And in that mode of appearing, the deities are generally supposed to be born of a woman, but without any carnal intercourse. The excessive libertinism of Krishna, his sectaries declare to be apparent only; he was chaste and pure in reality; such appearances were maya, or delusion.

These doctrines, however, are by no means received by all Hindoos, though they be very popular with certain sects. A reformation of the above, called Purva mimansa, was introduced by Jaimini, who denies the incarnations of deities. See JAIMINI.

Although not particularly in its place, we will here insert four verses translated by sir William Jones from the Bhagavat, one of the Hindoo Puranas, as connecting some of their philosophical tenets. The translation we are assured is "most scrupulously literal."

"Even I was at first, not any other thing; that which exists unperceived, supreme; afterwards *I am that which is*; and he who must remain, am I.

"Except the *First Cause*, whatever may appear, and may not appear, in the mind, know that to be the mind's *maya*, or delusion, as light, as darkness.

"As the great elements are in various beings, entering, yet not entering, (that is, pervading, not destroying,) thus am I in them, yet not in them.

"Even thus far may enquiry be made by him who seeks to know the principle of mind, in union and separation, which must be *every where always*." Asiatic Ref. vol. i.

The above verses are stated to have been spoken by the supreme being to Brahma, and wild and obscure as they are, the learned translator doubts if the poetry or mythology of Greece and Italy afford conceptions more awfully magnificent; the brevity and simplicity of the Mosaic diction is, however, unrivalled.

The first of the four verses above quoted will strongly remind the reader of the inscription in a temple at Sais in Lower Egypt; see the article EGYPT; where farther traces of resemblance will be found between the theogony and philosophy of that country and of India, as exhibited in this, and the other articles connected with Hindoo mythology.

"As the soul of the world, or the pervading mind, so finely described by Virgil, we see Jove represented by several Roman poets; and with great sublimity by Lucan, in the speech of Cato concerning the Ammonian oracle: "Jupiter is wherever we look, wherever we move." This is precisely the Indian idea of Vishnu, according to the four verses above exhibited—not that the Brahmans imagine their male divinity to be the *divine essence* of the Great One, which they declare to be wholly incomprehensible; but, since the power of *pervading* created things, by a superintending providence, belongs eminently to the Godhead, they hold that power to exist transcendently in the preserving member of the Triad, whom they suppose to be *every where always*, not in substance, but in spirit and energy. Here, however I speak of the Vaishnavas, for the Saivas ascribe a sort, of pre-eminence to Siva." Jones, ib. See VAISHNAVA and SAIVA.

The accomplished writer above quoted addressed a spirited hymn to Narayana, and in the argument prefixed says, "that a complete introduction to it would be no less than a full comment on the Vedas and Puranas of the Hindoos, the remains of Egyptian and Persian theology, and the tenets of the Ionic and Italic schools: but this is not the place for so vast a disquisition. It will be sufficient here to notice, that the inextricable difficulties attending the *vulgar notion of material substances*, concerning which 'we know this only, that we nothing know,' induced many of the wisest among the ancients, and some of the most intelligent among the moderns, to believe that the whole creation was rather an *energy* than a *work*, by which the infinite Being, who is present at all times in all places, exhibits to the minds of his creatures a set of perceptions like a wonderful picture, or piece of music, always varied, yet always uniform; so that all bodies and their qualities exist, indeed, to every wise and useful purpose, but exist only as they are *perceived*: a theory no less pious than sublime, and as different from any principle of atheism as the brightest sunshine differs from the blackest night. This *illusive operation* of the Deity the Hindoo phisophers call *maya*, or *deception*." The Berkelyan theory of immaterialism seems to coincide with these doctrines. See BERKELEY.

Maya, in a more mythological view, is described as the mother of Kama, the god of love. Under this personification she represents the general *attracting* power; and some Hindoo scholars explain the word to mean the 'first inclination of the Godhead to diversify himself,' such is their phrase, 'by creating worlds.' She is thus feigned to be the mother of universal nature and of all the inferior gods. Lakshmi, the bounteous giver of all good, is also represented to be the mother of Kama, and one of her appellations is Maya, or Ada-maya, as noticed under LAKSHMI.

MAYA, in *Ornithology*, a name given by the people of the Philippine islands to a small species of sparrow, much less than our's, and very common among them. It feeds on rice, and is very destructive of it.

MAYACA, in *Botany*, a name of which no explanation is given. Aubl. Guian. 42. t. 15. Juss. 45. Lamarck Illustr. t. 36. Michaux Boreal-Amer. v. 1. 26. See SYENA; Schreb. 36. Willd. Sp. Pl. v. 1. 254.

MAYACARI, in *Geography*, a river of Guiana, which runs into the Atlantic, N. lat. 2° 11′. W. long. 51° 46′.

MAYAGUANA, one of the Bahama islands; 24 miles in length. N. lat. 22° 32′ to 22° 44′. W. long. 72° 15′ to 72° 30′.

MAYAHOUN, a town of the Birman empire, on the Irawaddy, which formerly belonged to Pegu, and was called "Loonzey" or "Lundsey." It is large, and contains many temples and convents, besides granaries filled with rice, produced in the environs, and belonging to the king; 120 miles N.N.W. of Rangoon.

MAYALS, a town of Spain, in Catalonia; 16 miles S. of Lerida.

MAYAMBA, a town of Africa, and capital of a province of the same name, in the kingdom of Loango, near the Atlantic ocean. Within its territory, which extends far eastward, is a salt lake, above 15 miles in compass, which empties itself by some rivulets into the sea, about half a league N. of cape Negro. The town stretches along the coast, but lies so low that the inhabitants are frequently under a necessity of removing at high water to some of the neighbouring high lands. The river Banna, which runs near the town, is saltish, and has at its mouth a good fishery for oysters. By means of this river, logwood is brought to the port in canoes from the province of Sette, where it abounds; the river extends 150 miles within land. The soil of Mayamba is dry and sandy, and produces little or no grain, but furnishes plenty of bananas and palm-trees, and of the latter a wine is made, and also roots of maxondo, which they use instead of bread. The lakes and rivers supply abundance of fish, on which the inhabitants chiefly subsist. The oysters are opened and smoked, and are thus preserved in an eatable state for several months. The country abounds with game, which is caught by dogs, with wooden clappers to their necks, by the noise of which they follow them, as they are not able to bark. The government of this province is commonly conferred on a counsellor of state, who is also prince of Loangiri, and gives no account to the king of Loango of any commodities, except of the logwood, which pays a duty of 10 *per cent.* The people are rude and savage, and their governor is an absolute tyrant. The commerce of elephants was formerly considerable and lucrative, but has lately been almost annihilated. S. lat. 3° 20′. E. long. 13° 4′.

MAYAPARA, the proper name of Point Palmiras; which see.

MAYAPIL, a town of Mexico, in New Biscay; 75 miles S.S.E. of Parral.

MAYAPOUR, a town of Bengal; eight miles S.W. of Palamow.—Also, a town of Bengal; 12 miles S.W. of Calcutta.

MAYAR, a town of Persia, in the province of Irak, containing about 300 houses, and a caravansera; 24 miles S. of Ispahan.

MAYASQUER, a town of South America, in the audience of Quito; 70 miles N. of Quito.

MAYBACA, a river of Guiana, which runs into the Atlantic, N. lat. 6° 40′. W. long. 58° 26′.

MAYBOLE, or MINNEBOIL, a town of Scotland, in the county of Ayr, which has manufactures of woollen and cotton. The population returned to parliament in 1791 was 3162, of whom 1626 were employed in manufactures, chiefly of blankets. At this time here were ten persons, whose ages amounted together to upwards of 900 years; 18 miles S. of Ayr.

MAYCAWINI, a river of Guiana, which runs into the Atlantic, N. lat. 6° 35′. W. long. 58° 26′.

MAYCOCK BAY, a bay on the W. coast of Barbadoes; three miles N. of Speight's town.

MAYDOOH, a town of the Birman empire; 42 miles S.W. of Monchaboo.

MAYEM, a town of Hindoostan, in Baglana; 20 miles N. of Basseen.

MAYEN, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Coblentz; 15 miles W. of Coblentz. The place contains 2200, and the canton 5358 inhabitants, in 15 communes. N. lat. 50° 26′. E. long. 7° 8′.

MAYEN'S *Island*, an island lying S.W. of Spitzbergen; formerly resorted to for the whales which frequented its coast, but now forsaken, as these fishes have removed farther north. A very high mountain, called Beerenbergen, or Bear mountain, extends quite across the island, which may be seen from the sea, at the distance of 30 miles. This island has many good bays, and the land abounding with deer, and the coast with fish, render it habitable; but the floats of ice, towards the E. especially, make it inaccessible in spring. N. lat. 71° 13′.

MAYENCE. See MENTZ.

MAYENNE, CHARLES *of Lorraine, Duke of*, in *Biography*, second son of Francis of Lorraine, duke of Guise, was born in 1554. He displayed great courage at the sieges of Poictiers and Rochelle, and at the battle of Montcontour. He also defeated the Protestants in Guienne, Dauphiny, and Saintonge. When his brothers were killed at the meeting of the states at Blois, he declared himself head of the league, and assumed the title of lieutenant-general of France. He proclaimed the cardinal of Bourbon king, by the name of Charles X.; but was defeated by Henry IV. at the battle of Arques, and again at Ivry. In 1599 he was reconciled to the king, who made him governor of the Isle of France. He died in 1611. Moreri.

MAYENNE, in *Geography*, a town of France, and capital of a department of the same name, and principal place of a district, near the river Mayenne, defended by a castle on a rock: the river rises near Linieres in the department of the Charente, and passing by Ambrieres, Mayenne, Laval, &c. joins the Sarthe, about three miles N. from Angers, and forms the Mayne, which joins the Loire, about four miles below. The town contains 7575 inhabitants; one of its cantons contains 14,834, on a territory of 162½ kiliometres, in eight communes, and the other contains 14,946 inhabitants, on a territory of 200 kiliometres, in twelve communes.

MAYENNE, one of the nine departments of the N.W. region of France, formerly Lower Maine, lies in N. lat. 48° 15′, and is bounded on the N. by the departments of the Channel and the Orne, on the E. by the department of the Sarthe, on the S. by the Mayne and Loire, and on the W. by that of the Ille and Vilaine. Its length is about 22 French leagues, and breadth 16; its extent is 5452½ kiliometres, or about 266 square leagues, and the number of its inhabitants is computed at 328,397. It is divided into three circles, 27 cantons, and 288 communes. Its circles are Mayenne, including 157,256 inhabitants in 116 communes; Laval, containing 106,141 inhabitants in 93 communes; and Chateau-Gontheir, having 65,000 inhabitants in 79 communes. According to M. Hassenfratz, this department comprehends seven circles, 68 cantons, and 323,607 inhabitants. Its contributions in the 11th year of the French era amounted to 3,111,618 fr., and its expences for administration, justice, and public instruction, were 234,804 fr. Its capital is Laval. A great proportion of this department is hilly and covered with forests; it has many sandy tracts, and few cultivated plains. The borders of the rivers Sarthe and Mayenne yield some grain, fruits, and pastures in abundance.

Here

Here are mines of iron, quarries of marble and ſtone, mineral ſprings, &c.

MAYENNE, or MAYNE, *and Loire*, ſo called from the union of two rivers, formerly Anjou, is one of the nine departments of the weſtern region of France, lying in N. lat. 47° 20′, and bounded on the N. by the departments of the Mayenne and Sarthe; on the E. by the department of the Indre and Loire; on the S. by the departments of the Vendée, the Two Sevres, and the Vienne; and on the W. by the department of the Lower Loire. Its length is 26 French leagues, and breadth 21 leagues; and its territorial extent is 7637½ kiliometres, or about 370 ſquare leagues; and its number of inhabitants is 376,033. It is divided into five circles or diſtricts, 34 cantons, and 385 communes. The circles are Segré, comprehending 58,176 inhabitants in 77 communes; Baugé, including 60,669 in 61 communes; Saumur, having 90,104 in 115 communes; Beaupreau, with 74,650 in 73 communes; and Angers, having 92,434 in 59 communes. According to M. Haſſenfratz, the circles are eight, the cantons 99, and the number of inhabitants 445,500. Its contributions in the 11th year of the French era amounted to 4,182,024 fr. and its expences for adminiſtration, juſtice, and public inſtruction, were 348,331 fr. 99 cents. Its capital is Angers. This department, diverſified with hills and plains, yields grain, flax, hemp, fruits, abundant paſtures, conſiderable foreſts, mines of coal, &c. and quarries of marble, ſtone, and ſlate.

MAYEPEA, in *Botany*. See CERANTHUS, and CHIONANTHUS *Incraſſata*. Notwithſtanding the doubts of our learned predeceſſor in the place laſt cited, we are convinced that this genus of Aublet and Schreber is rightly referred by Swartz and Vahl to *Chionanthus*, and that Juſſieu was widely miſtaken in ranking it among his *Rhamni*.

MAYER, JOHN FREDERIC, in *Biography*, a learned German divine in the ſeventeenth century, was born at Leipſic in 1650; he acquired a profound knowledge of the ancient languages, and became profeſſor at ſeveral of the univerſities of his country. He died in 1712 with a high character for learning. He was author of "Bibliotheca Biblica," which treats of the moſt celebrated commentators of the ſcriptures; a treatiſe "On the beſt Method of ſtudying the Sacred Scriptures;" "The Hiſtory of Martin Luther's German Verſion of the Bible, with a ſhort Account of the Tranſlations of the Sacred Books before his Time;" and other pieces. Moreri.

MAYER, TOBIAS, a German aſtronomer and mechanician, was born at Marpach, in Wirtemburg, in the year 1723. At the very early age of four years he ſhewed a ſtrong attachment to the mechanical arts, and actually began to deſign and conſtruct little machines with dexterity and accuracy. His father was a civil engineer, and encouraged him in his purſuits; but upon his death the ſon was left almoſt deſtitute, and was obliged to depend on his own energies for future ſupport. By theſe he made himſelf acquainted with mathematical learning, and qualified himſelf in a ſhort period to be an able inſtructor of others. He acquired, at the ſame time, a conſiderable ſhare of claſſical knowledge, ſo as to be able to write the Latin tongue with elegance. At the age of twenty-eight, he was nominated mathematical profeſſor at the univerſity of Gottingen, and ſoon after was admitted a member of the Royal Society in that town. From this time every year of his life was diſtinguiſhed by diſcoveries in geometry or aſtronomy. He invented many uſeful inſtruments for the meaſurement of angles: he applied himſelf to ſtudy the theory of the moon: he extended his obſervations to the planet Mars, and the fixed ſtars, determining the places of the latter, and aſcertaining that they poſſeſs a certain degree of motion relative to their reſpective ſyſtems. Towards the cloſe of his ſhort life the magnetic needle engaged his attention, to which he aſſigned more certain laws than thoſe before received. To all his purſuits he applied with ſuch indefatigable aſſiduity, that he died literally worn out with labour in 1762, at the age of thirty-nine. The principal works which he gave to the public were, "A New and General Method of reſolving all geometrical Problems, by means of geometrical Lines;" "A mathematical Atlas, in which all the mathematical Sciences are compriſed in ſixty Tables;" "A Deſcription of a Lunar Globe, conſtructed by the Coſmographical Society of Nuremberg, from New Obſervations;" "Maps;" and ſeveral valuable papers in the Memoirs of the Royal Society of Gottingen. His table of refractions, deduced from aſtronomical obſervations, agrees with that of Dr. Bradley; and his theory of the moon, and aſtronomical tables and precepts, were ſo well received, that they were rewarded by the Engliſh Board of Longitude with the premium of three thouſand pounds, which ſum was paid to his widow after his deceaſe. Theſe tables and precepts were publiſhed in 1770.

MAYERGA, in *Geography*, a town of Spain, in the province of Leon; 23 miles S S.E. of Leon.

MAYERNE, *Sir* THEODORE TURQUET DE, BARON D'AUBONNE, in *Biography*, an eminent phyſician, was born at Geneva in the year 1573. His father, Lewis de Mayerne, author of "A General Hiſtory of Spain," and of "The Monarchie ariſto-democratique," and a Calviniſt, had removed thither the preceding year, on account of religious perſecution, from Lyons. After being inſtructed in the rudiments of literature in his native city, Theodore was ſent to the univerſity of Heidelberg, where he remained ſome years; after which, as he had made choice of the profeſſion of medicine, he removed to Montpellier, where he received the degree of doctor in 1597. He then went to Paris, where he became acquainted with Riverius, firſt phyſician to king Henry IV., through whoſe influence he was, in the year 1600, appointed to attend the duke de Rohan, as phyſician, in his embaſſy to the diet at Spire; and alſo nominated one of the phyſicians in ordinary to the king. On his return, he availed himſelf of the privilege which the latter office afforded him, and practiſed in the metropolis, where he alſo gave public lectures in anatomy and in pharmacy to the young ſurgeons and apothecaries. The latter of theſe ſubjects led him to treat of chemiſtry, to the practice of which he had paid peculiar attention; and his recommendation of chemical remedies drew upon him a conſiderable degree of enmity from the faculty of Paris, who manifeſted their attachment to Galen, by an indiſcriminate abuſe of all who ventured to employ any mode of treatment not mentioned in his works. Quercetanus was joined with Mayerne in this attack; and one of the faculty, in 1603, publiſhed a book againſt theſe heterodox brethren, entitled "Apologia pro Hippocratis et Galeni Medicina, contra Mayernium et Quercetanum." To this Mayerne replied immediately in another "Apologia, in qua videre eſt, inviolatis Hippocratis et Galeni legibus, Remedia chemicè præparata tutò uſurpari poſſe," in which he made ſome ſevere ſtrictures on the Pariſian phyſicians. The Galeniſts, however, not only replied, but proceeded to iſſue a decree of the faculty againſt conſulting with him, conceived in very bitter and abuſive terms. But the eſteem of Henry IV., which he had fully obtained, ſo far ſupported him, that he continued to practiſe in Paris, and would have been appointed firſt phyſician to the king, provided he would have embraced the Catholic religion. Even in ſpite of his unyielding adherence to Proteſtantiſm, the king would have given him that appointment, had not the Jeſuits influenced queen Mary de Medicis to interpoſe and prevent it. In 1607, an Engliſhman of rank, who had been his patient, carried him over to England, and introduced him to the royal family. He returned to Paris, and remained there till after the aſſaſſination of Henry IV., which took place in May, 1610. In the following year, he received an expreſs invitation from king James I. to come and take the office of his firſt phyſician, which he accepted, and paſſed the reſt of his life in England, where he appears to have been conſidered as the firſt perſon in the profeſſion. He was admitted to the degree of doctor in both univerſities, and into the College of Phyſicians, and treated with the greateſt reſpect by theſe learned bodies. He incurred ſome obloquy on account of the fatal ſickneſs of Henry prince of Wales, in October 1612; in the treatment of which he differed in opinion from the other phyſicians, with reſpect to the uſe of blood-letting. But his conduct obtained the approbation of the king and council, of which certificates, couched in the moſt ſatisfactory terms, were given him. He received the honour of knighthood from James, in 1624; and on the acceſſion of Charles I. he was appointed firſt phyſician to him and his queen, and roſe to high favour, particularly with the latter. During the civil commotions he ſtill adhered to the royal party, for he was appointed firſt phyſician to Charles II. after the death of his father, although the office was now merely nominal. Thus he enjoyed the extraordinary honour of ſerving four kings ſucceſſively in his medical capacity; and during all this period he was moſt extenſively employed by perſons of the firſt rank in this kingdom, by which he accumulated a large fortune. He died at Chelſea, March 15, 1655, in the eighty-ſecond year of his age, and was buried in the church of St. Martin's-in-the-Fields. Sir Theodore was twice married; but left only one daughter, who was married to the marquis de Cugnac, grandſon of marſhal de la Force. He bequeathed his library to the College of Phyſicians.

The only work which ſir Theodore Mayerne publiſhed himſelf, was the "Apologia," before-mentioned. But in Germany a letter of his was printed in 1619, "De Gonorrheæ inveteratæ, et Carunculæ et Ulceris in meatu urinario curatione ad Geo. Mat. Koningium." After his death were publiſhed "Medical Counſels and Advices," and "A Treatiſe on the Gout," which had been written in French, tranſlated into Latin by Theoph. Bonetus, and thence into Engliſh by Dr. Thomas Sherley, in 1676. Alſo, "Praxeos Mayernianæ in Morbis internis gravioribus et chronicis Syntagma," publiſhed in 1690, by his godſon, ſir Theodore de Vaux, who alſo communicated to the Royal Society, in 1687, "Mayerne's Account of the Diſeaſes of Dogs, with ſeveral Receipts for Canine Madneſs," printed in the Philoſophical Tranſactions for that year. "Tractatus de cura Gravidarum," added to an edition of the "Praxis." Moſt of theſe were included in Dr. Joſeph Browne's publication, entitled "Mayernii Opera Medica, complectentia Conſilia, Epiſtolas, et Obſervationes, Pharmacopeiam variaſque Medicamentorum formulas," folio, 1701. The firſt book in this volume conſiſts of medical caſes treated by the author, to moſt of which the names of the patients are prefixed, who are in general perſons of the firſt quality in France and England. They comprehend a ſeries from 1605 to 1640. The deſcriptions are generally diſtinct, minute, and judicious, and the reaſonings, though commonly founded upon the erroneous doctrines of that time, are yet acute and learned. His preſcriptions are moſtly of the compound form of the Galenical ſchool; yet his Pharmacopeia exhibits a number of chemical preparations, and he, doubtleſs, contributed much to their introduction. Nor did he confine his chemical knowledge to medicinal ſubjects; for he is ſaid to have diſcovered, by a courſe of experiments, the principal colours to be uſed in enamelling, and to have communicated them to Petitot, the famous painter in that branch. He was, likewiſe, converſant with natural hiſtory, and edited Mouffet's poſthumous "Theatrum Inſectorum." Aikin's Biog. Memoirs of Med. Gen. Biog.

MAYET, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the diſtrict of La Flèche; 15 miles S. of Le Mans. The place contains 3165, and the canton 10,049 inhabitants, on a territory of 210 kiliometres, in ſeven communes.

MAYET-*de-Montagne, Le*, a town of France, in the department of the Allier, and chief place of a canton, in the diſtrict of La Paliſſe; 10 miles S.E. of Cuſſet. The place contains 3945, and the canton 14,443 inhabitants, on a territory of 180 kiliometres, in 12 communes.

MAYETA, in *Botany*, Aubl. Guian. 443. t. 176. Juſſ. 330; is *Melaſtoma Maieta*, Lamarck Dict. v. 4. 34. Willd. Sp. Pl. v. 2. 589. See MELASTOMA.

MAYFIELD, in *Geography*, a townſhip of America, in Montgomery county, New York, incorporated in 1793, and containing 876 inhabitants.

MAYHEM. See MAHIM.

MAYHEM, *Appeal of*. See APPEAL.

MAYL, in *Falconry*, ſignifies to pinion the wings of a hawk.

MAYLLO, in *Geography*, a town of Spain, in the province of Leon; 14 miles E.S.E. of Ciudad Rodrigo.

MAYNA, in *Botany*, (why ſo called does not appear,) Aubl. Guian. 921. t. 352, a diœcious ſhrub, of which the male only was obſerved in Cayenne by Aublet. He deſcribes it by the name of *M. odorata*, as having ſeveral upright, ſimple, flexible, brittle *ſtems*, about ſix feet high. *Leaves* alternate, ſtalked, ten inches long, and three wide, lanceolate inclining to obovate, pointed, entire, ſomewhat wavy, of a fine ſhining green, and a firm texture, with a prominent rib and numerous veins beneath. *Stipulas* lanceolate, deciduous. *Flowers* axillary, ſeveral together, on ſhort ſtalks, white, and very agreeably ſcented, produced in the month of December. The *calyx* is in three deep concave ſegments, externally hairy. *Petals* eight, roundiſh, with ſhort erect claws. *Stamens* 28 or 30, diſpoſed upon a conical receptacle; their filaments ſhort, anthers long and quadrangular, opening at the top. Aublet could find no traces of a piſtil, nor could he diſcover the female plant, though he carefully ſought for it. Juſſieu has juſtly referred this genus to his order of *Magnoliæ;* ſee that article.

MAYNARD, FRANCIS, in *Biography*, a French poet, born in 1582, was ſon of a counſellor in the parliament of Toulouſe. He was introduced, while very young, to court, and was appointed ſecretary to queen Margaret. In 1634, the duke de Noailles, being appointed ambaſſador to the court of Rome, took Maynard with him. He was member of the French Academy from its firſt inſtitution, and endeavoured to ingratiate himſelf with the cardinal Richelieu, but failing in his object, he gave him the appellation of tyrant, and wrote ſatires upon him. At length, weary in the purſuit of fortune, he retired to his native province, where he died in 1646, at the age of ſixty-four. His works conſiſt of Songs, Epigrams, Odes, Miſcellaneous Poems, and Letters in proſe. They muſt be read with caution, for though eſteemed as a man of honour and a ſincere friend, his principles were very licentious. Moreri.

MAYNARD,

MAYNARD, *Sir* JOHN, an eminent English lawyer, who diftinguifhed himfelf by his patriotifm, as well as his knowledge of jurifprudence, and integrity in his profeffion. When the prince of Orange was declared king after the abdication of James II., fir John waited upon the new monarch with an addrefs; and William having obferved to him that from his age he muft have outlived moft of the judges and eminent lawyers of his ftanding; he replied, "and I fhould have outlived the law too had it not been for the arrival of your majefty." He died in 1690, aged 88. Biog. Brit.

MAYNAS, in *Geography*, a government of South America, in the eaftern limit of the audience of Quito, lying contiguous to thofe of Quixos and Jaen de Bracamoros towards the eaft. In the territories of this jurifdiction are the fources of thofe rivers, which form by their conflux the Maranon. The ftreams of thefe rivers environ and pervade the government of Maynas. Its limits, both towards the N. and S., are little known. Eaftward it joins the poffeffions of the Portuguefe, from which it is feparated by the line of demarcation that forms a boundary between the Spanifh and Portuguefe poffeffions. Santiago de la Laguna, which is the refidence of the governor, is properly the capital of Maynas; though San Francifco de Borja has been ufually confidered as fuch. (See COCAMA.) The miffionary villages of this jurifdiction are numerous; and they trade with each other, and alfo with Quito and Lamas, in falted fifh, chocolate, of which the arroba (25 lbs.) is fold for two rials, wax, yuca, and vegetable candles, called by the natives "paltas," being the fruit of a tree, which, when lighted, prefents at once wax and wick. Whether this tree be the "croton febifera" of Linnæus has not been afcertained. There are alfo fome poor manufactures, chiefly cloaks and hats, made of the rich plumage of the birds, with which they are formed after any pattern. The manners and cuftoms of the inhabitants of Maynas differ little from the other nations of the Pampas del Sacramento, except where they are tinged with a faint dye of Chriftianity.

MAYNBERNHEIM, a town of Germany, in the margraviate of Anfpach, near the Maine; 12 miles S.E. of Wurzburg.

MAYNE. See MAYENNE.

MAYNE, a river of Ireland, in the county of Antrim, which, rifing towards the centre of the county, flows into lough Neagh, a little below Randalftown.

MAYNOOTH, a poft-town of Ireland, in the county of Kildare, and province of Leinfter. In this town is the Royal College of St. Patrick, for the education of perfons profeffing the Roman Catholic religion, inftituted by act of parliament in the year 1795. The building confifts of lodging-rooms, fchools, a church, library, hall, and different offices fuitable to the accommodation of 200 ecclefiaftical ftudents, befides profeffors, officers, and fervants. There is alfo a Lay College, eftablifhed by private fubfcription in 1802. When the evils attendant on a foreign education, efpecially under the circumftances in which the Roman Catholic clergy of Ireland were educated, at the expence of foreign powers, are confidered, it muft be admitted to have been a wife ftep in the parliament of Ireland to provide a place of education for them at home; and it is furprifing that the expence thus incurred fhould ever be objected to by Proteftants. The queftion is not, whether the tenets of popery are deferving of fupport? but whether the population of Ireland is to be fupplied with priefts educated at the expence, and of courfe attached to the intereft, of foreign powers, or fupplied with them from a college fupported at the national expence? Maynooth had formerly a college, founded in 1518 by an earl of Kildare, whofe defcendent, the duke of Leinfter, has a princely refidence in the neighbourhood. It has alfo a charter-fchool for fifty girls. Maynooth is 12 miles W. by N. from Dublin.

MAYO, a county of Ireland, in the province of Connaught, the third in fize, but one of the leaft populous in proportion to its extent. It is bounded on the N. and W. by the Atlantic ocean, on the E. by Sligo and Rofcommon, and on the S. by Galway. Its length, from N. to S., is 49 Irifh or 62 Englifh miles; and its breadth 45 Irifh or 57 Englifh miles. It contains 790,600 acres, or 1235 fquare miles Irifh, equal to 1,270,144 acres, or 1984 fquare miles Englifh. Its population was eftimated, when Dr. Beaufort wrote, at 140 000, but there muft have been fince that time a confiderable increafe in this as well as every other county. There are 68 parifhes, but thefe are combined into eighteen benefices, having about as many churches, which would be a dreadful grievance, if the great mafs of the people were not Roman Catholics. The foil of the county of Mayo varies prodigioufly, from the bleak and rugged mountain to the fertile and chearful plain. The eaftern and fouthern parts are arable and champaign, and though not arrived at a high degree of cultivation, they produce a fufficiency of corn and flax for home confumption, and fupply other counties with abundance of fat and ftore cattle. In the mountainous diftrict of Burrifhoole there are fome fruitful grounds along the coaft and in the vallies. But a large extent in the N.W. is overfpread with an immenfe mafs of uninhabited mountains, and tractlefs bogs without roads, and very difficult of accefs to the few farmers and fifhermen who dwell upon the coaft, and to the inhabitants of the Mullet; a peninfula, which is faid to be fertile, pleafant, and well inhabited. Among the mountains in the S.W. Croagh-Patrick claims the pre-eminence, the conic fummit of which is diftinguifhed at a vaft diftance rifing 2666 feet above the level of the fea, and being by fome efteemed the higheft mountain in Ireland, but others confider the Recks in Kerry to furpafs it. On the top of Croagh-Patrick is a very large and remarkable cairn. M'Nephin, though little inferior to it in height and fublimity, being 2640 feet high, is of a very different character, for it ftands almoft infulated, and appears rounded on all fides, and at top like a huge rath or barrow. There are, in the flat country that borders upon the lakes of Mafk and Carrah, many miles of rocky ground, which, at a diftance, appear like one immenfe fheet of white ftone. But upon a nearer infpection of thefe fingular rocks, they are perceived to ftand in parallel lines, from one to three feet above the furface, like flag-ftones pitched in the ground upon their edges; and however they may vary in fhape, fize, and diftance, they are all calcareous, and have all the fame direction. Fiffures of a great depth are found in fome of the narroweft interftices; but, in general, the verdure between them is beautiful, and the pafture excellent for fheep. Large caverns and fubterraneous waters are alfo frequent in this part of the country, efpecially near Cong. At the back of that fmall village, a very broad river rufhes at once from beneath a gently-floping bank, and after a rapid courfe of about a mile, lofes itfelf in lough Corrib. It is fuppofed to be the outlet of a fubterraneous channel, through which the fuperfluous waters of lough Mafk and lough Carra are difcharged into Corrib. This rocky part of Mayo abounds alfo with *turlachs*, as they are called in Irifh. Thefe are plains, fome of them very extenfive, which having no vifible communication with any brooks or rivers, in the winter are covered with water, and become in the fummer a rich and firm pafture, the waters rifing and retiring through

rocky

rocky clefts in the bottoms. There are many fine lakes in this county. Lough Conn, at the foot of M'Nephin, is nine miles long; lough Mask is longer by two miles, and considerably broader. There are some fine harbours, and many islands, the most remarkable of which are noticed in distinct articles. Castlebar is the county town. The only members of parliament returned from this county are the two knights of the shire. Beaufort's Memoir.

MAYO, or *May*, one of the Cape de Verd islands, about 21 miles in circumference, of an oval form, with a variety of rocks and points projecting into the sea. Its elevation above the sea is considerable; nevertheless its surface is level and plain, if we except two mountains of considerable height. The shore, according to the description of Dampier, presents sandy bays between the promontories, which afford good anchorage. On the W. side of the island, are a bay of this kind, where ships drop anchor, and a sand bank, forty paces wide, and extending nearly three miles along the shore, within which is a large salt pond, two miles long, and half a mile broad, from the N. end of which salt is obtained in the whole dry season, that is, from November to the month of May. The soil of the island is dry, with little moisture from rivulets or springs, its humidity being occasioned by the nightly dews, or the showers that fall in the wet season. In the whole island there is only one spring, near its centre, the water of which runs off in a small stream through a valley confined by the hills. The island of course must be in a very considerable degree barren and unproductive. It has three small towns, which contain all the inhabitants of the island. The chief fruits are figs, water-melons, citrons and oranges of a very indifferent quality, and pumpions, which, together with calwanas, a sort of bean, furnish the natives with their ordinary diet. The sea supplies great variety and plenty of fish. The number of inhabitants is estimated at 7000. N. lat 15° 10′. W. long. 23° 8′.

MAYO, a river of New Mexico, which runs into the gulf of California, N. lat. 27° 40′.—Also, a town of South America, in the government of Caraccas; 35 miles W. of Caraccas.—Also, a province of New Mexico, bounded on the N. by the province of Hisqui, on the E. by New Biscay, on the S. by Cinaloa, and on the W. by the gulf of California.

MAYOBAMBA, a town of Peru, in the diocese of Truxillo. S. lat. 6° 58′.

MAYOMBA, or JAMBO, a town of Africa, in Loango, on the coast. S. lat. 3° 45′. E. long. 10° 24′.

MAYOMBO, a town of Congo; eight miles S.S.W. of Bombi.

MAYOR, a small island in the South Pacific ocean, near the coast of New Zealand. S. lat. 36° 57′. E. long. 183° 31′. Near this is a cluster of small islands and rocks, to which Cook gave the name of "The Court of Aldermen."

MAYOR, *Cape*, a cape on the N. coast of Spain. N. lat. 43° 29′. W. long. 3° 46′.

MAYOR, or *Maior*, the chief magistrate or governor in the cities, and most corporation towns of England; chosen annually by his peers out of the number of the aldermen. See ALDERMAN.

The word, according to Verstegan, comes from the ancient English *maier, able, potent*, of the verb *may*, or *can*. The mayor of the place is the king's lieutenant, and, with the aldermen and common-council, can make laws, called *bye-laws*, for the government of the place. He has also the authority of a kind of judge, to determine matters, and to mitigate the rigour of the law.

King Richard I., A.D. 1189, first changed the bailiffs of London into mayors; by whose example others were afterwards appointed. See LONDON.

Mayors of corporations are justices of peace *pro tempore*, and they are mentioned in several statutes; but no person shall bear any office of magistracy concerning the government of any town, corporation, &c. that hath not received the sacrament, according to the church of England, within one year before his election; and who shall not take the oaths of supremacy, &c. stat. 13 Car. II. cap. i.

MAYOR'*s-Court*. See COURT.

MAYORGA, in *Geography*, a town of Portugal, in Estramadura, on the W. coast, near the Atlantic; 50 miles N. of Lisbon.—Also, a cluster of small islands in the South Pacific ocean, discovered in 1780 by don Francisco Antonio Maurelle. S. lat. 18° 38′. E. long. 179° 52′.

MAYORGA *Island*. See MAJORCA.

MAYOTTA, the most southerly of the Comorra islands, about 240 miles from the coast of Africa, and 150 from the island of Madagascar. Although this island is cold, low, and damp, and not inhabited near the coast, it abounds with provisions and fruits. S. lat. 13°. E. long. 45° 16′.

MAYOW, JOHN, in *Biography*, an ingenious physician and physiologist, was born in Cornwall in 1645. He was educated at Oxford, where he became a probationer fellow of All-Souls' college, having first been entered a student of Wadham. He took a degree in civil law, but afterwards studied medicine, and entered upon the practice of that profession. He seems to have resided chiefly at Bath; but died at the house of an apothecary in York-street, Covent-garden, in the year 1679.

These are all the brief memoirs that are recorded of a man, who went before his age in his views of chemical physiology, and in some measure anticipated, darkly and imperfectly it is true, some of the most remarkable discoveries in pneumatic chemistry, which the present age has produced. He published at Oxford, in 1699, "Tractatus duo, quorum prior agit de Respiratione, alter de Rachitide." These were afterwards reprinted, in 1674, with three additional dissertations, under the title of "Tractatus quinque Physico-Medici, quorum primus agit de Sale Nitro, et Spiritu Nitro-äereo, secundus de Respiratione, tertius de Respiratione fœtûs in utero et ovo, quartus de motu musculari et spiritibus animalibus, ultimus de Rachitide." It is from the first of these treatises, on nitre and nitro-aërial spirit, that Mayow derives his claim to the originality of discovery just alluded to. His nitro-aërial or igneo-aërial spirit, the existence of which he proves by many ingenious and decisive experiments, is a constituent part of the atmospherical air, and the food of life and flame, and is the same with the oxygen, or vital air, of the modern chemists, which has become so important an object in chemical philosophy. His speculations about it are indeed mixed with much of the absurd hypothesis of the times; but some of his ideas relative to its agency nearly accord with the more recent doctrines; especially that of its absorption by the blood in the lungs, during respiration, and the production of animal heat by its means. He also anticipated the mode of operating with aërial fluids, in vessels inverted over water, and the method of transferring them from one vessel to another, under this fluid. In a word, had he lived at a later period, and possessed the lights of his successors, he would in all probability have been a distinguished improver of his science and profession. His theory of the nitro-aërial spirit runs through all his hypotheses, and he regards it as the cause of muscular motion and of the nervous energy; in which respect, he still more nearly approached some of our own contemporaries in his views of this spirit,

ſpirit. Dr. Beddoes republiſhed his chemical tracts in 1790, with a view of ſhewing his claim to ſome ſhare of the credit which has been awarded to modern diſcoverers. Gen. Biog. Eloy.

MAYPO, in *Geography*, a river of Chili, which runs into the Pacific ocean, N. lat. 33° 26′.

MAYRI, a town of Cuba; 25 miles S. of Havanna.

MAYS, in *Botany*. See ZEA. This name, which we uſually write Maize, ſeems to be an Indian word, and was introduced along with the plant which bears it, otherwiſe called Indian wheat, at the very earlieſt period of the introduction of exotic plants into Europe. Maize appears, by Turner's herbal, to have been cultivated here in 1562, and was probably brought much earlier from the eaſt.

MAYSVILLE, in *Geography*, a poſt-town of America, in Maſon county, Kentucky; 484 miles from Waſhington.

MAYTENUS, in *Botany*, a barbarous word, formed of the Chili name *Maiten*. Molin. Chil. 152. Vahl. Enum. v. 1. 304. Juſſ. 449.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Jaſmineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, very ſmall, of one leaf, five-lobed. *Cor.* of one petal, bell-ſhaped, undivided. *Stam.* Filaments two, inſerted into the corolla; anthers .... *Piſt.* Germen ſuperior, roundiſh; ſtyle undivided; ſtigma ſimple. *Peric.* Capſule ſmall, ovate, compreſſed, of two cells and two valves, burſting at the edges, the partitions continued half way along the middle of the valves, which are at length reflexed. *Seeds* ſolitary, ovate-oblong, attached to the bottom of each cell; embryo flat, in a fleſhy albumen.

Eff. Ch. Calyx five-lobed. Corolla bell-ſhaped, undivided. Capſule ſuperior, compreſſed, of two cells and two valves. Seeds ſolitary.

1. M. *boaria*. (Maiten; Feuill. Chil. v. 3. 39. t. 27.) Native of Chili. A *ſhrub* or ſmall *tree*, with the habit of a *Phillyrea*. About twenty feet high, much branched. *Leaves* ſometimes oppoſite, ſometimes alternate, evergreen, nearly ſeſſile, elliptical, acute, ſerrated, ſmooth; dark green above, brighter beneath; with a prominent rib, and ſeveral veins. The *flowers*, which Feuillée did not meet with, are deſcribed by Juſſieu as ſcattered. The laſt-mentioned author ſays one cell of the fruit, with its ſeed, is frequently abortive. He errs in ſuppoſing the genus akin to Forſter's *Bankſia*, which is the *Pimelea* of later writers, and belongs to the order of *Thymelææ*.

"The *Maiten*," ſays Feuillée, "is the counter-poiſon of the *Llithi*," (Feuill. Chil. v. 3. 33. t. 23, a plant whoſe claſs and genus are unknown to us), "the meer ſhade of which cauſes ſuch ſwellings as to deform the human body. In caſe of ſimilar accidents, a decoction of the branches of the *Maiten*, uſed as a fomentation to the parts afflicted, is the moſt ſpeedy cure."

MAYTO, in *Geography*, a town of Mexico, in the province of Xaliſco; 50 miles W.N.W. of Purification.

MAYTZ, a town of Pruſſia, in the province of Bartenland; 18 miles S. of Raſtenburg.

MAYZE, CAPE, or *Cape Maizo*, the eaſtern point of the iſland of Cuba. N. lat. 20° 18′. W. long. 74° 10′.

MAZA, a name given by the ancients to a ſort of food, in common uſe among the poorer ſort of people. It is made of the meal of parched barley, ſprinkled with ſome liquid, and was eaten with honey, or with defrutum.

Hippocrates every where ſpeaks of this as of a coarſe kind of bread, and adviſes the changing the common finer bread, in the ſpring ſeaſon, for this coarſer kind, as a thing very conducive to health. He ſeems every where to conſider bread as the drier, and maza the moiſter diet.

MAZA, Μάζα, among the Athenians, a ſort of cake, which was the common fare of ſuch as were entertained at the public expence in the common-hall, or *prytaneum*.

Theſe cakes were made with flour boiled with water and oil. Pitiſc. Lex. Ant. in voc.

MAZACA, in *Ancient Geography*, a town of Cappadocia, in the prefecture of Cilicia, called alſo Maza, and ſurnamed Cæſarea. Strabo gives it the title of metropolis of Cappadocia, ſurnamed Euſebia, and places it on mount Argæus.

MAZAGAN, in *Geography*, a town of Africa, in the empire of Morocco; 4 leagues S. Azamore, built by the Portugueſe in 1506, and named by them "Caſtillo Real." Under the walls of this town a dock has been made, which will admit ſmall veſſels; but large ſhips are obliged to anchor two leagues out at ſea, on account of the cape of Azamore, which ſtretches to the W., and which it would be difficult to double, if a S.W. wind ſhould drive them from their anchors. This town remained in the poſſeſſion of the Portugueſe till the year 1769, when the emperor of Morocco laid ſiege to it juſt as it was about to be abandoned by its former maſters. It is at preſent entirely ruined, and almoſt uninhabited. At a little diſtance to the S.W. of Mazagan is an old tower, called Boriſha, whence is derived the name of Bridja, which the Moors confound with that of Mazagan; 61 miles N. of Morocco. N. lat. 32° 54′. W. long. 8° 46′. Chenier's State of Morocco, vol. i.

MAZALIG, a town of Africa, in the country of Sugulmeſſa; 50 miles N.E. of Sugulmeſſa.

MAZAMET, a town of France, in the department of the Tarn, and chief place of a canton, in the diſtrict of Caſtres; 9 miles S.E. of Caſtres. The place contains 5474, and the canton 12,410 inhabitants, on a territory of $257\frac{1}{2}$ kiliometres, in 11 communes.

MAZANDERAN, or MAZENDRAN, a province of Perſia, ſituated along the ſouthern coaſt of the Caſpian ſea, and bounded on the E. by Khoraſan, encircled on the S. by a lofty branch of the Caucaſian chain, which was the ſeat of the Mardi of antiquity, and on the W. by Ghilan. The ſouthern part is mountainous, and nearly deſert, interſperſed with ſome pleaſant vallies, and enjoying a ſalubrious air: this part is called Taberiſtan. Towards the north this province is extremely fertile, inſomuch that it is called the "Garden of Perſia," and from September to April, the whole country appears like a vaſt parterre of flowers. The chief productions are ſilk, far inferior to that of Ghilan, rice and cotton, of which articles there is a large exportation. The cotton the inhabitants dye and manufacture. The province alſo affords ſugar, excellent fruit, eſpecially raiſins, of ſome of which they make wine, but the greateſt part is dried for ſale, corn, and ſalt. Among the animals are tygers, deer, ſheep, goats, &c. Mazanderan is well ſituated for trade on the Caſpian ſea; but the coaſts are much infeſted by pirates. The capital is Fahrabad, or *Farabat*, which ſee. This province, and alſo thoſe of Shirvan, Ghilan, and *Aſtrabad*, (which ſee,) are much affected by the unſettled ſtate of Perſia, and the civil wars which continue to haraſs that divided empire. On the death of Kerim Khan, the ſucceſſor of Nadir Shah, in 1779, Perſia became expoſed to all the horrors of a diſputed ſucceſſion, and was divided between the two principal competitors. Akau Mahomed Khan, a Perſian of high diſtinction, was caſtrated in his infancy by order of Nadir Shah, but poſſeſſing great civil and military talents, he became maſter, in 1788, of Mazanderan and Ghilan, as well

as

as the cities of Iſpahan and Tauris. Jaafar Khan, nephew of Kerim Khan, was at that period ſovereign of Shirauz, the capital, and of the ſouthern provinces. In general, however, theſe provinces are governed by their own khans, who, though tributary to the ſophy, render themſelves occaſionally independent; and as they are continually at war with each other, their governments are almoſt always the ſeat of hoſtility, rapine, and devaſtation; and the trade flouriſhes or declines in proportion as the exactions of the ſovereigns are more or leſs frequent and exorbitant.

MAZANO, a town of Italy, in the Veroneſe; 8 miles N. of Verona.

MAZARA, a ſea-port town of Sicily, in the valley of Mazara, ſituated on the S.W. coaſt, near a river of the ſame name, near or upon the ruins of Selinuntium. At a diſtance its appearance is not unpromiſing, as it preſents to view ſeveral convents and chapels richly ornamented; but its ſtreets are narrow and winding, and it has only one ſquare before the cathedral. Mazaran was of ſome note in the time of the Romans, and many of their tombs and inſcriptions are found in it. In the cathedral are ſome valuable ſarcophagi, and one in particular, which, on account of the ſtyle of its compoſition, as well as its deſign and workmanſhip, is attributed to the Greeks. Mazaran was laid waſte by the Saracens, and was taken from them by earl Roger, who vowed to build a church if he obtained a victory. The church does not now exiſt. At Mazara have been found ſome Punic, and many Roman coins, and thoſe of the Saracens in their tombs. It has not now more than 7000 inhabitants, without trade or manufacture. The chief cultivation is that of cotton. Here is no harbour, but the ſea enters by a channel above half a mile into the country, which would form an excellent ſhelter for ſhipping, if merchants had any inducement to come hither. Mazara is the ſee of a biſhop; 50 miles S.W. from Palermo. N. lat. 37° 46′. E. long. 12° 28′.

MAZARELLI, a town of Sicily, in the valley of Noto; 15 miles S.W. of Noto.

MAZARIN, Julius, in *Biography*, cardinal, and a celebrated miniſter of ſtate, was born in 1602, at Piſcina, in Italy, of a noble family named "Mazarini." In the courſe of his education he was diſtinguiſhed for his talents, and was introduced into the houſhold of Jerome Colonna, afterwards cardinal. He followed that nobleman into Spain, where he ſtudied the law, and on his return he took the degree of doctor. He frequented the court of Rome, and attached himſelf to Sachetti, as he did afterwards to cardinal Barberini, to whom he afforded much aſſiſtance in his attempts to effect an accommodation between the different powers. When the French were juſt preparing to attack the Spaniſh lines before Caſal, Mazarin rode out of them, exclaiming "Peace, Peace," and brought propoſals to the French general, which cauſed a ſuſpenſion of arms, which was followed by the treaty in 1631. His ſervice was rewarded by the pope with a place, and in 1634 he was ſent as vice-legate to Avignon, and nuncio to the court of France. He there acquired the eſteem of Richelieu, and of the king, Lewis XIII., who procured for him a cardinal's hat: and after the death of Richelieu, the monarch created him counſellor of ſtate, and one of the executors of his will. At the death of Lewis, in 1643, Mazarin was immediately placed at the head of the government by the regent queen Anne of Auſtria, who had the moſt unbounded confidence in him: he was a very different man from Richelieu; he was ſimple and modeſt in his appearance and equipage; inſinuating in his manners and he ever affected to carry his points rather by gentle means than by the force of authority. The rapacity of his diſpoſition ſoon raiſed a powerful party againſt him, while his foreign manners threw a ridicule over him which rendered him contemptible. Some edicts of taxation being refuſed verification by the parliament of Paris, Mazarin cauſed the preſident Blancmeſnil, and the counſellor Brouſſel to be impriſoned. This was the ſignal for the civil wars which commenced in 1648, in which the Pariſians were excited to revolt by De Retz, with ſeveral princes of the blood and nobles. The queen, the young king, and the miniſter, were obliged to take refuge at St. Germain. Mazarin was proſcribed as a public diſturber of the peace: Condé, then on the ſide of the court, beſieged Paris, and the "war of the Fronde" enſued, which was more fertile in ſatirical ſongs and epigrams, than in important events. An accommodation was effected in 1649; by which the parliament preſerved its right of aſſembling, and the queen kept her miniſter. In the following year, freſh diſturbances led the parliament to iſſue a decree, baniſhing Mazarin from the kingdom. He made his retreat to Cologne, whence he continued to govern the kingdom by his counſels. In 1652 Mazarin returned to France with 7000 men whom he had raiſed, but being regarded by parliament as a public enemy, he was obliged a ſecond time to retire. In 1653 he entered Paris amidſt the acclamations of the inconſtant people, and even the parliament, from which a more ſteady line of conduct might have been expected, received him with diſtinguiſhed honours. Henceforward his powers were unlimited: in 1655 he made a treaty with Cromwell, of which one of the conditions was the refuſing Charles II. an aſylum in France. The war with Spain was terminated in 1659, by the peace of the Pyrenées, negotiated in perſon between Mazarin and the Spaniſh prime miniſter. The ceſſion of Alſace to France was one of its conditions, and the marriage of the young king to the infanta of Spain was another. After this the cardinal aſſumed a greater ſtate, and ruled with a more abſolute ſway; while the queen-mother loſt all her influence, and was reduced to inſignificance. Hiſtory has handed down a variety of heavy charges againſt him; ſuch as having purpoſely brought up the young king in ignorance, not having ſignalized his adminiſtration by a ſingle grand or uſeful national eſtabliſhment; and having amaſſed ſuch a fortune as no other miniſter ever had, amounting, it was ſaid, to two hundred millions of livres, or eight millions ſterling. His proſperity was of no long duration: he was attacked by a diſeaſe which his conſtitution could not reſiſt. When ſenſible of his danger he began to feel ſcruples concerning the wealth which he had heaped together, and his confeſſor plainly told him that reſtitution was neceſſary for his ſalvation. He gave the whole to the king, in the hope that, as was the caſe, his majeſty would reſtore it to him. He died in 1661, at the age of fifty-nine. The letters of cardinal Mazarin, containing his negociations at the peace of the Pyrenées, were publiſhed in two volumes 12mo. in 1745. The tracts on the controverſy reſpecting the war of Fronde were ſo numerous, that a complete collection of them amounted to forty-ſix volumes 4to. The adminiſtration and talents of Mazarin have been compared with thoſe of Richelieu, but the commanding features which diſtinguiſhed the latter are in vain ſought for in the former. Prudent, ſubtle, and avaricious, he endeavoured to ſoothe rather than command; to deceive than to vanquiſh; and the love of glory either did not exiſt in his boſom, or was loſt in his inſatiable thirſt of money. Moreri. Hiſt. of France. 1790.

MAZARINA, in *Geography*, a town of Sicily, in the valley of Noto; 20 miles N.E. of Alicata.

MAZATLAN, a town of Mexico, in the province of Chiametlan, on a river of the fame name, which runs into the Pacific ocean; 40 miles N.W. of Chiametlan. N. lat. 23° 15′. W. long. 106° 46′.

MAZE, in *Gardening*. See Labyrinth.

MAZEAS, John-Mathuirin, in *Biography*, a mathematician, was born at Landernau, in Brittany, in 1713, and died in 1802. He wrote Elements of Arithmetic, Algebra, and Geometry, with an Introduction to Conic Sections; he was alfo the author of "Inftitutiones Philofophicæ," three vols. 12mo. He was an ecclefiaftic, and held a canonry in the church of Notre Dame, at Paris, before the Revolution. Nouv. Dict. Hift.

MAZERAY, in *Geography*, a town of Perfia, in Khorafan; 100 miles W.S.W. of Naffapour.

MAZEUTOXERON, in *Botany*, Billard. Voy. (Englifh edition), v. 2. 8, and 65. t. 17 and 19. See Corræa.

MAZIERA, or Medjare, in *Geography*, an ifland in the Indian fea, near the E. coaft of Arabia, 60 miles long and 8 wide. N. lat. 20°. E. long. 74°.

MAZIERES, a town of France, in the department of the Two Sevres, and chief place of a canton, in the diftrict of Parthenay. The place contains 605, and the canton 8447 inhabitants, on a territory of 257½ kiliometres, in 12 communes.

MAZIL, a town of the ifland of Cuba; 20 miles W.S.W. of Bayamo.

MAZOCHI, Alexio Symmacho, in *Biography*, an Italian antiquary, was born near Capua in 1684. He acquired in early life an attachment to literature, and became diftinguifhed for his acquirements. He went through a regular courfe of philofophy and theology at Naples, and he afterwards became profeffor of the Greek and Hebrew languages, and obtained fome preferment in the church. He was author of feveral ingenious works, of which the principal was the refult of the difcovery of the ruins of an amphitheatre at Capua: it was entitled "Campani Amphitheatri Titulum, aliafque nonnullas Campanas Infcriptiones Commentarius," 1727. This he afterwards very much enlarged. In 1739 he publifhed an epiftle "De dedicatione fub Afcia," on which he employed much erudition. He publifhed many other antiquarian pieces: as "A Hiftory of the Cathedral of Naples:" "Commentarium in Regii Herculanenfis Mufæi Æneas Tabulas Heraclienfes:" "Spicelegium Biblicum," three vols., of which the two firft relate to the Old Teftament, the laft to the New. He died at Naples in 1771, at the age of 86. He was a man void of ambition, and attached to a fober, ftudious, and retired life. He bequeathed to the poor his library and the little property which he had accumulated. Gen. Biog.

MAZONOMUS, among the *Ancients*, a very large difh, commonly of wood, in which the maza was ferved.

MAZORBO, in *Geography*, one of the iflands in the dogado of Venice, and podeftaria of Torcello, compofed of three fmall iflands, united by bridges. It has two churches.

MAZORMO, a town of the ftate of Venice, on the N. bank of the Po; 22 miles S. of Venice.

MAZOUNAH, a town of Algiers, nearly furrounded by the river Shelliff, and celebrated for its woollen manufacture; 30 miles S. of Muftygannim.

MAZULA, in *Ancient Geography*, the name of two towns in Africa propria, according to Ptolemy. He places one on the coaft, and gives it the title of a colony, and the other a little inland.

Mazulà, in *Geography*, a town of Africa, in Congo, on the coaft; 50 miles S.S.W. of Bombi.—Alfo, a fmall ifland in the Atlantic, near the coaft of Africa. S. lat. 8° 5′.

MAZUR, a fpecies of birds which the Arabian failors efteem very lucky, becaufe it lays its eggs clofe by the feafhore before good weather; fo that when thefe are obferved, they promife themfelves a fafe voyage. They alfo pretend that this bird gives notice to failors, when the fhip approaches any danger, by flying and fluttering up and down.

MAZUS, in *Botany*, fo denominated by Loureiro, from μαζος, *a nipple*, on account of the little ftalked tubercles, which fill up the mouth of the corolla. Loureir. Cochinch. 385. Brown Prod. Nov. Holl. v. 1. 439.—Clafs and order, *Didynamia Angiofpermia*. Nat. Ord. *Perfonatæ*, Linn. *Scrophulariæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, large, bell-fhaped, five-fided, permanent, with five lanceolate, fpreading, nearly equal fegments. *Cor.* ringent; its upper lip pointed, in two lobes, reflexed at their fides; lower longer, in three rounded, inflexed, undivided lobes, and two prominences at its bafe; the throat marked externally with two furrows, and lined with ftalked glands. *Stam.* Filaments four, two of them longer, approaching each other in pairs; anthers oblong, combined. *Pift.* Germen fuperior, roundifh; ftyle thread-fhaped, equal in length to the longer ftamens; ftigma fpatulate, of two fpreading plates. *Peric.* Capfule roundifh, enclofed in the calyx, compreffed, of two cells, and two undivided valves, with partitions from their centre. *Seeds* numerous, ovate, fmall.

Eff. Ch. Calyx bell-fhaped, in five equal fegments. Corolla ringent; upper lip cloven, reflexed at the fides; lower three-lobed, with two fwellings at the bafe. Capfule of two cells, with many feeds. Anthers combined.

1. M. *rugofus*. Lour. (Lindernia japonica; Thunb. Jap. 253? Brown.)—Flowers numerous, in a long clufter.—Native of fields in Cochinchina, where it is called *Rau dáng lóng lá*. An annual *herb*, about fix inches high, branched, and nearly erect. *Leaves* oppofite, ovate, ferrated, rugofe. *Flowers* pale violet, in long loofe clufters.

2. M. *Pumilio*. Brown. Stalks bearing from one to four flowers, fmooth as well as the calyx. Gathered by Mr. Brown in Van Diemen's land. A fmall *herb*. *Leaves* cluftered at the root. *Flower-ftalks* radical, either fimple or racemofe.

We cannot perceive any clear diftinction between this genus and *Mimulus*, to which Mr. Brown allows it is nearly allied. See Mimulus.

MAZZAFERRATA, Gio. Bat., in *Biography*, a mufical compofer, who publifhed at Bologna, in 1677, "Cantate," or "Canzonette da Camera a Voce fola," not very good mufic indeed; but the author feems to have been one of the firft compofers who ufed the technical terms *vivoce*, *largo*, and *ardito*, to indicate the time of the feveral movements. Before that it was done by *moods* at the fide of the clef.

MAZZANTI, Ferdinando, an opera finger in foprano, of great eminence in the bravura ftyle of the middle of the laft century. He fung, when we heard him at Rome in 1770, not only with an exquifite tafte, but was a good mufician, and not a mean performer on the violin. He was not only a reader, but a writer of mufic, having himfelf compofed operas and motets for voices; but trios, quartets, and quintets for violins. He had a great collection of Paleftrina's compofitions, of which he was truly fenfible of the fuperiority to thofe of all other ecclefiaftical compofers of his country, *a capella*, and had made, by way of ftudy, an abridgment of the modulation of that venerable father of facred mufic of the moft pure and reverential ftyle, which he he had digested with great judgment and intelligence. He came to England as a singing-master about the year 1773, and remained here till the time of his death. During the last years of his existence, oppressed with age, infirmities, and poverty, he was reduced to the utmost misery and wretchedness. His temper was not amiable: he was naturally peevish, impatient, and disputatious, so that his sufferings were not diminished by philosophy or resignation. He seems not to have made a friend in this country during more than thirty years residence, except La Blancherie, who solicited those who had been long laid under contributions for himself, to extend their benevolence to Mazzanti, and for a certain time procured him succour; but subscriptions and collections at length failing, and having no possessions left that were convertible to money or food, except his favourite violin, which he brought from Italy, he reluctantly permitted his sole friend, Blancherie, to negociate a raffle for it, at half a guinea a ticket, and in a short time the requisite number being disposed of, chiefly to musical professors, on Saturday, May 11th, 1805, the raffle took place at Menzani's music shop, when the blind and capricious goddess, Fortune, for once, seems to have had a glimmering of light and reason, in throwing her handkerchief at François Cramer, who so well knew the use of the lot with which he was crowned. But, alas! during the conflict of the adventurers for Fortune's favour, the poor mortal who furnished the prize expired!

MAZZARUNI, in *Geography*, a river of Sicily, which runs into the sea, on the S. coast; three miles S.E. of Terranova.

MAZZO, a town of Italy, in the Valteline; nine miles W. of Sondrio.

MAZZOCCHI, DOMENICO and VIRGILIO, in *Biography*, two brothers, the most eminent musicians in Rome during the early part of the seventeenth century. Domenico was a voluminous and excellent composer. He is much celebrated by Kircher, and was almost the last successful madrigalist in Italy, after Luca Marenzio. He seems to have penetrated deeper into latent effects and refinements than his contemporaries. In 1638 he dedicated a set of madrigals, which he published at Rome, to cardinal Barberini. In his dedication, he pronounces madrigals to be "the most ingenious species of composition that music could boast. And yet," he says, "that few were then composed, and still fewer sung; as they were nearly banished from all *academie*, or concerts."

As secular melody was improved by the cultivation of dramatic music, so choral harmony was meliorated by the new combinations that were hazarded in madrigals. And the two Mazzocchi, during this period, contributed greatly, by their numerous works for the church, to improve the more solemn and grave manner of writing for sacred purposes, by extending the bounds of harmony, without which ecclesiastical music could not sustain its dignity, or be suitable to the purposes of its destination. A clear, picturesque, and graceful melody seems infinitely more necessary for the stage than the church; as it is there the voice of passion, and medium through which lyric and narrative poetry can alone be rendered intelligible. In the church, where new poetry, prayers, or sentiments of piety seldom have admission, and where nothing is sung that has not often been previously read and heard by every member of the congregation, the clothing such portions of scripture, or of the liturgy as are appointed to be sung, in rich and complicated harmony, adds greatly to their solemnity, by precluding all such frivolous and fantastical strains as remind the hearer of secular amusements.

Domenico Mazzocchi, besides several new combinations, and a more bold and masterly use of discords in ligature than can be found in the works of his predecessors, if we except Monteverde, first proposed several refinements in the execution of his madrigals, and invented characters of *crescendo*, *diminuendo*, *piano*, *forte*, and the enharmonic sharp. In his eighth madrigal he has made the most frequent use of these new indications. Page 73, there are, indeed, misapplications of the enharmonic diesis to E and B sharp, which is at present rightly appropriated, by the most accurate contrapuntists, to notes that have been already sharp, as a sign of their being still raised a semitone minor. Enharmonic, similar to that of the ancients, we have none, nor is it practicable in modern counterpoint, where, having no fundamental base for quarter tones, their use in harmony would produce no other effect to the hearer than that of singing or playing out of tune.

The only madrigalists after Mazzocchi, who much distinguished themselves, were Stradella, Alessandro Scarlatti, Bononcini, Lotti, Perti, and Caldara, of whom we shall have occasion to speak among the most eminent composers of operas and cantatas.

It seems an indispensable duty to inform the curious reader, that there is a madrigal (*Cor mio*) by this composer, for four sopranos and a contralto voice, inserted in the second part of P. Martini's "Saggio di Contrap," which surpasses in art and ingenuity all the compositions of that kind which we have seen. The expression of the words, and passages of imitation, are still elegant and new. The learned editor has pointed out all its beauties in an excellent commentary.

MAZZOCCHI, VIRGILIO, brother to Domenico, first maestro di cappella to the pope, and master to Bontempi, the musical historian.

MAZZONO, in *Geography*, a town of Naples, in the province of Lavora; seven miles S.W. of Capua.

MAZZUCHELLI, GIAMMARIA, *Count*, in *Biography*, who flourished in the eighteenth century, was distinguished for his acquaintance with Italian literature. He was author of several works, of which we may notice "Notizie Historiche e Critiche intorno alla Vita, alle Inventione, ed agli Scritti di Archimede Siracusano:" "La Vita di Pietro Aretino:" he began a biographical work on the writers of Italy, entitled "Gli Scrittori d'Italia, &c." of which he only finished the two first letters in the alphabet.

MAZZUOLI, FRANCESCO. See PARMEGGIANO.

MAZZUOLI, GIROLAMO, the cousin and pupil of Francesco, is little known as a painter beyond Parma and its districts, though for "impasto," and the whole mystery of colour, he has few equals. There is reason to believe that several pictures painted by this artist, especially those of a higher and gayer tone, are constantly ascribed to Parmeggiano. He was more attached to the style of Corregio than Francesco, and seized its character with great avidity in the nuptials of Santa Catherina in the church del Carmine. He excelled in perspective, and in the Last Supper, in the refectory of Santa Giovanni, placed and painted a colonnade with all the illusions of Pozzo. To the most harmonious chiaroscuro, he added grandeur, variety, and vivacity in fresco. He had a son, Alessandro Mazzuoli, who painted in the dome of Parma 1571. He is a feeble imitator of the family style. Fuseli's Pilkington.

MBACQUA, in *Geography*, a town of South America, in Buenos Ayres; 120 miles E. of Corrientes.

MBOMBOY, a river of Paraguay, which runs into the Parana.

MBOTELEY,

MBOTELEY, a river of Paraguay, which runs into the Parana.

MEACO, or MIACO, called alfo *Kio*, a city of Japan, in the ifland of Niphon, the ancient metropolis of the whole empire, and now the fpiritual capital, being the refidence of the Dairis, and fecond city of the empire, is fituated near the middle of the fouthern coaft, on a fpacious and fertile plain, about 160 miles S.W. from Jedo, the reputed capital. Neverthelefs this is the firft commercial city, and is celebrated for the principal manufactures. It is alfo the feat of the imperial mint, and as the Dairi's court is literary, all books are printed here. It is furrounded at fome diftance by high mountains, much covered with ftately temples, monafteries, burying-places, and pleafure houfes, all of which are adorned with gardens and orchards, and a great variety of verdure, as they are watered by a great number of rivulets which flow from thofe mountains. Thefe ftreams unite in the centre of the city, and there divide it into the Upper and Lower Towns. The whole city, when in its greateft fplendour, appears by its high and ftately walls to have been about 20 miles in length and nine or ten in breadth; to which we may add its fpacious fuburbs, and the imperial palace, which of itfelf is a kind of city, feparated from the reft. The ftreets are narrow, but long and ftraight; and we learn from Kæmpfer, that by an enumeration of the inhabitants in 1674, they amounted to 405,642, of whom 182,070 were males, and 223,572 females, without including the numerous attendants of the Dairi, and probably the children, together with an immenfe number of ftrangers, who refort hither from all parts of the empire. Its temples are numerous, and beyond conception magnificent and fplendid. Although Meaco has fuffered much from pillage, maffacre, and conflagration, it is ftill the grand ftorehoufe of all the manufactures of Japan, and of all foreign as well as domeftic merchandize, and the principal feat of commerce. Here they refine their metals, coin their money, print their books, and carry on all forts of manufactures: here they weave and dye the richeft filks and ftuffs, make and fell the moft beautiful Japan work, porcelain, mufical inftruments, paintings, carvings, all forts of gold, filver, and copper articles, and particularly fteel of the moft excellent quality, and moft curious workmanfhip: they alfo prepare in this place dreffes of all forts for both fexes, which are fit for ufe, and they manufacture a variety of toys and trinkets. In a word, there is no kind of commodity which may not be procured at Meaco, nor any kind of workmanfhip which its artifts will not imitate. N. lat. 35° 24′. E. long. 153° 30′.

MEAD, RICHARD, in *Biography*, a very eminent phyfician, was born at Stepney, "a fmall village near London," as it is called by his biographer, in Auguft, 1673, of which parifh his father, the Rev. Matthew Mead, a Prefbyterian, was one of the two minifters; but had been ejected, for non-conformity, in the year 1662. As he had a handfome patrimony, being defcended from a confiderable family in Buckinghamfhire, he continued to refide in the parifh, (preaching to a numerous congregation of diffenters,) and beftowed a liberal education on his large family, under a private tutor, at home. This little domeftic fchool, however, was broken up in 1683, when Mr. Mead, having been accufed of participating in a plot againft government, thought proper to retire to Holland, leaving Richard, his eleventh child, under the care of Mr. Singleton, an able claffical fcholar, who had been ejected from the office of fecond mafter of Eton fchool as a non-conformift. Richard made great progrefs in his claffical ftudies, which he proceeded to finifh at Utrecht, under the learned Grævius, in 1689. After a refidence of three years at that place, he determined upon the ftudy of phyfic, and went to Leyden, where he attended the lectures of Herman on botany, and of Pitcairn on the theory and practice of medicine. He received much friendly attention from the latter, from whom he imbibed the mathematical principles of that fcience, which were prevalent in his early writings. He then commenced his travels, and vifited the principal cities of Italy, where he graduated in philofophy and phyfic, at Padua, in Auguft 1695. On his return to England, in 1696, he fettled in the very houfe in which he was born, and practifed his profeffion for feveral years with confiderable fuccefs: and, in 1699, he married the daughter of a merchant in London. His firft publication, entitled "A Mechanical Account of Poifons," which contained the refult of many experiments, made with the poifon of the viper, &c. appeared in 1702, and gained him confiderable credit. In fubfequent editions, however, he candidly retracted fome points of his mechanical theory, which more mature obfervation convinced him was inadequate to explain the functions of a living body. Soon after the publication of this treatife, he was elected a member of the Royal Society, of which he was afterwards appointed one of the vice-prefidents by fir Ifaac Newton. In 1703, he was chofen phyfician to St. Thomas's hofpital, when he took up his refidence in Crutched Friars. In 1704, he publifhed his treatife, "De Imperio Solis et Lunæ in Corpore humano, et Morbis inde oriundis," 8vo. Phyficians have always been prone to apply the fafhionable philofophy of their day to the explanation of the phenomena of the animal economy; and in this effay, Mead built his reafoning on the theory of attraction, which Newton had promulgated, attempting to fhew that periodical influences were produced on the living body, as upon the tides of the fea and the atmofphere. In 1707, he received the diploma of doctor of phyfic from the univerfity of Oxford, through the intereft, as is fuppofed, of Dr. Radcliffe, who was not averfe to patronifing a junior of rifing reputation, when he was himfelf declining. In 1711, he removed to Auftin Friars, into the houfe which had been inhabited by Dr. Howe, then deceafed. About the fame time he was appointed by the company of furgeons to read the anatomical lectures in their hall, which he continued to do during fix or feven years with great applaufe. In 1714, his friend and patron, Dr. Radcliffe, died, and Dr. Mead took his houfe, in Bloomfbury-fquare. He was now a fellow of the College of Phyficians, and he had been called into confultation in the laft illnefs of queen Anne, a few days before her death, and pronounced more decifively on her danger than the court phyficians. From this time he feems to have ftood among the firft of the profeffion; and in the beginning of 1715 refigned his office at St. Thomas's hofpital, partly in confequence of his full employment, and partly of the diftance of the hofpital from his refidence.

The occurrence of the plague at Marfeilles, in 1719, occafioned great alarm in London, where the dreadful mortality of 1665 was not forgotten; and by the direction of the lords of the regency, the fecretary of ftate applied to Dr. Mead for his opinion of the nature of the malady, and of the beft means of preventing its introduction into this country. In confequence of this application, he publifhed, in the following year, "A fhort Difcourfe concerning peftilential Contagion, and the Methods to be ufed to prevent it," dedicated to Mr. Craggs, the fecretary of ftate. In this work he decidedly maintained the contagious nature of the plague, which had been queftioned in France, and laid down a plan for the purpofe of cutting off all communication of the

the infection, by quarantine, lazarettoes, and other means of seclusion. This tract passed through no less than seven editions in one year: to the eighth, in 1723, was added a new chapter on the method of cure; and the last, published in 1744, was still farther enlarged: it was translated into Latin by Mattaire, and afterwards by professor Ward.

In the year 1721, Dr. Mead was directed by the prince of Wales (afterwards George II.) to superintend the experiment of inoculating the small-pox in the persons of some criminals, which had been recommended by Mr. and lady M. W. Montague, in consequence of their knowledge of the salubrity of the practice, as performed at Constantinople, and other eastern countries. His report was favourable; so that the example of the practice was immediately set by the royal family, and its general introduction thus accelerated.

As Dr. Mead was ever anxious to support the honour of his profession by his liberal conduct, and by associating with it the character of a friend and patron of learning, so he asserted its dignity in his "Harveian Oration," read before the College in October, 1723, and afterwards published. In this oration he endeavoured to shew, that the profession was exercised by several families of distinction among the Romans; and he annexed to it a dissertation on some coins, which had been struck at Smyrna, in honour of physicians. This publication was the origin of a controversy, which was begun by Dr. Conyers Middleton, and in which Mead was supported by his friend professor Ward, of the Gresham college. Dr. Middleton, perhaps with the greater weight of erudition on his side, undertook to prove the servile condition of the Roman physicians. The controversy was carried on in a manner honourable to both parties; and Dr. Middleton, in a subsequent work on Greek and Egyptian antiquities, spoke of Dr. Mead in terms of great respect. In the same year, Dr. Mead gave an example of the honourable conduct that is due between the members of a liberal profession, in the services which he performed towards Dr. Freind, when the latter physician was committed a prisoner to the Tower, upon the suspicion of being concerned in Atterbury's plot, in consequence of some free observations which had fallen from him in the house of commons. (See the article Freind.) Dr. Mead obtained his liberation in a spirited manner, and paid over to him a considerable sum, received from his patients during his imprisonment.

In 1727, Dr. Mead was appointed physician in ordinary to George II. His professional occupations were now so extensive, that for many years he had no leisure for writing. He had, so early as the year 1712, communicated to Dr. Freind his opinions respecting the importance of purgatives in the secondary fever of small-pox, upon which subject Dr. Freind published a letter in 1719. But it was not till the year 1747, that Dr. Mead printed his treatise "De Variolis et Morbilis," which contains many valuable observations on both these diseases, and also strong recommendations of the practice of inoculation. Both this work and the Letter of Dr. Freind were made the subject of animadversion by Dr. Woodward, (whose skill in pathology appears to have been much inferior to his knowledge of natural history,) in a work entitled "The State of Physic and Diseases, &c." which gave rise to a controversy that engendered considerable acrimony in the two learned advocates for the practice. Dr. Mead subjoined to his treatise, which was written in a pure Latin style, a translation of Rhazes's commentary on the small-pox, into the same language, a copy of which he had obtained from Leyden, through the assistance of his fellow-student, Boerhaave, with whom he had maintained a constant correspondence. It was chiefly through the patronage and interposition of Dr. Mead, that Mr. Sutton's ventilator, for the purpose of cleaning the foul air from ships, was received into the service of the navy, by an order from the admiralty, after a delay of ten years: and he still farther recommended it, by adding to a publication of several tracts that had been written on the subject, in 1749, "A Treatise on the Scurvy," in which he ascribed that fatal disease to moisture combined with putridity.

About this time, as he began to retire in some degree from the fatigues of practice, he employed his leisure in revising his former publications, and in composing others. He published in the year 1749 his "Medicina sacra, seu de Morbis insignioribus qui in Bibliis memorantur," 8vo. The object of this work was to reconcile men's minds to the sacred writings, by shewing that the diseases, mentioned in them, were explicable on natural grounds; and he supported the doctrine of some divines, who maintained especially that the dæmoniacs mentioned in the gospel were only insane, or epileptic persons. His last work was a summary of the experience of his active professional life, which might be deemed a bequest to his medical brethren, and was published in 1751, under the title of "Monita et Præcepta Medica," 8vo. This little volume was almost purely practical, consisting of detached observations on a variety of diseases and medicines, many of which have stood the test of subsequent experience: it was frequently reprinted, and was translated into English.

Soon after this period, the infirmities of age rendered him incapable of exertion, either as a practitioner or an author, and he gradually sunk under increasing debility, until the 16th of February 1754, when he expired, without any visible signs of suffering, in the eighty-first year of his age. He was interred in the Temple church, near his brother Samuel, an eminent counsellor, who died twenty years before him; and a monument was erected to his memory, in Westminster Abbey, by his son. He was twice married, but had issue only by his first wife, of whom four survived him; namely, a son and three daughters. Two of the daughters were married to eminent physicians, sir Edward Wilmot and Dr. Frank Nichols, who were, with himself, physicians to the king. His second wife, who was daughter to sir Rowland Alston, survived him.

The medical character has rarely obtained more respectability than in the person of Dr. Mead. He was not only in high and universal esteem on account of his professional skill, but was the greatest patron of science and polite literature of his time. He maintained a correspondence with the principal literati of Europe; all men of talents found a ready assistance from him in every undertaking; and no foreigner of any learning or taste visited London, without being introduced to Dr. Mead. His ample income was spent in a noble and hospitable way of living, in gratuities to men of science, and the encouragement of learned publications, and in the collection of scarce and valuable books, manuscripts, and literary curiosities, of which no individual of his time, in this kingdom, possessed so choice and ample a collection. Of all his treasures he made the most liberal use; for he not only freely admitted learned men of all countries to see and examine them, but he likewise entertained them at his table, and treated them with singular urbanity; uniting, as his biographer observes, "the magnificence of princes with the pleasures of philosophers."

The whole works of Dr. Mead have frequently been collected and published in various countries of Europe. A French translation of them by Coste, 1774, in two vols. 8vo.

8vo. is efteemed for its numerous notes. See "Authentic Memoirs of the Life of Richard Mead, M. D." 1755. Gen. Biog.

Mead, a wholefome agreeable liquor, prepared of honey and water.

One of the beft methods of preparing mead is as follows: Into twelve gallons of water flip the whites of fix eggs; mixing thefe well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour, and when boiled, add cinnamon, ginger, cloves, mace, and a little rofemary. As foon as it is cold, put a fpoonful of yeaft to it, and tun it up, keeping the veffel filled as it works; when it has done working, ftop it up clofe; and when fine, bottle it off for ufe.

Thorley fays that mead, not inferior to the beft of foreign wines, may be made in the following manner: Put three pounds of the fineft honey to one gallon of water, and two lemon-peels to each gallon; boil it half an hour, well fcummed; then put in, while boiling, lemon-peel: work it with yeaft; then put it in your veffel with the peel, to ftand five or fix months, and bottle it off for ufe. If it is to be kept for feveral years, put four pounds to a gallon of water.

Macquer, in his "Dictionary of Chemiftry," directs to choofe the whiteft, pureft, and beft-tafted honey, and to put it into a kettle with more than its weight of water: a part of this liquor muft be evaporated by boiling, and the liquor fcummed till its confiftence is fuch, that a frefh egg fhall be fupported on its furface, without finking more than half its thicknefs into the liquor; then the liquor is to be ftrained, and poured through a funnel into a barrel; this barrel, which ought not to be nearly full, muft be expofed to heat as equable as poffible, from twenty to twenty-feven or twenty-eight degrees of Reaumur's thermometer, taking care that the bung-hole be flightly covered, but not clofed. The phenomena of the fpirituous fermentation will appear in this liquor, and will fubfift during two or three months, according to the degree of heat; after which they will diminifh and ceafe. During this fermentation, the barrel muft be filled up occafionally with more of the fame kind of liquor of honey, fome of which ought to be kept apart, on purpofe to replace the liquor which flows out of the barrel in froth. When the fermentation ceafes, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well clofed; a year afterwards the mead will be fit to be put into bottles.

Every maker of metheglin or mead for fale fhall take out a licence, for which he fhall pay 1*l.*, and fhall renew the fame annually, on pain of 10*l.* (42 Geo. III. c. 38.) If any maker of metheglin or mead for fale fhall conceal any of it from the view of the guager, he fhall forfeit for every gallon 5*s.* 15 Car. II. c. 11.

MEADIA, in *Botany*, fo called by Catefby, in compliment to Dr. Richard Mead, the celebrated phyfician, who, whatever might be his merit in his profeffion, was not judged by his contemporaries to deferve this botanical honour; and Linnæus therefore did not confirm it. The only work of Dr. Mead's ever mentioned as giving him a claim to fuch diftinction, is his "Mechanical Account of Poifons," in which however there is nothing botanical. Crantz, a petulant critic of Linnæus, affected to oppofe him in this trifling point, faying that "Mead was perhaps more deferving than many others who had obtained fuch honours." If this be all that can be faid for him, the matter may remain at reft. See Dodecatheon.

Meadia, in *Geography*, a town of Hungary, in the bannat of Temefvar, on a fmall river which runs into the Danube; 52 miles S.E. of Temefvar. N. lat. 45° 10'. E. long. 21° 59'.

MEADOW, in *Agriculture*, a name generally applied to fuch natural grafs lands as are annually mown for hay; but more particularly to thofe which are fo low in their fituations as to be too moift for cattle to graze upon in winter, without breaking the fward, or poaching the furface, which would be highly injurious.

Meadows, from their being generally enriched with the fine mould wafhed down from the adjacent rifing grounds, are ufually of a good foil, and feldom require much other improvement than the removing of temporary imperfections, and the fuperabundant moifture by proper draining. But they may be of fuch a nature as to ftand in need of a more particular treatment; as is the cafe when their furfaces are of a moffy, loofe earthy, or a binding clayey quality, where harrowing or fcarifying, and the application of top-dreffings will be neceffary.

They are alfo farther diftinguifhed into natural and artificial, or common and watered meadows.

The former, from their being fituated in the hollows and floping fides of the vallies, where the depth of the foil has been conftantly increafing by the depofition of various forts of vegetable and other matters brought down from the higher grounds, are, it is fuppofed by a late writer, in a confiderably greater ftate of fertility, and evidently better fitted for the permanent production of grafs, than thofe from which they have derived their richnefs. And it has been well obferved, in the report of Staffordfhire, that this, of all others, is "the moft productive of grafs and hay, yielding fuftenance for cattle through the fummer and the winter, and producing an everlafting fource of manure for the improvement of the adjoining lands. Alfo, that in all cafes of extenfive inclofures, the improvement of the vale land, or that formed by nature for meadow and pafture, fhould be firft attended to. In this view, the low lands in all fituations come under the head of natural meadows."

And the latter are thofe which lie contiguous to rivers or brooks, whence the water can be eafily carried or conveyed fo as to overflow the grafs at pleafure. Of thefe there are large tracts in feveral parts of the kingdom, which, where fkilfully managed, become highly profitable to their owners, affording not only immenfe crops of hay, but yielding an abundant early grafs for the ufe of ewes and lambs, in the beginning of the fpring long before the pafture or other grounds are ready to receive them.

However, as the former fort of meadow lands, from their retention of moifture in confequence of their fituation, and the great depth of vegetable matter which they contain, are fuggefted by a late writer to be liable to throw up much more coarfe herbage, of the aquatic or other kind; in many cafes more drainage as well as other management will be neceffary to bring them into the proper condition for the growth of good herbage than is requifite in the hay grounds in more elevated places. And that, "by a more particular attention in thefe refpects they would, in many inftances, be rendered a vaft deal more productive than they are at prefent, and, at the fame time, afford a much better and lefs coarfe herbage. They would alfo admit ftock upon them a much greater length of time, both in the autumn and fpring feafon."

It may be noticed, that "the moft proper feafon for furface draining grafs lands is in the autumn, when they are firm and dry, as in the early fpring months fuch lands are too full of moifture. The grips, or fmall open drains, fhould ſhould be cut obliquely in the moſt ſuitable directions for conveying off the ſuperficial ſtagnant water. It is a practice, in ſome caſes, to ſuffer the ſods or grippings that are taken out of the trenches to remain on their ſides; but it is much better, and a leſs ſlovenly mode, to have them conveyed from the land and laid up in heaps, in order to their being acted upon by the winter froſts and other cauſes, ſo as to be brought into a ſtate proper for being formed into compoſts with well rotted farm-yard dung. Much of this ſort of draining may be performed at a ſmall expence, and the beneficial effects be very conſiderable, eſpecially where the lands are very much loaded with moiſture, in the quantity of produce." Beſides, ſuch meadow lands "demand much more attention in their management in other reſpects, as thoſe of their being fed by cattle, and the performing of the different operations that are proper for rendering them productive of good herbage. In theſe caſes, ſtock ſhould be turned upon the lands, and manures be applied with much care, and only when the land is in ſuch a ſtate of dryneſs as not to be injured by the poaching or breaking of the ſward. The higher ſorts of graſs lands, in moſt inſtances, admit of conſiderably more latitude in performing theſe different operations, as they are capable of admitting the ſtock as well as the dung-cart more early in the ſpring months, and of ſuffering them to remain or be applied at later periods in the autumn without inconvenience. The advantage of this attention is rendered ſufficiently plain by the effects which the contrary practice produces in ſuch meadow and other hay lands as are in a ſtate of commonage, where the ſtock is admitted at all ſeaſons, and under all circumſtances."

It is evident that "theſe ſorts of graſs lands muſt be applied to different purpoſes, according to their nature, ſituation, and other circumſtances. Thoſe which are of the more moiſt and wet kinds, whether from the nature of the ſoil, or the peculiarity of ſituation, and which have been a long time in the ſtate of ſward, are for the moſt part kept under the ſcythe; while thoſe of the contrary deſcriptions, that are ſituated at a greater height, and of courſe, in moſt caſes, poſſeſs a greater degree of firmneſs, are, in general, appropriated to the purpoſe of paſturage; though, in particular ſituations, where graſs land is ſcarce, and conſequently of great value, they are occaſionally likewiſe converted to the purpoſe of hay. And as graſs plants grow to the greateſt height in ſituations where a conſiderable degree of moiſture is conſtantly preſerved, and, of courſe, afford the largeſt produce, it would ſeem that the practice of keeping them under the ſcythe is right on this account; as well as that of their being leſs firm and ſolid in their texture, and their moſtly producing a coarſer herbage. The more elevated grounds, as they bear the ſtock generally with leſs injury, and often afford both a more fine and ſweet feed, are with propriety converted to the uſe of being fed down by animals. By a ſuitable management in the feeding and uſe of manure, the latter ſort of lands may even be brought to afford a conſiderable produce in hay in numerous inſtances.

And "as it muſt be evident to the moſt ſuperficial obſervation, that the breaking of the ſurface texture or ſward of graſs lands muſt, in all caſes, be prejudicial, not only by the deſtruction of plants which is thereby immediately produced, but alſo by the retention and ſtagnation of water upon them in the holes, and depreſſions from ſmall portions of the turf being forced in, the neceſſity and utility of clearing and removing all ſorts of live ſtock, and eſpecially thoſe of the heavy kinds, on both theſe deſcriptions of meadow land when mown, becomes ſtrikingly obvious."

There is a ſtriking fact of this ſort ſtated in the Agricultural Report of Middleſex. "In a piece of clayey meadow land expoſed to the treading of cattle during the wet ſeaſon of winter, with a view of fully aſcertaining the effects of the practice of ſuffering cattle to remain too long upon graſs hay lands, it was found that after three years, notwithſtanding every poſſible care and attention in rolling, manuring, and ſowing graſs ſeeds was employed, it was not reſtored to its former ſtate of ſward." And it has been remarked, that on the deep tough yellow clayey graſs lands in the ſame diſtrict, every care is taken to prevent the leaſt degree of poaching, as "it is well known that wherever a bullock makes a hole with his foot in this kind of ſoil, it holds water, and totally deſtroys every veſtige of herbage, which is not quite replaced till ſeveral years after the hole is grown up."

In regard to the exact period of continuing the feeding down of graſs lands of the hay kind, it cannot be eaſily regulated by any fixed rules, as it muſt depend much on ſeaſons; but it ſhould never, on any account, be continued after the grounds have become ſo much impregnated with moiſture as to eaſily give way to the tread of animals. In the autumn ſeaſon the heavy cattle ſhould ſeldom be ſuffered to remain on the ſofter ſorts of lands longer than the beginning of November, but in thoſe of the more dry kinds, they may be let remain to the end of that month. Sheep ſtock may, in drier caſes, be continued till February, or later; and in the ſpring ſeaſon, if paſtured at all, they ſhould not be admitted upon ſuch lands till they begin to poſſeſs a proper degree of firmneſs, which will depend on the various circumſtances of the preceding ſeaſon. On the more low and moiſt ſorts of meadow land, it can probably ſeldom be ventured earlier than the middle of March.

It is, however, obviouſly a much better practice, eſpecially where hay is the main object, not to eat them down at all, or very little, with cattle in the ſpring, and not ſo much as is the uſual cuſtom with ſheep; as it is plain, that by this means the cultivation will not only enſure a more abundant produce, but a much earlier one, and, of courſe, have more advantage in the making it into hay and ſecuring it.

Beſides, where the lands are fertile and the graſs ſprings quickly, as is often the caſe near large towns where manure is plentiful, it may be advantageous in the view of having a ſecond crop, as by that means the after-graſs may be cut more early, and be leſs in danger of being well ſecured; and, in all events, the after-graſs will be in a more forward ſtate, and, of courſe, ready at a more early period for the admiſſion of ſtock of different kinds, which, in many caſes, is a circumſtance of great importance to the farmer where grazing is the main object.

With reſpect to the moſt proper periods of ſhutting up ſuch graſs lands as are deſigned for hay, they muſt, like thoſe of eating them down by ſtock, depend on various circumſtances that can only ſuit the particular caſes. In general, however, it is the beſt practice not to delay it too long. When the lands are not eaten at all in the ſpring by cattle, after the ſheep have been removed about the middle of February; nothing farther is allowed, according to the writer of the Middleſex Report, to enter the meadows, by which means a quick vegetation is promoted, as well as a more plentiful crop and more early harveſt. And in other caſes it ſhould probably ſeldom much exceed the beginning of April, as when eaten much later, eſpecially in the ſouthern diſtricts, there is not time for the graſs to produce a full crop before the commencement of the hay ſeaſon, of courſe the farmer ſuſtains more loſs than can be repaid by any advantage in the additional feeding he may obtain. This

is

is therefore the beſt practice where the view of the farmer is hay: and it ſhould be particularly adopted and attended to in cow-farms, where it is of much importance to cut early and at different times, in order to ſecure hay of a fine graſſy quality, for the purpoſe of producing large ſupplies of milk. In theſe caſes it is cut two, three, or more weeks before the uſual period, as it is better not to let the ſeed ſtems riſe much.

Immediately after the meadows or other graſs-lands have had the cattle and other ſorts of live ſtock removed from them, in the early ſpring months, and been ſhut up for hay, they ſhould be prepared for the ſcythe, by having all ſorts of obſtructions picked up and removed from the ſurface. This work ſhould always be executed as ſoon as poſſible, before the graſs begins to ſpring up too much and conceal them, as it is difficult to perform the buſineſs effectually afterwards. And it has been obſerved, that "it is an excellent practice, but one that is too much neglected by graſs-farmers in general, to have all ſorts of coarſe plants of the aquatic and other kinds, ſuch as ruſhes, fern, docks, thiſtles, and various others, effectually drawn up and eradicated both from the hedge-rows and other parts of the fields, in order to prevent their running up to ſeed and diſſeminating themſelves over the lands, and thus not only fill them progreſſively with all ſorts of trumpery, but greatly injure the herbage. In a field on an extenſive hay-farm in Middleſex, on perceiving the whole ſurface thickly ſtudded with thiſtle-plants, it was found that this ſort of weed had been ſuffered to flower and perfect its ſeed annually, until the lands on every ſide had become fully ſtocked, to the vaſt injury of the hay-crops. The ſame thing takes place with the dock, and ſeveral other noxious plants, which ſtrongly enforces the utility of the practice juſt recommended. The annual expence of performing the buſineſs is but a mere trifle, while the advantage will be real and permanent. The ſaving to the farmer would be conſiderable, by having the work regularly done as ſoon as the weeds ſhew themſelves, and at the ſame time his young hedge-plants be prevented from being deſtroyed, by being ſhaded and choaked up by ſo many weeds. In order to take them up in a perfect manner, a narrow implement of the ſpade kind, ſuch as is made uſe of in forming narrow drains, may be employed with advantage, as cutting or breaking them off is by no means effectual. After ſuch plants have been removed, and the ground well cleared, ſowing the banks and hedge-rows with the beſt graſs-ſeeds, ſuch as white clover and other ſimilar plants, might be an excellent practice, as in this way the lands may be improved rather than injured."

In regard to plants of the ruſh kind, they may be eaſily removed by preventing the ſtagnation of moiſture near the ſurface, by judicious under or ſurface draining, and the application of ſubſtances of the ſaline or calcareous kinds, ſuch as aſhes, lime, drift from the roads, and other ſimilar materials. Theſe are the beſt made uſe of in a dry ſeaſon, in either the autumn or ſpring; but the latter is probably the beſt, as theſe abſorbent matters will thereby be made uſe of at the time ſuch plants begin to ſhoot and eſtabliſh themſelves, and when there will be the leaſt danger of their operation being leſſened or prevented by too great a degree of moiſture. It has been obſerved, that in natural coarſe meadows, or ſuch as become ſo in conſequence of ruſhes growing upon them, before they have been rendered ſufficiently dry by draining, it forms a great improvement to apply a thin coat of ſand evenly over the ſurface of them, in the proportion of from twenty to thirty common loads. By this means the ſward is rendered much finer, and a much better ſort of herbage brought up; white clover being predominant in moſt caſes where this is practiſed.

But there is another method that, in particular ſituations, may be more eaſy and convenient, and which has been found to quickly deſtroy plants of this coarſe kind, by bringing up thoſe of a finer deſcription. This may appear extraordinary at firſt ſight to thoſe who have not ſeen its ſudden and aſtoniſhing effects in this way. It is that of conducting water over the ſurface of ſuch grounds; but, in this intention, it ſhould not be ſuffered to have the leaſt degree of ſtagnation, but be conveyed off with as much expedition as poſſible, by ſuitable drainage or other means.

M. de Chateauvieux many years ago invented a machine, called a cutting-plough, with three ſharp coulters for cutting the land about ſix or ſeven inches deep, that the manure laid upon it might be waſhed into the inciſions made by the coulters, and which alſo, by cutting the old roots of the graſs, many new roots were produced, and a very great improvement afforded, particularly where the meadows were hide-bound and overrun with moſs. And afterwards Mr. Wynn Baker, in Ireland, added two more coulters, and named it a *ſcarificator;* which is conſidered a very uſeful tool for the purpoſe of improving meadows, as well as paſtures. For it has been found in practice, that if the land is firſt ſcarified, and then manured, the improvement is greater than ſcarifying the land after laying on the manure. And this buſineſs is ſaid alſo to be well performed by a ſward-dreſſer, invented by Mr. Amos in Lincolnſhire. See SWARD-*Dreſſer*.

In caſes where meadow-lands are properly ſituated for the purpoſe of being watered, they may be formed properly for the purpoſe, probably with the moſt advantage, in the early autumn; but when that ſeaſon cannot be conveniently employed, the work may be performed early in the ſpring. The methods of cutting the gutters and trenches, and of managing the whole of the proceſs, as well as the vaſt utility which is the reſult of it, may be ſeen detailed under the heads IRRIGATION and WATERING *of Land*.

Where this practice is attempted, the farmer ſhould commence the watering of his meadow-lands early in November, which, in moſt inſtances, affords more improvement than a dreſſing of the beſt manure that can be provided. As they are commonly the lower parts of the ground that can be made uſe of in this way, much may often be effected by a proper attention to the ditches in the lands that lie at higher levels, as by keeping them in ſuch a ſtate that they may diſcharge themſelves freely into a large main ditch, a little above the lower parts of them, from which the water may be let off occaſionally, ſo as to float the meadow grounds below; care being taken that it does not ſtagnate upon them in any way. And in managing this ſort of operation afterwards, Mr. Wright adviſes that the floater ſhould take care to keep the land ſheltered by the water from the ſeverity of froſty nights. And in the winter, as about January, it is neceſſary, he conceives, every ten days or fortnight to give the land air, and to lay it as dry as poſſible, for the ſpace of a few days. "Whenever the froſt has given a complete ſheet of ice to the meadow, it is adviſable to diſcontinue floating; for the froſt will ſometimes take ſuch ſtrong hold of the land, as to draw it into heaps, and injure the evenneſs of the ſurface. Attention is alſo to be paid to prevent the equal diſtribution of the water being obſtructed, by the continual influx of weeds, leaves, ſticks, &c." And, as the ſeaſon advances, ſtill greater attention is required from the floater in the ſucceeding month: "if the water be ſuffered to flow over the meadow, for the ſpace of many days without intermiſſion, a white ſcum, it is obſerved, is generated, which is found

very

very deſtructive to graſs; and if the water be taken off, and the land expoſed in its wet ſtate to a ſevere froſty night, a great part of the tender graſs will be cut off. In Glouceſterſhire, two methods of avoiding theſe injuries are practiſed: one is, to take the water off by day, to prevent the ſcum, and to turn it on again at night, to guard againſt the froſt; the other method is to take the water off early in the morning, and if that day be dry, to ſuffer it to remain off for a few days and nights; for if the land experiences only one drying day, the froſt at night will do little injury. The former of theſe practices, where it is found not too troubleſome, is preferable to the latter." About the middle of February, the floater ſhould begin to uſe the water more ſparingly than in autumn or winter; for his chief object now is to encourage or force vegetation. It is moſtly found, that about the laſt week of this month, if the preceding management has been good, there will be a pretty full bite for ewes and lambs. Some adviſe rolling in the beginning of the year, as about January.

The ſame writer alſo ſtates, that "about the beginning of March, the graſs on the old floated meadows will generally be ſufficient to afford an abundant paſturage to any kind of farming ſtock; and the water muſt be taken off for nearly a week, that the land may become dry and firm before heavy cattle are admitted. It is proper, in the firſt week of eating off the ſpring feed, if the ſeaſon be cold and rainy, to give the cattle a little hay in the evening to intermix with their moiſt food. But the grand application of the young meadow-graſs is for ewes and lambs; and attention ſhould always be paid to hurdling off the graſs, and giving ſtripes acroſs the meadow, exactly in the way turnips are hurdled for ſheep. The caution of Mr. Boſwell, never to feed on theſe meadows any heavier ſtock in ſpring than ſheep or calves, ſeems to be judicious, but muſt obviouſly depend much on ſoil; for, upon a ſound gravel, a practice may be admitted, which would be miſchievous on a peat meadow." But good rich meadows, whether watered or not, are moſtly ready to be cut about the middle of June.

Mr. Boſwell adviſes, that "as ſoon as the hay is cleared from theſe meadows, cattle of any ſort (no ſheep) ſhould be turned in for a week to eat the graſs out of the trenches, and what may be left by the mowers. Then the water ſhould be worked on them, care being taken to let it only dribble over every part as thinly as poſſible; this being the warmeſt ſeaſon of the year. The firſt watering ſhould not laſt longer than two or three days, before it is ſhifted to another meadow. There will ſoon be an after-graſs of ſuch a rich and beautiful verdure as will aſtoniſh a ſpectator not accuſtomed to it; and the quantity and quality will be beyond conception, compared with the ſtate the lands were in before they were watered. He alſo further cautions us to guard by all means againſt keeping the water too long upon the meadows, in warm weather. It will very ſoon produce a white ſubſtance like cream, which is prejudicial to the graſs, and ſhews it has been upon the ground too long already; but if permitted to remain a little longer, a thick ſcum will ſettle upon the graſs, of the conſiſtence of glue, and as tough as leather, which will quite deſtroy it."

Meadow-*Graſs*, in *Botany*. See Poa, Cynosurus, and Grass.

Meadow-*Fox-tail Graſs*, in *Agriculture*, a ſort of field graſs, that may be cultivated to advantage on the more moiſt ſorts of ſoil. It is ſaid to be early and productive, but rather coarſe. See Alopecurus *Pratenſis* and Grass.

Meadow *Rue*. See Thalictrum.

Meadow *Saffron*. See Colchicum.

Meadow *Saxifrage*. See Peucedanum and Seseli.

MEADVILLE, a thriving poſt-town, ſeated on French creek, a branch of the Alleghany, in Crawford county, Pennſylvania (N. lat. 41° 36'), and the ſeat of juſtice for the counties of Warren and Crawford, to the latter of which it belongs. It contains about 100 houſes, and ſeveral ſtores, and is a place of conſiderable buſineſs.

MEAGOM, a town of Hindooſtan, in Guzerat; 20 miles N. of Baroach.

MEAHGURRY, a town of Hindooſtan, in Candeiſh; 30 miles S.E. of Chuprah.

MEAHMAO, a large town of the Birman empire, on the Irawaddy, ſhaded by groves of palmyra trees, and remarkable for a manufacture of coarſe cloth, ſuch as is worn by the lower claſs of people; 42 miles W. of Ava.

MEAKING, a town of the Birman empire, on the right bank of the Ava; 8 miles N. of Penongmew.

MEAL. The meal or flour of England is the fineſt and whiteſt in the world. The French is uſually browner, and the German browner than that. Our flour keeps well with us; but in carrying abroad, it often contracts damp, and becomes bad. All flour is ſubject to breed worms: theſe are white in the white flour, and brown in that which is brown; they are therefore not always diſtinguiſhable to the eye: but when the flour feels damp, and ſmells rank and muſty, it may be conjectured that they are there in abundance.

The colour and the weight are the two things which denote the value of meal or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions theſe two characters as the marks of good flour, and tells us, that Italy, in his time, produced the fineſt in the world. This country, indeed, was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles, in particular, ſays, that no flour is ſo white or ſo good as that of Italy. The corn of this country has, however, loſt much of its reputation ſince that time; and the reaſon of this ſeems to be, that the whole country being full of ſulphur, alum, vitriol, marcaſites, and bitumens, the air may have, in time, affected them ſo far, as to make them diffuſe themſelves through the earth, and render it leſs fit for vegetation; and the taking fire of ſome of theſe inflammable minerals, as has ſometimes happened, is alone ſufficient to alter the nature of all the land about the places where they are. Deſland. Trait. Phyſ.

The flour of England, though it pleaſes by its whiteneſs, yet it wants ſome of the other qualities valuable in flour: the bread that is made of it is brittle, and does not hold together, but, after keeping a few days, becomes hard and dry, as if made of chalk, and is full of cracks in all parts; and this muſt be a great diſadvantage in it, when intended for the ſervice of an army, or the like occaſions, where there is no baking every day, but the bread of one baking muſt neceſſarily be kept a long time.

The flour of Picardy is very like that of England, and, after it has been kept ſome time, is found improper for making into paſte or dough. The French are forced either to uſe it immediately on the grinding, or elſe to mix it with an equal quantity of the flour of Brittany, which is coarſer, but more unctuous and fatty; but neither of theſe kinds of flour keeps well.

The flour of almoſt any country will do for the home conſumption of the place, as it may be always freſh ground; but

but the great care to be used in selecting it is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea-air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find, that the flour of Poitou, Normandy, and Guienne, all bear the sea-carriage extremely well, and they have formerly made a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships: the keeping it dry is the grand consideration in regard to this; the barrels in which it is put up ought to be made of dry and well-seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will moisten and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since, when once well dried and seasoned, it will not contract humidity afterwards. The beech-wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable, because of its being free from these faults; and when the several kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so, than this for the purpose. The great test is their having more or less sap. See FLOUR and WOOD.

MEAL *Worm*. See WORM.

MEALY-*Tree*, in *Botany* and *Gardening*. See VIBURNUM.

MEAMBOLANGAM, in *Geography*, a town of the Birman empire, on the Ava; 36 miles N. of Prome.

MEAMOY, a town of the Birman empire, on the right bank of the Ava; 16 miles W. of Ava.

MEAN, the middle, between two extremes.

Thus we say, the mean motion of a planet; its mean distance, &c. meaning a motion or distance, which as far exceeds the least distance or motion, as it is exceeded by the greatest.

MEAN, middle, mean proportion, is the second of any three proportions; but in music, mean is more properly the title of the second violin in trios, as being the mean between the first violin and base. In madrigals of five and six parts, a third treble is generally termed the mean part.

MEAN, in *Law*, refers either to time or dignity. Thus, in the first sense we say, his action was mean betwixt the disseisin made to him, and his recovery; *i.e.* in the interim.

In the second sense, we say, there is lord *mean* or *mesne*.

MEAN, in *Logic*. See MEDIUM.

MEAN *Anomaly*, in *Astronomy*. See ANOMALY.

MEAN *Axis*, in *Optics*. See AXIS.

MEAN $\left\{\begin{array}{l}\textit{Conjunction,}\\ \textit{Opposition,}\end{array}\right\}$ in *Astronomy*, is when the mean place of the sun is in $\left\{\begin{array}{l}\text{conjunction}\\ \text{opposition}\end{array}\right\}$ with the mean place of the moon in the ecliptic. See CONJUNCTION and OPPOSITION.

MEAN *Diameter*, in *Gauging*. See GAUGING.

MEAN *Distance of a Planet from the Sun*, in *Astronomy*, is the right line drawn from the sun, to the extremity of the conjugate axis of the ellipsis in which the planet moves; and this is equal to the semitransverse axis, and is so called because it is a mean between the planet's greatest and least distance from the sun.

MEAN *Motion*, that whereby a planet is supposed to move equally in its orbit, and is always proportional to the time.

MEAN *Proportion*. See EXTREME *Proportion*.

MEAN *Time*. See TIME.

MEANA, in *Geography*, a town of Hindoostan, in Kitchwara; 10 miles N.E. of Budawar.—Also, a town of the island of Sardinia; 21 miles S.S.W. of Lode

MEANG, a town of Hindoostan, in Guzerat; 40 miles N.W. of Puttan-Sumnaut.

MEANGIS, a cluster of small islands in the North Pacific ocean. N. lat. 4° 58′. E long. 126° 55′.

MEANY, a town of Hindoostan, in Guzerat, near the coast; 40 miles S.W. of Junagur.

MEANY, *Choppa*, a town of Hindoostan, in Guzerat, on the coast; 55 miles W. of Junagur.

MEAO, one of the small Molucca islands. N. lat. 1° 12′. E. long. 127° 3′.

MEARIM, a river of Brazil, which runs into the bay of Baranhao, S. lat. 2° 40′. W. long. 45° 30′.

MEASLES, in *Medicine*, a contagious fever, accompanied by a rash or efflorescence on the skin, of a peculiar form or distribution, which mostly appears on the fourth day of the fever, and, after a continuance of four days, gradually declines together with the febrile symptoms.

This disease, like the small-pox and scarlet-fever, was not particularly described or named by the Greek and Roman physicians, but is first mentioned by the Arabians. The translators of the writings of the latter into Latin applied the term *morbilli* to the disease; as it were a *little plague*, the word *il morbo*, in Italy, signifying the plague, or *the disease*, by way of eminence. Subsequently, from the red colour of the rash, the terms *rubiolæ* and *rubeolæ* were given to this disease, and to scarlet-fever, which was confounded with it. The appellation of *rubeola* has been adopted for the measles by our best nosologists, Sauvages and Cullen. The English term *measles* seems to have been borrowed from an appearance, which was so denominated in the flesh of pork, to which the eruption of rubeola was supposed to bear some resemblance.

The disease in question is propagated solely by contagion; and it commences in children, or in adult persons of an irritable constitution, from ten to fourteen days after they have been exposed to the infection. Others, who are less susceptible, may have frequent communication with persons affected with the disease during several successive weeks, but the contagion does not act upon them, unless the body be brought into a feverish state by some incidental cause, as by taking cold, by watching, fatigue, or mental distress. Dr. Willan, in his valuable and elaborate treatise on cutaneous diseases, has described three varieties of measles, which it is important to attend to: these are the rubeola *vulgaris*, or common form of the disease; the rubeola *sine catarrho*, in which fever and catarrh do not accompany the eruption; and the rubeola *nigra*, or purple-measles.

1. The *rubeola vulgaris*, or usual form of measles, exhibits the following character. The symptoms which precede the efflorescence are, on the first and second days, irregular shiverings alternating with heat of the skin, general debility or listlessness, flushing of the cheeks, giddiness, a sensation of pain or weight across the forehead and eyes, with drowsiness; sometimes pain of the back and limbs, slight

ſlight ſoreneſs or roughneſs in the throat, loſs of appetite, frequent nauſea, thirſt, a white fur on the tongue, clear high-coloured urine, the pulſe much increaſed in frequency, and ſomewhat labouring or irregular. On the third and fourth days, the ſame ſymptoms continue, but with greater violence: the eyes become tender and inflamed; the eye-lids and tarſi appear a little turgid; at the ſame time a ſerous humour is copiouſly diſcharged both from the eyes and noſtrils, which occaſions repeated ſneezing. The diſeaſe during this period, and uſually for two or three days longer, is accompanied with a frequent dry cough, hoarſeneſs, difficulty of breathing, and a ſenſe of conſtriction acroſs the cheſt. In children, indeed, in whom all the ſymptoms of the firſt ſtage are more ſevere than in adults, the diſeaſe is often preceded by a harſh ſounding cough for a week, or even a fortnight, before it formally commences; and ſometimes, eſpecially during the period of dentition, is attended with frequent twitchings, or even with ſtrong convulſive fits.

We have ſaid that the efflorescence moſtly appears on the fourth day of the fever: this, however, is not invariably true. In perſons who have a very delicate ſkin, it ſometimes appears partially on the third day; while in others, of a dark and thick ſkin, or who have been expoſed much to cold, it may not be manifeſt till the fifth or ſixth day: and as the contagion is, in many perſons, only called into action by ſome incidental feveriſhneſs; ſo it is not eaſy, in theſe caſes, to aſcertain the commencement of the proper eruptive fever.

The raſh is firſt viſible on the face, eſpecially on the forehead and under the chin, and exhibits in other parts only a few ſcattered ſpecks, with a ſomewhat warmer colour of the ſkin than uſual. On the following (fifth) day, it is formed on the neck and breaſt in the morning, and is diffuſed, towards evening or in the night, round the trunk of the body, and along the extremities; during this day it is moſt full and vivid on the face. On the *ſixth* day of the diſeaſe, the raſh on the face begins to fade and ſubſide, while the patches on the body are moſt red and extended; but theſe gradually change their appearance the day after. The patches on the back of the hand and wriſt, which uſually appear lateſt (in ſome inſtances on the ſixth or ſeventh day), do not always decline till the *eighth* day. On the *ninth* day, there remain only veſtiges of the efflorescence, marked by a ſlight diſcolouration; this, however, diſappears before the end of the *tenth* day. When the raſh begins to decline on any part, the cuticle becomes dry and rough, and ſoon after ſeparates into ſcurf. Hence ariſes a very diſagreeable itching of the ſkin which continues from the ſeventh to the tenth day.

The progreſs of the eruption is ſometimes checked by expoſure to continued cold; and its retroceſſion occaſions delirium, reſtleſſneſs, difficulty of breathing, pain of the bowels, diarrhœa, &c. and endangers the life of the patient. The inflammation of the eyes, the diſcharge of tears, the ſneezing, and hoarſeneſs, generally ceaſe on the decline of the efflorescence, about the ſeventh day; at leaſt they are always much abated at that time, and the appetite for food returns. Between the fourth and ſixth days there is often a hæmorrhage from the noſe, and in females an appearance of the catamenia out of their courſe; but theſe circumſtances occur in other eruptive diſeaſes.

It is neceſſary, however, to attend to the form and mode of diſtribution of the efflorescence, as well as to its progreſs and periods, with a view to avoid miſtakes as to the nature of the diſeaſe; which has been frequently, and indeed for many centuries was conſtantly confounded with ſcarlet-fever, and other febrile raſhes. The colour of the raſh in the meaſles, Dr. Willan obſerves, is leſs bright than in ſome other diſeaſes of the exanthematous claſs. It verges towards the raſpberry tint, rather than the ſcarlet or roſe hue of ſome other raſhes. On the eighth day, when the efflorescence declines, it changes to ſomewhat of a yellowiſh hue. The raſh commences with diſtinct, red, and nearly circular dots, about the ſize of common flea-bites, to which moſt writers have compared them. Larger patches afterwards appear, or rather theſe dots, becoming more numerous, coaleſce into larger patches, which, although not exactly defined, approach neareſt in their form to the figure of a creſcent, or ſemicircle. Theſe patches are ſlightly raiſed, and give to the finger the ſenſation of an unequal ſurface. Many of the patches are interſperſed with the ſame ſmall circular dots; but there are, for the moſt part, large interſtices of cuticle retaining its uſual colour.

From theſe characteriſtic appearances of meaſles there are only partial variations: as, 1ſt. The fluſhed and tumefied ſtate of the cheeks, while the fever continues, may obliterate or obſcure the form of the raſh on thoſe parts. 2dly. In infants leſs than a year old the efflorescence is much ſcattered; and on the cheeks, noſe, backs of the hands, &c. it often conſiſts of diſtinct pimples (*papulæ*). The wriſts, hands, and fingers are alſo frequently papulated in adults. 3dly. In many perſons, at different ages, there are, during the height of the efflorescence, lymphatic or miliary veſicles on the neck, breaſt, and arms. Willan on Cutan. Diſeaſes, p. 217, & ſeq.

Dr. Heberden has noticed the following particularities of the meaſles: "One patient was ſeized with a ſpitting on the fourth day, which continued to teaſe him for forty-eight hours, without ſuffering him to reſt at all by day, or to ſleep at night: the cough in the mean time almoſt ceaſed, and all the other ſymptoms were as mild as in a favourable ſort of the meaſles.

"In one or two patients I have ſeen the eruption appear on the arms a few hours after its having been obſerved on the face and neck.

"Once or twice the diſtemper has been obſerved never to have reached the arms, which parts, through the whole of it, ſhewed none of the uſual ſpots.

"The eye-lids have been ſo ſwelled, on the ſecond day of the eruption, that for twenty-four hours they could not be opened.

"In ſeveral patients the marks on the face have been on the third and even fourth day of the eruption, of as bright a red as ever. In others, I have obſerved them to diſappear entirely on this day, and all other ſymptoms likewiſe to retreat.

"I have noted a very troubleſome and conſtant ſneezing, which firſt came on upon this day.

"A child, five years old, became comatoſe the third day of the eruption, and died the next.

"The longer the preparatory ſymptoms have continued and the worſe they were, ſo much the leſs mild the diſtemper proved.

"Thoſe who have ſhewn the leaſt remains of the eruption after the ſeventh day of the diſeaſe (and ſome have hardly ſhewn any) have appeared the beſt; and in thoſe where it was ſtill in undiminiſhed vigour, the cough and fever have been the worſt." See a Paper in the Med. Tranſ. of the Coll. of Phyſ. vol. iii. Alſo, Dr. Heberden's Comment. de Morb. cap. 63.

The eruptive ſtage of the meaſles is not attended with much danger, either to infants or adults. The fever, indeed, does not receive any immediate alleviation, but is often ſomewhat aggravated on the appearance of the raſh: yet the nauſea and

and vomiting feldom continue beyond the fourth day of the fever, as Sydenham has juftly remarked; and the diftreffing heat, panting, and reftleffnefs abate on the fixth day. The fubfequent period of the difeafe, however, may prove fatal to patients of any age. Between the ninth and twelfth day, fome children are unexpectedly attacked with great difficulty of breathing, or fuffocation, and die in a few hours. In others, the diarrhœa, which ufually fupervenes on the difappearance of the rafh, about the ninth or tenth day, continues, without intermiffion, for fo long a period that it exhaufts their ftrength, and they become pale and emaciated; under thefe circumftances aphthous ulcerations of the mouth are generally the fore-runners of death. Adults, as well as children, fall fometimes into a ftate of hectic fever, which returns twice in twenty-four hours, without any cough or diarrhœa; and during the intervals there is great reftleffnefs and a quick irregular pulfe. The patients thus affected, for two or three fucceffive weeks, gradually fink under the complaint; but in fome inftances a fatal termination feems to be averted by the appearance of boils, puftules, or fuppurating tubercles on the fkin, which operate very favourably with refpect to the internal diforder, both in this hectic ftate, and in cafes where the bowels or the lungs are feverely affected. Sometimes this alleviation is fpeedily produced by an eruption of inflamed watery veficles round the cheft, or more flowly by a difcharge from behind the ear, or from the ear itfelf, accompanied with fuppuration in fome of the lymphatic glands. When nothing of this kind appears externally, the inflammation of the lungs in adults is fometimes on a fudden greatly aggravated; the cough ceafes, refpiration becomes more and more laborious, with a fenfe of oppreffion and anxiety: the eyes are glaffy, the countenance livid, the extremities cold, and the pulfe fcarcely difcernible. After a ftruggle of three or four days, the difeafe has a fatal termination, the caufe of which diffections have afcertained, in feveral cafes, to be an effufion of lymph, mixed with blood or matter, into the cavity of the thorax. Willan.

Even when the meafles pafs through their courfe moderately and mildly, however, various diforders follow them, or a tendency to fome other difeafe is not unfrequently left behind; fo that the confequences of this fever are often more to be dreaded than the original difeafe itfelf. In many perfons the cough, foon after the difappearance of the rafh, recommences with violence, being attended with difficulty of breathing, fixed pain in the fides, flufhing of the cheeks, quick pulfe, and often with paroxyfms, as in a hectic. This ftate is protracted much longer than pneumonic inflammation produced by cold, and more frequently terminates by effufion into the cavity of the cheft, or by fpitting of blood, fuppuration, and confirmed pulmonary confumption. There are alfo fome other appearances which occafionally fucceed the meafles, efpecially difeafes of the fkin and glandular fyftem, which mark a cachectic ftate of the habit. Among thefe are fmall hard tumours, like boils, occurring on the back, loins, and lower extremities, which are very much inflamed in the beginning, and afterwards fuppurate with great pain, and a fanious difcharge; herpetic eruptions, in patches of watery veficles, with an inflamed bafe, about the cheft, mouth, &c. producing much heat, pain, and tingling of the fkin; foft puftules, containing a vifcid ftraw-coloured fluid on the head, face, breaft, and thighs, fucceeded by ulcerations at the corner of the mouth, with tumour of the upper lip, inflammation of the eyes, and ulcerations at the edges of the eye-lids, difcharges behind the ears, enlargement and tedious fuppuration of the lymphatic glands under the jaw, in the neck, arm-pits, and groin, fometimes with pain and fwelling of the joints, and every other form of fcrofulous difeafe.

Treatment of Common Meafles.—The rubeola vulgaris is ufually a mild difeafe in the fummer months, being attended with a moderate degree of fever, and but little cough; in January, February, and March, it is moft frequent, and likewife moft fevere and dangerous.

In the eruptive ftage of the difeafe, it is neceffary to enjoin a very light diet, with mild tepid drinks; and to keep the patient in a moderate temperature, carefully guarding againft any great or fudden changes. An emetic given on the fecond or third evening affords fome flight alleviation to the violence of the catarrhal fymptoms. During the eruption, however, no confiderable effect appears to be produced by antimonials, or other diaphoretics; and emulfions and mucilages afford but a very feeble palliation of the cough and difficulty of breathing. The firft of thefe objects, to wit, of foftening the fkin, feems to be more efficiently accomplifhed by the ufe of the warm pediluvium every evening; and the latter by the infpiration of the fteam of hot water. If a diarrhœa comes on during the continuance of the efflorefcence, it is generally favourable, relieving the cough, and allaying the inflammatory fymptoms: where this does not fupervene, therefore, it is advifable to adminifter occafional purgatives, which will be found to produce a fimilar relief, and often fuperfede the neceffity of more violent remedies.

Almoft all authors, down to our own time, have afferted the neceffity of blood-letting in this difeafe, differing only in regard to the period when it may be practifed with moft advantage. Morton deemed it requifite during the height of the eruption, when he thought the difeafe was moft inflammatory; and Sydenham recommended it after the difappearance of the eruption, when fymptoms of pulmonary inflammation enfue. Whilft Mead and Heberden confidered the period of the difeafe as of little moment in determining the propriety of the practice, which the degree of inflammatory affection in the cheft, they contended, ought alone to decide. Dr. Heberden, however, recommended the ufe of the lancet as a general remedy in the meafles. "Bleeding may be ufed at any time of the meafles," he fays, "and is always beneficial where the fymptoms are very diftreffing, particularly an oppreffion of the breath, to which every ftage of this diftemper is liable; and *bleeding*, together with fuch medicines as occafional fymptoms would require in any other fever, is the whole of the medical care requifite in the meafles." Med. Tranf. vol. iii. p. 404.

In cafe the breathing becomes fuddenly difficult, threatening to fuffocate the patient, at the conclufion of the difeafe, as Sydenham ftates, there cannot be a doubt that blood-letting, even in children, may be reforted to with great benefit, and ought not to be omitted: in infants the application of leeches to the cheft may be fufficient. With refpect to the treatment of the oppreffion, however, conjoined with anxiety, heaving of the cheft, and a labouring pulfe, which take place on the third, fourth, or fifth day of the difeafe, Dr. Willan juftly obferves, that this remedy may be difpenfed with, unlefs there are at the fame time pains in the cheft, and a hard dry cough. "Thofe who from doubt, or from fome collateral motive," he ftates, "are led to await the event, ufually find the pulfe become moderate, and the uneafy laborious refpiration terminate in twenty-four hours. This oppreffed breathing is, indeed," he adds, "common to other eruptive fevers, and if it were univerfally confidered to be an indication for bleeding, the practice would often be more fatal than the difeafe." Loc. cit. p. 232.

 He

He goes on to remark, that "when the efflorefcence in meafles has wholly difappeared, and the cough, difficulty of breathing, and pains in the cheft are very fevere, bleeding and cupping may perhaps be repeatedly neceffary. Yet, even in robuft habits, fome limitation is requifite to this mode of practice; fince it has not an effect in alleviating the fymptoms, equal to that which is experienced from it in pulmonic inflammations originating from cold. Hence we fhould employ as auxiliaries to bleeding, at the latter period of the difeafe, blifters, opium, and demulcent liquors. Sydenham prefcribed an opiate every night through the whole courfe of the meafles; but this plan feems not beneficial in the eruptive ftage; I have obferved, and myfelf felt, while labouring under the difeafe, that opium did not conciliate fleep, but produced an increafe of heat and reftleffnefs, and therefore feldom direct it till the efflorefcence has declined. A diarrhœa occurring at this period may be accounted a moft favourable circumftance, fince nothing fo effectually relieves the peripneumonic fymptoms, or contributes more to prevent the troublefome confequences of the difeafe formerly mentioned. The neceffity of bleeding, as a remedy for the diarrhœa, is infifted upon by Dr. Sydenham from theoretical reafoning. Experienced practitioners in London feem to have now decided, that we ought not much to interfere with this critical evacuation, but rather allow it a free courfe, at leaft for fome days. Where the diarrhœa does not thus take place, it is proper to imitate the ufual procefs of nature, by the occafional ufe of purgatives, which will always be found to relieve the cough, and by allaying the inflammatory fymptoms, often to fuperfede the neceffity of blood-letting."

2. The *Rubeola fine catarrho*, which is fo mild as to require no medicine, is particularly entitled to notice, in confequence of a circumftance pointed out by Dr. Willan, and not obferved by other writers who had mentioned its occurrence; namely, that when the eruption of meafles occurs without the accompanying fever and catarrhal fymptoms, it does not appear to fecure the conftitution from the future influence of the contagion, nor to prevent the acceffion of the ordinary form of the difeafe at a fubfequent period. In this way he fuppofes that the inftances of the recurrence of meafles in the fame individual, which have been recorded, are probably to be explained, unlefs where other difeafes, fcarlatina, rofeola, ftrophulus, &c., have been miftaken for meafles; for he never faw the *febrile* meafles occur more than once in the fame perfon. In fome cafes the non-febrile eruption has occurred at the interval of two years before the rubeola vulgaris; in other inftances, a very fhort time has intervened. "I have feen other inftances of the fame kind," Dr. Willan fays, "wherein the efflorefcence without fever or catarrhal fymptoms having declined, there appeared on the fourth day from its commencement a new efflorefcence, and violent diforder of the conftitution. Thefe inftances are perfectly analogous to fome cafes of fmall-pox, in which diftinct puftules arife without any material complaint, and when thefe decline, about the eighth or ninth day after their appearance, the variolous fever takes place, with an eruption of confluent pocks over the whole furface of the body." P. 236.

The appearance of the efflorefcence of meafles, when the ordinary febrile and catarrhal fymptoms are abfent, is to be diftinguifhed from other rafhes, as well as from lichen and ftrophulus, which are *papular*, by a careful examination of its form and diftribution, as above defcribed. In infants, Dr. Willan obferves, the eruption of meafles "is more papulated, and the patches often lefs extenfive, fo that to difcriminate with exactnefs, the patient being under two years of age, requires both minute attention, and fome previous habitude."

3. The *Rubeola nigra* is that variety of the meafles, which fometimes occurs, in which, about the feventh or eighth day, the rafh becomes fuddenly black, or of a dark purple colour, with a mixture of yellow. This appearance has continued ten days, and in fome cafes longer, without much diftrefs to the patient, and with no other fymptoms of fever than a quick pulfe, and a flight degree of languor. The mineral acids were adminiftered in thefe cafes with evident advantage. Sydenham afcribes the change of the appearance of the rafh to a black or purple colour, which he occafionally witneffed in adults, to the pernicious perfeverance in a heating regimen. To the influence of fuch a regimen, indeed, he affirms that the pulmonary inflammation, which is the moft fatal fymptom, as well as the diarrhœa, that continued many weeks, was generally to be imputed. See his excellent chapter on Meafles, which contains the prototype of the defcription of the difeafe, that has been given by the majority of fubfequent writers. Sect. iv. cap. 5.

Under the denomination of "putrid meafles," fir Will. Watfon defcribed a difeafe, which prevailed among the children of the Foundling Hofpital, in 1763 and 1768. (See Med. Obf. and Inquir. vol. iv.) On examining the fymptoms of this difeafe, however, as detailed by fir W. Watfon himfelf, as well as the varying appellations, which he gave to it, at different times, in his journal of the cafes, Dr. Willan has fhewn moft clearly, that the difeafe in queftion was not meafles, but fcarlet-fever. There were, indeed, a cough and watery eyes among the fymptoms of thefe "putrid meafles;" but "the eruption appeared over nearly the whole body on the fecond day;"—"the fauces were of a deep red colour;"—"the pulfe was very quick, but low;"—"the patients complained of extreme weaknefs, and could not bear bleeding;"—"their oppreffed and difficult breathing was attended with great reftleffnefs and anxiety, but with fcarce any expectoration throughout;"—"fome died under laborious refpiration, more from a dyfenteric purging;"—"fome cafes terminated in mortification of the rectum, pudenda, cheeks, gums, &c. others with caries of the jawbones." Now thefe circumftances obvioufly belong to fcarlatina, and not to meafles: indeed fir W. Watfon refers them to the morbilli maligni, or epidemii, defcribed by Morton. (De Morbillis et Febre Scarlatina.) But Morton, who calls the difeafe alfo morbilli *fpurii*, exprefsly maintains that the meafles and fcarlatina are the fame difeafe, with no more variation in their form, than there is between the diftinct and confluent fmall-pox: he has therefore conjoined the principal fymptoms (cap. iii.), and wifhes to banifh the diftinction, and the very name of fcarlatina, from medical language. Hence thofe readers who attend not to the names of things, but to the things themfelves as defcribed, will find that the morbilli maligni, epidemii, and fpurii, and the febris morbillofa peftilentialis, in his writings, have no relation to the meafles, but conftitute the difeafe, to which other writers have given the titles of angina maligna, fcarlatina anginofa, and maligna, &c. Willan, loc. cit.

The original writers on the meafles, however, not only laid the foundation for this error, but created a much greater confufion, by defcribing the fmall-pox and the meafles as one and the fame difeafe, which admitted of confiderable variety in its form. This confufion was tranfmitted from the Arabian phyficians, who firft defcribed thefe difeafes, through eight or nine centuries. But as the meafles and fcarlet fever were deemed one and the fame malady, even down to our own times; fo this confufion was greater than at at first sight it appears to have been; inasmuch as these *three* specific contagions were treated of as one disease, including also the chicken-pox, which was separated during the last century. This circumstance enables us to explain the opinion of the Arabian physicians, that the small-pox or measles not unfrequently occurred *twice*, but rarely *thrice*, in the course of the life of an individual; since the occurrence of any one of these four diseases would be considered as a recurrence of the small-pox. It would seem extraordinary, indeed, (if we did not know how completely the observation of mankind is obscured and perverted by pre-conceived opinions,) that the almost universal occurrence of both the small-pox and the measles, in the same individuals, should have escaped their notice. Yet even so late as the time of Sennertus, this fact was not known: for that able and learned physician discusses the question, Why the disease in some constitutions assumes the form of small-pox, and in others that of the measles? (See his Med. Pract. lib. iv. cap. 12.) He refers it merely to some indescribable idiosyncrasy, or peculiarity of habit. In his time, indeed, physicians had not entirely agreed upon the appropriation even of the names *variolæ* and *morbilli*; for some applied the term *variolæ* to the eruption of the measles, "quæ colorem cutis *variant*," they said. Diemerbroeck, an able Dutch professor, still later expressed his opinion, that small-pox and measles differed only casually and in degree, not in kind. "Differunt (morbilli) à variolis accidentaliter, vel quoad magis et minus." Tractat. de Variol. et Morbill. cap. xiv.

When the most able physicians did not step aside from the path which the Arabians had marked out for them, so as to ascertain the essential difference between the *pustular* small-pox and the *rash* called measles, it can scarcely be expected that they should have made out the distinction between the two rashes of measles and scarlatina. It is obvious, however, that the scarlatina was known to them, and they deemed it a variety of measles, as many later writers have done.

There is no trace in medical history of the origin and primary cause of the measles, nor of the other contagious eruptive fevers; but it is commonly supposed, that they had no existence in the time of the older Greek and of the Roman physicians; since, among the accurate descriptions which they have left of many diseases, that are at present familiar to us, no distinct account of these striking and formidable maladies is to be found. This is, indeed, an extraordinary circumstance; and by those who look back to the fathers of physic, as to the only correct and unbiassed observers of nature, it is deemed conclusive evidence on the subject. We have seen above, however, that the most accomplished physicians of later times were for ages blinded by the opinions of their predecessors, so as to overlook the most glaring facts; and it is not necessary to inform the learned reader, that no succession of writers ever displayed a more servile adherence to the doctrines of their ancestors, or composed their works by a more systematic transcription of those which had gone before, than the series of Greek physicians from Galen down to Actuarius; nor has any other class of observers been more enslaved by hypothesis, than the Greeks by the four humours of Hippocrates, and the four qualities which Galen engrafted upon them. Insomuch that they satisfied themselves, with giving general appellations to the eruptions, connected with fevers, which they classed together, as pestilential; and deemed the *anthraces* and carbuncles of the true plague, and the *erysipelata, ecthymata, phlyctænæ, erythemata, exanthemata, herpetes*, &c., under which most probably they included the small-pox, measles, scarlet-fever, nettle-rash, &c., as mere varieties of pestilential fever, arising from different combinations of the four humours. These eruptions are frequently mentioned as accompanying malignant fevers by Hippocrates and Galen.

Farther, it is remarkable, that the first writers (of the Arabian school) who treat of small-pox and measles, do not speak of them as new or unusual diseases. Aaron, a physician of Alexandria, and contemporary with Mahomet, considers them as the result of putridity, and similar to the carbuncles of the groin, axillæ, &c., which were often epidemical in the climate where he resided, and fatal within four or five days. Rhazes, a physician of Bagdad, who, about the middle of the ninth century, collected the observations of his predecessors, in a curious tract on this subject, takes it for granted that the small-pox and measles were known to Galen, more than six hundred years before his own time. Although we may admit, however, that the passages which Rhazes quotes (from an incorrect translation of the works of Galen, and not from the original Greek), do not bear him out in this opinion; yet it is scarcely possible to deny that the diseases in question were known *before* the time of Galen, if we carefully peruse a chapter "de Pustularum (ἐξανθημάτων) in febribus curatione," written by Herodotus, and preserved by Aëtius. (See Aëtii, tetrab. ii. serm. i. cap. 129.) This Herodotus was an eminent physician at Rome, in the reign of Trajan, more than half a century before the arrival of Galen in that city; the fragments of his writings, which have been transcribed by Oribasius and Aëtius, contain so much original observation and perspicuity of description, as to excite a regret that the greater part of them has been lost. Herodotus begins this chapter, by mentioning the herpetic eruptions that break out about the mouth and alæ of the nose, at the termination of catarrhal and other slight fevers. "In febrientibus assiduè fiunt exanthemata circa labia et nasum, juxta febrium solutionem." And he recommends these to be treated with a simple liniment, or a saturnine ointment. "But," he proceeds, "in the beginning of fevers, which are not simple, but the result of vitious humours, there arise *over the whole body* patches like flea-bites; and in malignant and pestilential fevers these ulcerate, and some of them have an affinity with carbuncles. All these eruptions are signs of the redundancy of corrupt and corrosive humours in the habit; but those which appear on the face are the most malignant of all. They are worse if numerous, than if few;—the larger are worse than those which are smaller,—and those which have a short course, than those which remain a long time. Those are more dangerous too which are hot and inflamed, than those which are accompanied by itching. And those again which are conjoined with a costive or gently open state of bowels, are favourable; while those accompanied by diarrhœa and vomiting are dangerous; but if, while the successive eruptions appear, the diarrhœa ceases, it is favourable. These exanthemata are attended by malignant symptoms of fever, and often by syncope." The first species, resembling the flea-bites, (by which he probably means the measles) "are to be treated by blood-letting in the beginning, if nothing contra-indicate that remedy; for if the eruptions be repelled inwards, they are wont to produce danger, unless the acrimony be carried off by vomiting or by stool." Hence he recommends "emollient clysters of ptisan, with egg, and oil of chamomile, and that the evening injection should be retained all night; and likewise a spare diet, quo undique multitudo tollatur." But "at the accession of the disease, on account of the violent pains at the region of the stomach, we order warm water to be given," he says, "and vomiting to be excited, by putting the finger or a feather into the throat; light cooling food, &c. &c." But in those cases where the eruptions are pestilential and carbunculous, "we employ blood-

blood-letting at the very outset, but not abstinence; for fasting renders the matter more malignant, and diminishes the vital powers, which we should support in all fevers, especially pestilential ones." He then tells us, that "the same cerates and plaisters, which are useful in burns, may be applied to the pustules, and that those on the face may be alleviated by washing with warm water." When they ulcerate, he recommends the application of poultices of bread, lentils, &c., boiled with honey; and at the same time a diet of goat's milk, to correct the morbid state of the humours. After the decline of the eruption, a proper purgative is to be administered; and the cure is to be completed by an antidote of theriaca or mithridate, "which may destroy the poisonous relics of the humours."

This account is applicable only to the exanthematic fevers, and especially to the small-pox, including measles and scarlatina; for we are acquainted with no other fevers, "occasionally pestilential, with eruptions over the whole body, that often ulcerate, especially on the face." And it appears from the conclusion of this chapter, that Herodotus was well acquainted with the danger of the confluent, and highly red or livid forms of these eruptions. "Moreover," he says, "those which are extremely red, are of the worst kind; but those which are livid, black, and tumid, like flesh that has been dotted, are still more fatal; and these are abundant on the face and breast, abdomen, sides, and back." His advice as to the conduct of the physician in these desperate cases, is curious. "In such instances it is prudent not to attempt any thing in the beginning, but to wait; for if it terminates ill, the blame will fall upon him, who endeavoured or promised to effect a cure; but if the disease goes on to its acme, without any increase of malignancy, then it should not be altogether left to itself; a little occasional assistance should be given, medicine should be administered at proper opportunities, and the cure be conducted with great vigilance. For those eruptions, which arise from beneath in a mortifying state of the surface, what can they denote but that the life is passing from within?"

It appears pretty obvious, from the preceding extracts, that the contagious exanthemata were familiarly known at Rome, at the end of the first century. For this is the language of observation and experience, and implies that the diseases, thus distinctly described, were of ordinary occurrence; their recent appearance is not once hinted at. If we trace the accounts of these exanthemata, down to the seventeenth century, even after appropriate names had been given to them, we still find a similar communion of nature, origin, and treatment, ascribed to them; and it was not till the end of the 18th century, that their peculiar characteristics were pointed out. The Arabians themselves have distinctly described the scarlatina, as a variety of measles [see Haly Abbas, Theorice. lib. viii. cap. 14. where the translator has distinguished it from the *morbilli* (or ordinary measles) by giving it the appellation of *rubeola*, from its scarlet colour]; yet the disease was still confounded with the measles, so late as the publication of sir W. Watson's paper, above referred to; so difficult it is to see with our own eyes through the veil of prejudice! Consult Rhazes de Variolis et Morbillis, translated by Channing. Sydenham, Obs. Med. sect. iv. chap. 5. Morton, de Morbis acutis, exercit. iii. Sennert. de Febribus, lib. iv. cap. 12. Diemerbroeck de Variol. et Morbill. cap. xiii. Heberden, in Med. Transact. vol. iii., and Commentar. cap. 63.; and Willan on Cutaneous Dis. order iii.

MEASURE, Mensura, in *Geometry*, denotes any certain quantity assumed as one, or unity, to which the ratio of other homogeneous or similar quantities is expressed.

This definition is somewhat more agreeable to practice than that of Euclid, who defines measure a quantity, which being repeated any number of times, becomes equal to another: which only answers to the idea of an arithmetical measure, or quota part.

Measure *of an Angle*, is an arc described from the vertex in any place between its legs. Hence angles are distinguished by the ratio of the arcs, described from the vertex between the legs, to the peripheries.

Angles then are distinguished by those arcs; and the arcs are distinguished by their ratio to the periphery. See Angle.

It is, however, in many cases, a more simple and more convenient method to estimate angles, not by the arcs subtending them, but by their sines, or the perpendicular falling from one leg to the other. Thus it is usual, among miners, to say that the ground rises or falls one foot, or one yard, in ten, when the sine of the angle of its inclination to the horizon is one-tenth of the radius. Angles of different magnitudes are indeed proportional to the arcs, and not to the sines, so that in this sense the sine is not a true measure of the comparative magnitude of the angle; but in making calculations, we are more frequently obliged to employ the sine or cosine of an angle than the angle or arc itself. Nevertheless, it is easy to pass from one of these elements to the other by means either of trigonometrical tables, or of the scales engraved on the sector.

To measure the height of a hill, see Altitude, and the latter part of the article Levelling.

Measure *of a Figure*, or plane surface, is a square; whose side is one inch, foot, yard, or some other determinate length.

Among geometricians, it is usually a rod, called a *square rod*, divided into ten square feet, and the square feet into square digits. Hence square measures. See Mensuration.

Measure *of a Line* is any right line taken at pleasure, and considered as unity.

The modern geometricians use a decempeda, or rod, divided into ten equal parts, called feet. The feet they subdivide into ten digits, the digit into ten lines, &c. This decimal division of the measure was first introduced by Stevinus, probably from the example of Regiomontanus. The index or character of the decempedæ he made 0, that of feet 1, of digits 2, of lines 3, &c. which, because the measure was subdivided in a decuple ratio, were the logarithms of the division. Bayer, in lieu of these, expressed the logarithms by the Roman characters; *v. g.* 5 perches, 4 feet, 3 digits, and 2 lines, he expressed thus; $5^{0}, 4^{\prime}, 3^{\prime\prime}, 2^{\prime\prime\prime}$. It is frequently most commodious to separate the integers, or rods, from the fractions, by a point; thus, instead of $5^{0}, 4^{\prime}, 3^{\prime\prime}, 2^{\prime\prime\prime}$, to write 5.432. F. Noel observes, that, among the Chinese, the decimal division obtains in their common measures, and even in their weights.

Measures, *Line of*. See Line.

Measure *of the Mass*, or *quantity of matter*, in *Mechanics*, is its weight; it being apparent, that all the matter which coheres and moves with a body, gravitates with it: and it being found by experiment, that the gravities of homogeneal bodies are in proportion to their bulks: hence, while the mass continues the same, the absolute weight will be the same, whatever figure it put on: but, as to its specific weight, it varies as the quantity of surface varies. See Weight.

Measure *of a Number*, in *Arithmetic*, is such a number as divides another, without leaving any fraction; thus 9 is a measure of 27.

Measure,

Measure, *Common.* See Common *Measure.*

Measure *of a Solid,* is a cube, whose side is one inch, foot, yard, or other determined length.

Among geometricians, it is sometimes a rod, or perch, called a *cubic perch;* divided into cubic feet, digits, &c. Hence cubic measures, or measures of capacity. See Cube and Mensuration.

Measure *of Velocity,* in *Mechanics,* is the space passed over by a moving body in any given time.

To measure a velocity, therefore, the space must be divided into as many equal parts as the time is conceived to be divided into. The quantity of space answering to such an interval of time, is the measure of the velocity.

Measure, *Universal* and *Perpetual,* is a kind of measure unalterable by time, to which the measures of different nations and ages might be reduced, and by which they might be compared and estimated. Such a measure is very desirable, if it could be attained. Huygens, in his Horol. Oscill. proposes, for this purpose, the length of a pendulum, vibrating seconds, taken from the point of suspension to the point of oscillation. The third part of such a pendulum may be called the horary foot, and serve as a standard to which the measure of all other feet may be referred. Thus, *v. g.* the proportion of the Paris foot to the horary foot would be that of 864 to 881; because the length of three Paris feet is 864 half lines, and the length of a pendulum, vibrating seconds, contains 3 horary feet, or 3 feet $8\frac{1}{2}$ lines, *i. e.* 881 half lines. But this measure, in order to its being universal, supposes, that the action of gravity is every where the same, which is contrary to fact; and, therefore, it would really serve only for places under the same parallel of latitude; and in order to its being perpetual, it supposes that the action of gravity continues always the same in the same place. (See Pendulum.) See also on the subject of a standard of measures, the article Standard, under which head the different modes of ascertaining it will be detailed and discussed.

Measure, in a legal, commercial, and popular sense, denotes a certain quantity or proportion of any thing bought, sold, valued, or the like. It denotes also a vessel of capacity employed in measuring grain and other articles: the fourth part of a peck.

The regulation of weights and measures ought to be universally the same throughout the kingdom, and should, therefore, be reduced to some fixed rule or standard; the prerogative of fixing which was vested, by our ancient law, in the crown. This standard was originally kept at Winchester; and we find, in the laws of king Edgar, cap. 8, near a century before the Conquest, an injunction, that the one measure, which was kept at Winchester, should be observed throughout the realm. With respect to measures of length, our ancient historians (Will. Malm. in Vita Hen. I. Spelm. Hen. I. apud Wilkins, 299.) inform us, that a new standard of longitudinal measure was ascertained by king Henry I. who commanded that the ulna, or ancient ell, which answers to the modern yard, should be made of the exact length of his own arm: and one standard of measures of length being once gained, all others are easily derived from hence; those of greater length by multiplying, those of less by subdividing the original standard. Thus, by the statute, called "Compositio ulnarum et perticarum," $5\frac{1}{2}$ yards make a perch; and the yard is subdivided into 3 feet, and each foot into 12 inches; which inches will be each of the length of 3 grains of barley. The standard of weights was originally taken from corns of wheat, whence the lowest denomination of weights which we have is still expressed by a "grain;" 32 of which are directed by the statute, called "Compositio mensurarum," to compose a pennyweight, of which 20 make an ounce, 12 ounces a pound, and so upwards. Upon these principles the standards were first made; which, being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Westminster, A.D. 1197, it was ordained that there should be only one weight and one measure throughout the kingdom, and that the custody of the assise or standard of weights and measures should be commited to certain persons, in every city and borough. (See Alnager.) In king John's time, this ordinance of king Richard was frequently dispensed with for money (Hoved. A.D. 1201); which occasioned a provision to be made for inforcing it, in the great charters of king John and his son. Stat. 9 Hen. III. c. 25.

The statute of Magna Charta, cap. 25, ordains, that there shall be but one measure throughout England, according to the standard in the exchequer; which standard was formerly kept in the king's palace; and in all cities, market-towns, and villages, it was kept in the churches. (4 Inst. 273.) By 16 Car. I. cap. 19, there is to be one weight and measure, and one yard, according to the king's standard, and whoever shall keep any other weight or measure, whereby any thing is bought or sold, shall forfeit for every offence five shillings. And by 22 Car. II. cap. 8, water measure, (*viz.* five pecks to the bushel,) as to corn or grain, or salt, is declared to be within the statute 16 Car. I. And if any sell grain or salt, &c. by any other bushel, or measure, than what is agreeable to the standard in the Exchequer, commonly called Winchester measure, he shall forfeit 40*s.* &c. (22 Car. II. c. 8. 22 and 23 Car. II. c. 12.) Notwithstanding these statutes, in many places and counties there are different measures of corn and grain; and the bushel in one place is larger than in another; but the lawfulness of it is not well to be accounted for, since custom or prescription is not allowed to be good against a statute. (Dalt. 250.) It is now settled, that no practice or usage can countervail the statutes 22 Car. II. c. 8. 22 and 23 Car. II. c. 12. above cited. 4 Term Rep. 750. 5 Term Rep. 353.

There are three different measures, *viz.* one for wine, one for ale and beer, and one for corn. In the measure of wine, 8 pints make a gallon, 8 gallons a firkin, 16 gallons a kilderkin, half barrel or rundlet, 4 firkins a barrel, 2 barrels a hogshead, 2 hogsheads a pipe, and 2 pipes a tun. (Stat. 15 R. II. c. 4. 11 H. VII. c. 4. 12 H. VII. c. 5.) In a measure of corn 8 pounds or pints of wheat make the gallon, 4 gallons a peck, 4 pecks a bushel, 4 bushels a sack, and 8 bushels a quarter, &c. And in other measure, 3 barley corns in length make an inch, 12 inches a foot, 3 feet a yard, 3 feet and 9 inches an ell, and $5\frac{1}{2}$ yards or $16\frac{1}{2}$ feet, make the perch, pole, or rod. (Stat. 27 Edw. III. c. 10.) Selling by false measure, being an offence by the common law, may be punished by fine, &c. upon an indictment at common law, as well as by statute. See the statute 11 Hen. VII. c. 4. which inflicts particular fines for offences, pillory, &c. The more easy and usual mode of punishment is by levying, on a summary conviction, by distress and sale, the forfeiture imposed by the several acts of parliament adapted to particular frauds.

Measures are various, according to the various kinds and dimensions of the things measured. Hence arise *lineal* or *longitudinal* measures for lines or lengths: *square* measures for areas or superficies: and *solid* or *cubic* measures for bodies and their capacities. All these again are very different in different countries, and in different ages, and even many of them for different commodities. Whence arise

arise other divisions of *domestic* and *foreign* measures, *ancient* and *modern* ones, *dry* and *liquid* measures, &c.

Under this head the reader will find enumerated and exhibited in tables, the various general standing measures, long, square, and cubic, now or heretofore in use, with their proportions and reductions: for particulars we refer to the following heads; as FOOT, DIGIT, ELL, TUN, GALLON, BUSHEL, PERCH, LEAGUE, FURLONG, &c.

MEASURES, *Assay of*. See ASSAY.

MEASURES, *Standard of*. See STANDARD.

The Tables of different Measures, extracted from various Publications, are as follow; beginning with Measures of Length.

TABLE I.—Scripture Long Measures.

								Engl. Feet	Inch. Dec.
Digit								0	0.912
4	Palm							0	3.648
12	3	Span						0	10.944
24	6	2	Cubit					1	9.888
96	24	8	4	Fathom				7	3.552
144	36	12	6	$1\frac{1}{2}$	Ezekiel's reed			10	11.328
192	48	16	8	2	$1\frac{1}{3}$	Arabian Pole		14	7.104
1920	480	160	80	20	$13\frac{1}{3}$	10	Scoenus, measuring line	145	1.104

N. B. There was another span used in the East, equal to $\frac{1}{4}$th of a cubit.

TABLE II.—Grecian Long Measures reduced to English.

												Engl. Paces.	Feet.	Inch. Dec.
Dactylus, Digit												0	0	$0.7554\frac{11}{10}$
4	Doron, Dochme, Palesta,											0	0	$3.0218\frac{3}{4}$
10	$2\frac{1}{2}$	Lichas										0	0	$7.5546\frac{7}{8}$
11	$2\frac{3}{4}$	$1\frac{1}{10}$	Orthodoron									0	0	$8.3101\frac{9}{11}$
12	3	$1\frac{1}{5}$	$1\frac{1}{11}$	Spithame								0	0	$9.0656\frac{1}{4}$
16	4	$1\frac{6}{10}$	$1\frac{5}{11}$	$1\frac{1}{3}$	Pous foot,							0	1	0.0875
18	$4\frac{1}{2}$	$1\frac{4}{5}$	$1\frac{2}{11}$	$1\frac{1}{2}$	$1\frac{1}{8}$	Pygme, cubit						0	1	$1.5984\frac{3}{8}$
20	5	2	$1\frac{9}{11}$	$1\frac{2}{3}$	$1\frac{1}{4}$	$1\frac{1}{9}$	Pygon					0	1	$3.109\frac{3}{8}$
24	6	$2\frac{2}{5}$	$2\frac{2}{11}$	2	$1\frac{1}{2}$	$1\frac{1}{3}$	$1\frac{1}{5}$	Pecus, cubit larger				0	1	6.13125
96	24	$9\frac{3}{5}$	$8\frac{8}{11}$	8	6	$5\frac{1}{3}$	$4\frac{4}{5}$	4	Orgya, pace			0	6	0.525
9600	2400	960	$872\frac{8}{11}$	800	600	$533\frac{1}{3}$	480	400	100	Stadium Aulus > furlong		100	4	4.5
76800	19200	7680	$6981\frac{9}{11}$	6400	4800	$4266\frac{2}{3}$	3840	3200	800	8	Million, Mile	805	5	0

N. B. Two sorts of long measures were used in Greece, *viz.* the Olympic and the Pythic. The former was used in Peloponnesus, Attica, Sicily, and the Greek cities in Italy. The latter was used in Thessaly, Illyria, Phocis, and Thrace, and at Marseilles in Gaul.

The Olympic foot, properly called Greek, according to	Dr. Hutton, contains		12.108 English inches,
	Folkes	—	12.072
	Cavallo	—	12.084
The Pythic foot, called also natural foot, according to	Hutton	—	9.768
	Pauċton	—	9.731

Hence it appears, that the Olympic stadium is $201\frac{1}{2}$ English yards, nearly; and the Pythic or Delphic stadium, $162\frac{1}{2}$ yards, nearly; and the other measures in proportion.

The Phyleterian foot is the Pythic cubit, or $1\frac{1}{2}$ Pythic foot. The Macedonian foot was 13.92 English inches; and the Sicilian foot of Archimedes, 8.76 English inches. See TABLE VII.

TABLE III.—Jewish Long or Itinerary Measures.

						Eng. Miles.	Paces.	Feet.Dec.
Cubit						0	0	1.824
400	Stadium					0	145	4.6
2000	5	Sab. day's journey				0	729	3.0
4000	10	2	Eastern mile			1	403	1.0
12000	30	6	3	Parasang		4	153	3.0
96000	240	48	24	8	A day's journey	33	172	4.0

TABLE IV.—Roman Long Measures reduced to English.

										Engl. Paces.	Feet.	Inch.Dec.
Digitus transversus										0	0	$0.725\frac{3}{4}$
$1\frac{1}{3}$	Uncia, or Inch									0	0	0.967
4	3	Palma minor								0	0	2.901
16	12	4	Pes, or Foot							0	0	11.604
20	15	5	$1\frac{1}{4}$	Palmipes						0	1	2.505
24	18	6	$1\frac{1}{2}$	$1\frac{1}{5}$	Cubitus					0	1	5.406
40	30	10	$2\frac{1}{2}$	2	$1\frac{2}{3}$	Gradus				0	2	5.01
80	60	20	5	4	$3\frac{1}{3}$	2	Passus			0	4	10.02
10000	7500	2500	625	500	$416\frac{2}{3}$	250	125	Stadium		120	4	4.5
80000	60000	20000	5000	4000	$3333\frac{1}{3}$	2000	1000	8	Milliare	967	0	0

N.B. The Roman measures began with 6 scrupula = 1 sicilicum; 8 scrupula = 1 duellum; $1\frac{1}{2}$ duellum = 1 seminaria; and 18 scrupula = 1 digitus. Two passus were equal to 1 decempeda.

TABLE V.—Proportions of several long Measures to each other, by M. Picard.

The Rhinland or Leyden foot (12 whereof make the Rhinland perch) supposed	696
The English foot	$675\frac{1}{2}$
The Paris foot	720
The Amsterdam foot, from that of Leyden, by Snellius	629
The Danish foot (two whereof make the Danish ell)	$701\frac{8}{10}$
The Swedish foot	$658\frac{1}{4}$
The Brussels foot	$609\frac{3}{5}$
The Dantzick foot, from Hevelius's Selenographia	636
The Lyons foot, by M. Auzout	$757\frac{2}{3}$
The Bologna foot, by the same	843
The braccio of Florence, by the same, and father Mersenne	1290
The palm of the architects at Rome, according to the observations of Messrs. Picard and Auzout	$494\frac{2}{4}$
The Roman foot in the Capitol, examined by Messrs. Picard and Auzout	653 or $653\frac{1}{2}$
The same from the Greek foot	652
From the vineyard Mattei	$657\frac{1}{2}$
From the palm	$658\frac{1}{4}$
From the pavement of the Pantheon, supposed to contain 10 Roman feet	653
From a slip of marble in the same pavement, supposed to contain 3 Roman feet	650
From the pyramid of Cestius, supposed to contain 95 Roman feet	$653\frac{1}{2}$
From the diameters of the columns in the arch of Septimius Severus	$653\frac{1}{3}$
From a slip of porphyry in the pavement of the Pantheon	$653\frac{1}{3}$

See on this subject Phil. Transf. vol. li. art. 69. p. 774.
For other measures, see FOOT.

TABLE VI.—Proportions of the long Meaſures of ſeveral Nations to the Engliſh Foot, taken from Meſſrs. Greaves, Auzout, Picard, and Eiſenchmid.

The Engliſh ſtandard foot being divided into 1000 equal parts, the other meaſures will have the proportions to it which follow:

	Feet.	Inches.
Engliſh foot	1000	12
Paris foot	1068	12.816
Venetian foot	1162	13.944
Rhinland foot	1033	12.396
Straſburg foot	952	11.424
Norimberg foot	1000	12
Dantzick foot	944	11.328
Daniſh foot	1042	12.504
Swediſh foot	977¾	11.733
Derahor cubit of Cairo	1824	21.888
Perſian ariſh	3197	38.364
Greater Turkiſh pike	2200	26.4
Leſſer Turkiſh pike	2131	25.572
Braccio at Florence	1913	22.956
Braccio for woollen at Sienna	1242	14.904
Braccio for linen at Sienna	1974	23.688
Canna at Naples	6880	82.56
Vera at Almeria and Gibraltar	2760	33.12
Palmo di Archtetti at Rome	7320	87.84
Fanna di Archtetti	7320	87.84
Palmo di bracchio di mercantia	695½	8.346
Genoa palm	815	9.78
Bolognian foot	1250	15
Antwerp ell	2283	27.396
Amſterdam ell	2268	27.216
Leyden ell	2260	27.12
Paris draper's ell	3929	47.148
Paris mercer's ell	3937	47.244

TABLE VII.—Ancient Meaſures taken from Folkes, Raper, Shuckburgh, Hutton, Cavallo, and others.

Arabian, foot	1.095	Engl. H.
Babylonian, foot	1.144	H.
	1.135	H.
Druſian, foot	1.090	H.
Egyptian, foot	1.421	H.
Egyptian, ſtadium	730.8	
Greek, foot	1.009	H.
	1.006 / 1.007	Folkes, 1 $\frac{1}{24}$ Roman f.
	1.007	C.
Greek, phyleterian foot	1.167	H.
Hebrew, foot	1.212	H.
Hebrew, cubit	1.817	H.
Hebrew, ſacred cubit	2.002	H.
Hebrew, great cubit = 6 common cubits. H.		
Macedonian, foot	1.160	H.
Natural foot	.814	H.
Ptolemaic = Greek foot		H.
Roman, foot	.970	Bernard.
	.967	Picard and Greaves.
	.966 / .967	Folkes.
Roman, foot	.970	before Titus. Raper.
	.965	after Titus. Raper.
	.9672	from rules. Sh.
	.9681	from buildings. Sh.
	.9696	from a ſtone. Sh.
	.967	H.
Roman mile of Pliny	4840.5	C.
Roman mile of Strabo	4903.	
Sicilian foot of Archimedes	.730	H.

The length of the Roman foot in inches is ſtated as follows:

By Bernard	11.640 Engliſh inches.
By Picard and Hutton	11.604
By Folkes	11.592
By Raper (before Titus)	11.640
By the ſame (after Titus)	11.580
By Schuckburgh, from rules	11.6064
By the ſame, from buildings	11.6172
By the ſame, from a tomb-ſtone	11.6352

N.B. Hence, 11.6 Engliſh inches ſeem to be a medium; and, therefore, the Roman mile = 1611 Engliſh yards, being 149 yards leſs than the Engliſh mile. See FOOT.

TABLE VIII.—Ancient Greek ſuperficial Meaſures.

Olympic Land Meaſure.

36	Olympic ſquare feet	=	1 Hexapodon.
6	Hexapoda	=	1 Hemihectos.
2	Hemihecti	=	1 Hectos or Modius.
6	Modii	=	1 Medimnus or Jugerum.

Hence it appears, that the Olympic jugerum was equal to 103 Engliſh perches, or nearly $\frac{5}{8}$ths of an acre.

Pythic Land Meaſure.

1666⅔	Square cubits	=	1 Hemihectos.
2	Hemihecti	=	1 Modius.
6	Modii	=	1 Medimnus or Jugerum.

Hence the Pythic jugerum appears to have been equal to 109 Engliſh perches, or nearly $\frac{11}{16}$ths of an acre.

N.B. The plethron, or acre, is ſaid by ſome to contain 1444, by others 10,000 ſquare feet; and aroura, the half of the plethron. The aroura of the Egyptians was the ſquare of 100 cubits.

TABLE IX.—Ancient Greek Corn Meaſure.

2	Xeſtes	=	1 Chœnix.
4	Chœnices	=	1 Hemihectos.
1½	Hemihectos	=	1 Tetarlon.
2	Hemihecti	=	1 Modius.
6	Modii	=	1 Medimnus or Achana.

Paucton ſtates the medimnus to have been 3½ French boiſſeaux = 1.27 Engliſh buſhels, and the inferior meaſures in proportion.

TABLE X.—Attic Dry Meafures reduced to Englifh.

							Pecks.	Gall.	Pints.	Sol. Inch.
Cochliarion							0	0	0	0.276 $\frac{1}{6}$
10	Cyathus						0	0	0	2.763 $\frac{1}{2}$
15	$1\frac{1}{2}$	Oxybaphon					0	0	0	4.144 $\frac{2}{4}$
60	6	4	Cotylus				0		0	16.579
120	12	8	2	Xeftes, fextary			0	0	0	33.158
180	18	12	3	$1\frac{1}{2}$	Chœnix		0	0	1	15.705 $\frac{1}{2}$
8640	864	576	144	72	48	Medimnus	4	0	6	3.5[illegible]1

TABLE XI.—Attic Meafures of Capacity for Liquids, reduced to the Englifh Wine Meafure.

										Gall.	Pints.	Sol. Inch. Dec.
Cochliarion										0	$\frac{1}{120}$	0.0356 [illegible]
2	Cheme									0	$\frac{1}{60}$	0.0712 $\frac{1}{5}$
$2\frac{1}{2}$	$1\frac{1}{4}$	Myfton								0	$\frac{1}{48}$	0.089 $\frac{1}{4}$
5	$2\frac{1}{2}$	2	Concha							0	$\frac{1}{24}$	0.178 $\frac{11}{24}$
10	5	4	2	Cyathus						0	$\frac{1}{12}$	0.356 $\frac{11}{21}$
15	$7\frac{1}{2}$	6	3	$1\frac{1}{2}$	Oxybaphon					0	$\frac{1}{8}$	0.535 $\frac{3}{8}$
60	30	24	12	6	4	Cotylus				0	$\frac{1}{2}$	2.141 $\frac{1}{2}$
120	60	48	24	12	8	2	Xeftes, fextary			0	1	4.283
720	360	288	144	72	48	12	6	Chous, congius		0	6	25.698
8640	4320	3456	1728	864	576	144	7	12	Metretes, amphora	10	2	19.626

Others reckon 6 choi = 1 amphoreus, and 2 amphorei = 1 keramion or metretes. The keramion is ftated by Paucton o have been equal to 35 French pints, or $8\frac{3}{4}$ Englifh gallons, and the other meafures in proportion.

TABLE XII.—Meafures of Capacity for Liquids, reduced to Englifh Wine Meafure.

										Gall.	Pints.	Sol. Inch. Dec.
Ligula										0	$\frac{1}{48}$	0.117 $\frac{5}{12}$
4	Cyathus									0	$\frac{1}{12}$	0.469 $\frac{2}{3}$

Table XV.—Ancient Roman Land Measure.

100 Square Roman feet	=	1	Scrupulum of land
4 Scrupula	=	1	Sextulus
1$\frac{1}{5}$ Sextulus	=	1	Actus
6 Sextuli or 5 Actus	=	1	Uncia of land
6 Unciæ	=	1	Square Actus
2 Square Actus	=	1	Jugerum
2 Jugera	=	1	Heredium
100 Heredia	=	1	Centuria

N. B. The actus was a slip of ground four Roman feet broad, and 120 long. The jugerum or acre was considered as an integer, and divided, like the libra or as, in the following manner:

		Unciæ	Jugerum contained: Square Feet.	Scrup.	Eng. Roods.	Sq. Pol.	Sq. Feet.
1	As	12 As	28800	288	2	18	250.05
$\frac{11}{12}$	Deunx	11 Deunx	26400	264	2	10	183.85
$\frac{5}{6}$	Dextans	10 Dextans	24000	240	2	2	117.64
$\frac{3}{4}$	Dodrans	9 Dodrans	21600	216	1	34	51.42
$\frac{2}{3}$	Bes	8 Bes	19200	192	1	25	257.46
$\frac{7}{12}$	Septunx	7 Septunx	16800	168	1	17	191.25
$\frac{1}{2}$	Semis	6 Semis	14400	144	1	9	125.03
$\frac{5}{12}$	Quincunx	5 Quincunx	12000	120	1	1	58.82
$\frac{1}{3}$	Triens	4 Triens	9600	96	0	32	264.85
$\frac{1}{4}$	Quadrans	3 Quadrans	7200	72	0	24	198.64
$\frac{1}{6}$	Sextans	2 Sextans	4800	48	0	16	132.43
$\frac{1}{12}$	Uncia	1 Uncia	2400	24	0	8	66.21

N. B. If we take the Roman foot at 11.6 English inches (see Table VII.), the Roman jugerum was 5980 English square yards, or 1 acre 37$\frac{1}{2}$ perches.

TABLE XVI.—Roman Dry Meaſures reduced to Engliſh.

Measure	Ligula	Cyathus	Acetabulum	Hemina or Trutta	Sextarius	Semi d.	Peck.	Gall.	Pints.	Sol. Inch. Dec.
Ligula							0	0	$0\frac{1}{48}$	0.01
Cyathus	4						0	0	$0\frac{1}{12}$	0.04
Acetabulum	6	$1\frac{1}{2}$					0	0	$0\frac{1}{8}$	0.06
Hemina or Trutta	24	6	4				0	0	$0\frac{1}{2}$	0.24
Sextarius	48	12	8	2			0	0	1	0.48
Semi d.	384	96	64	16	8		0	1	0	3.84
Modius	768	192	108	32	16	2	1	0	0	7.68

TABLE XVII.—Ancient Roman Liquid Meaſures.

6 Sextarii	= 1 Congius
4 Congii	= 1 Urna
2 Urnæ	= 1 Amphora
20 Amphoræ	= 1 Dolium.

N. B. The ſextarius and its diviſions were uſed as in the preceding table. If the ſextarius be, as above ſuppoſed, = 36.94 Engliſh cubic inches, the amphora will be = $7\frac{1}{2}$ Engliſh gallons, and the dolium = $153\frac{1}{3}$ Engliſh gallons.

The principal modern meaſures will be found either in the following tables, or under the names of the countries and towns in which they are uſed, or under their own appropriate titles.

TABLE XVIII.—Engliſh Long Meaſures, or Meaſures of Application.

Measure	Barley-corn	Inch	Palm	Span	Foot	Cubit	Yard	Pace	Fathom	Pole, or Rod	Furlong
Barley-corn											
Inch	3										
Palm	9	3									
Span	27	9	3								
Foot	36	12	4	$1\frac{1}{3}$							
Cubit	54	18	6	2	$1\frac{1}{2}$						
Yard	108	36	12	4	3	2					
Pace	180	60	20	$6\frac{2}{3}$	5	$3\frac{1}{3}$	$1\frac{2}{3}$				
Fathom	216	72	24	8	6	4	2	$1\frac{1}{5}$			
Pole, or Rod	594	198	66	22	$16\frac{1}{2}$	11	$5\frac{1}{2}$	$3\frac{3}{10}$	$2\frac{3}{4}$		
Furlong	23760	7920	2640	880	660	440	220	132	110	40	
Mile	190080	63360	21120	7040	5280	3520	1760	1056	880	320	8

N. B. To the above meaſures we may add a link = 7.92 inches, a chain = 792, a nail of cloth = $2\frac{1}{4}$, a quarter = 9, an ell = 45, and a hand = 4 inches.

TABLE XIX.—Scotch Long Meaſures.

An Ell	= 37.2	Engliſh inches.
A Fall	= 223.2	
A Furlong	= 8928	
A Mile	= 71424	
A Link	= 8.928	
A Chain, or Short Rood	= 892.8	
A Long Rood	= 1339.2	

TABLE

Table XX.—English Square or Superficial Measures.

Inches	Feet	Yards	Paces	Poles	Rood	Acre
144						
1296	9					
3600	25	$2\frac{7}{9}$				
39204	$272\frac{1}{4}$	$30\frac{1}{4}$	10.89			
1568160	10890	1210	435.6	40		
6272640	43560	4840	1743.6	160	4	

N. B. English square or superficial measures are raised from the yard of 36 inches, multiplied into itself; and this producing 1296 square inches in the square yard, the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the table. The Scotch acre is 55353.6 square feet English, or 1.27 English acre. See Acre.

Table XXI.—English Dry or Corn Measures.

Solid Inches	Pint	Gallon	Peck	Winchester Bushel	Strike	Carnock or coom	Seam or quarter	Weigh	Last
$34\frac{1}{12}$									
$272\frac{1}{4}$	8								
$544\frac{1}{2}$	16	2							
2178	64	8	4						
	128	16	8	2					
	265	32	16	4	2				
17424	512	64	32	8	4	2			
	3072	384	192	48	24	12	6		
	5120	640	320	80	40	20	10	$1\frac{2}{3}$	

But if the corn gallon contain only 268.8 solid inches, the measures will be as follows:

Solid inches	Gallon	Peck	Winchester bushel *	Quarter
268.8				
537.6	2			
2150.42	8	4		
17203.36	64	32	8	

According to this estimate of the corn gallon, the pint will be 33.6 solid or cubic inches, a quart = 67.2, a pottle = 134.4.

* A heaped bushel is one-third more.

N. B. Some make five quarters a weigh or load, and two weighs a last of wheat; and others reckon ten quarters to the weigh, and twelve weighs to the last. A bushel of wheat, at a mean, weighs 60 pounds, of barley 50, of oats 38; a chaldron of coals is 36 heaped bushels, weighing about 2988 pounds. See Chaldron.

English

English dry or corn measures are raised from the Winchester gallon, which contains $272\frac{1}{4}$ solid inches, and is to hold of pure running or rain-water, nine pounds, thirteen ounces. This seems to stand on the foot of the old wine gallon, of 224 cubic inches; 12 being to $14\frac{13}{16}$, as 224 to $272\frac{1}{4}$. Yet by act of parliament, made 1697, it is decreed, that a round bushel, eighteen inches and a half wide, and eight deep, is a legal Winchester bushel. But such a vessel will only hold 2150.42 cubic inches: and consequently the gallon will contain $268\frac{4}{5}$ cubic inches. The divisions and multiples are in the preceding table.

TABLE XXII.—English Measures of Capacity of Liquids.

Wine Measure.

Solid or Cubic Inches.

28.875	Pint								
231	8	Gallon							
4158	144	18	Rundlet

15228	432	54	6	3	$1\frac{1}{2}$	Hogshead	
30456	864	108	12	6	3	2	Butt

English

English liquid meafures were originally raifed from troy weight; it being enacted by feveral ftatutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, fhould weigh a gallon of wine meafure; the divifions and multiples whereof were to form the other meafures: at the fame time it was alfo ordered, that there fhould be but one liquid meafure in the kingdom; yet cuftom has prevailed; and there having been introduced a new weight, *viz.* the avoirdupois, we have now a fecond ftandard gallon adjufted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter ftandard are raifed two feveral meafures, the one for ale, the other for beer. For the method of reducing one into the other, fee WEIGHT.

The fealed gallon at Guildhall, which is the ftandard for wines, fpirits, oils, &c. is fuppofed to contain 231 cubic inches; and, on this fuppofition, the other meafures raifed therefrom will contain as in the preceding tables; yet, by actual experiment made in 1688, before the lord mayor and the commiffioners of excife, this gallon was only found to contain 224 cubic inches; it was however agreed to continue the common fuppofed contents of 231 cubic inches; fo that all computations ftand on their old footing. Hence, as 12 is to 231, fo is $14\frac{12}{20}$ to $281\frac{1}{2}$, the cubic inches in the ale gallon: but in effect the ale quart contains $70\frac{1}{2}$ cubic inches; on which principle the ale and beer gallon will be 282 cubic inches. See on this fubject Phil. Tranf. vol. xlvi. art. 15. p. 54.

The feveral divifions and multiples of thefe meafures and their proportions, are exhibited in the preceding tables.

It is conjectured, that fome centuries before the conqueft, a cubic foot of water weighing 1000 ounces, 32 cubic feet weighed 2000 pounds, or a ton; that the fame quantity was a ton of liquids, and a hogfhead eight cubic feet, or 13824 cubic inches, one fixty-third of which was 219.4 inches, or a gallon. A quarter of wheat was a quarter of a ton, weighing about 500 pounds, a bufhel one-eighth of this, equivalent to a cubic foot of water. A chaldron of coals was a ton, and weighed 2000 pounds. (Barlow, Phil. Tranf. for 1740.) At prefent 12 wine gallons of diftilled water weigh exactly 100 pounds avoirdupois.

Whereas it has been thought expedient that the quantities to be returned as and for a barrel of beer or ale brewed by the common brewer and the allowances for wafte fhould be in all places the fame, it is enacted that after the 5th day of July, 1803, every thirty-fix gallons of beer or ale brewed by the common brewers in Great Britain, whether within the weekly bills of mortality or without the fame, taken according to the ftandard of the ale-quart, four thereof to the gallon in the exchequer, fhall be reckoned and returned by the guager or other officer of excife for a barrel of beer or ale; and the allowances to be made in Great Britain to the common brewer not felling beer ale or worts in any lefs quantity than the whole cafk, containing $4\frac{1}{2}$ gallons, whether within or without the faid limits, for wafte by fillings and leakage, or otherwife, out of the returns by the gagers or other officers, fhall be three barrels upon every thirty-fix barrels, both of ftrong beer, or table beer and ale, and after that rate for any greater or lefs quantity. 43 Geo. III. c. 69.

TABLE XXIII.—Scotch Meafures of Capacity of Liquids.

A Gill is	6.462 Englifh cubic inches.
A Mutchkin	25.85
A Choppin	51.7
A Pint	103.4
A Quart	206.8
A Gallon	827.23
A Hogfhead	13235.7, or 16 gallons.

N.B. By the Act of Union, twelve Scotch gallons are reckoned equal to an Englifh barrel, or 9588 cubic inches, inftead of 9927.

A lippie or feed is 200.345 cubic inches.

TABLE XXIV.—French Meafures, according to the Old Syftem before the Revolution.

A Point is	.0148025 Englifh inch, or nearly $\frac{2}{135}$.
A Line	.088815, or nearly $\frac{6}{90}$.
An Inch or Pouce	1.06578, or $\frac{1}{.938226}$, or $\frac{81}{76}$.
A Foot	12.78933
An Ell or Aune	46.8947, or 44 French inches, or according to Vega, 43.9
A Sonde	63.9967, or 5 French feet, about $\frac{8}{9}$ Englifh fathom.
A Toife or Fathom	76.7360, or 6 French feet; formerly 76.71, Phil. Tranf. for 1742.
A Perche	230.2080, or 18 French feet.
A Perche, mefure royale	22 French feet.
A League	2282 toifes, or $\frac{1}{25}$ of a degree.
A Square Inch	1.13582 Englifh fquare inches.
An Arpent	100 fquare perches, about $\frac{5}{6}$ acre Englifh, ufed near Paris.
An Arpent, mefure royale	about $1\frac{1}{4}$ Englifh acre.
A Cubic Inch	1.21063 cubic inches Englifh.
A Litron	65.34
A Boiffeau	1045.44, or 16 litrons.
A Minot	2090.875, or 3 boiffeaux, nearly an Englifh bufhel.
A Mine	4181.75, or 2 minots.
A Septier	8363.5, or 2 mines, or 6912 inches French.
	double for oats.
A Muid	100362, or 12 feptiers.

N.B. A ton of fhipping contains 42 cubic feet. The aune or ell of Paris varies, being for filk ftuffs 527.5 lines, or $46\frac{17}{20}$ Englifh inches; for woollens, 526.4 French lines, or $46\frac{3}{4}$ Englifh inches; for linens, 524 French lines, or $46\frac{11}{20}$ Englifh inches; and it varies ftill more in other parts of France. The perch, which determines the meafure of the acre, varies in different parts of the country: but the arpent of wood-land is every where the fame, the perch being 22 feet long; and this arpent contains 48,400 French fquare feet, or 6108 Eng. fquare yards, or one acre, one rood, one perch.

2

perch. The arpent for cultivated land, in the vicinity of Paris, contains 900 square toises, or 4088 English yards, so that 43 such arpents are equal to 38 English acres nearly.

TABLE XXV.—French Measures, according to the New System, with the amended Nomenclature of Dr. Young.

Measures of Length.

	English Inches.
Millimetre - - - - -	.03937
Centimetre - - - - -	.39371
Decimetre - - - - -	3.93710
Metre - - - -	39.37100, or 3.281 feet, or 1.09364 yds. or nearly 1 y. 1¼ nail, or 443.2959 French lines, or .513074 toise.
Decametre - - - -	393.71000, or 10 yards, 2 feet, 9.7 inches.
Hecatometre - - -	3937.10000, or 100 yards, 1 foot, 1 inch.
Chiliometre - - -	39371.00000, or 4 furl. 213 yards, 1 foot, 10.2 inches: so that 8 chiliometres are nearly 5 miles.
Myriometre - - -	393710.0000, or 6 miles, 1 furl. 136 yds. 0 f. 6 inch.

N. B. An inch is .0254 metres; 2441 inches 62 metres, 1000 feet nearly 305 metres.

Superficial or Square Measures.

Are, a square decametre, is - -	3.95 Eng. perches, or 119.6046 square yards.
Decare - - - - -	1196.0460 square yards.
Hecatare - - - -	11960.4600 square yards, or 2 acres, 1 rood, 35.4 perches.

Measures of Capacity.

	Cubic Inches English.
Millilitre - - - - -	.06103
Centilitre - - - - -	.61028
Decilitre - - - - -	6.10280
Litre, a cubic decimetre - - -	61.02800, or 2.113 wine pints.
Decalitre - - - - -	610.28000, or 2.64 wine gallons.
Hecatolitre - - - -	6102.80000, or 3.5317 cubic feet, or 26.4 wine gallons.
Chiliolitre - - -	61028.00000, or 35.3170 cubic feet, or 1 tun, 12 wine gallons.
Myriolitre - - - -	610280.00000, or 353.1700 cubic feet.

Solid Measure.

	Cubic Feet.
Decistre, for fire wood - -	3.5317
Stere, a cubic metre - -	35.3170
Decastere - - - - -	353.1700

N. B. In order to express decimal proportions in this new system, the following terms have been adopted. The term *Deca* prefixed denotes 10 times; *Heca*, 100 times; *Chilo*, 1000 times; and *Myrio*, 10,000 times. On the other hand, *Deci* expresses the 10th part; *Centi*, the 100dth part; and *Milli*, the 1000dth part: so that *Decametre* signifies 10 metres; and a *Decimetre*, the 10th part of a metre, &c. &c. The *Metre* is the element of long measures; *Are*, that of square measures; *Stere*, that of solid measures: the *Litre* is the element of all measures of capacity; and the *Gramme*, which is the weight of a cubic centimetre of distilled water, is the element for all weights. (See WEIGHT.) For the principle on which this system of measures is founded, see STANDARD. See Dr. Young's Philos. vol. ii. Kelly's Un. Cambist. vol. ii.

Dr. Kelly, always actuated by a defire of promoting literature and fcience, has, with a polite attention, which we thus refpectfully acknowledge, allowed us to extract feveral of the preceding tables from his very valuable work, the "Univerfal Cambift:" a work which is planned with judgment, and executed, at the expence of much time and labour, with accuracy, and which will be no lefs acceptable and ufeful to men of fcience in general, than to mercantile perfons in particular.

Measures *ufed by different artificers* are 144 fquare inches = a fquare foot, 9 fquare feet = a fquare yard, 63 fquare feet = 7 fquare yards = a rood, 100 fquare feet = a fquare, and 272¼ fquare feet = 30¼ fquare yards = a rod, perch, or fquare pole.

Measure *of fire-wood.* See Cord *of wood.*

Measure *for Horfes.* See Hand.

Measure is alfo ufed to fignify the cadence and time obferved in poetry, dancing, and mufic, to render them regular and agreeable.

The different meafures or metres, in poetry, are the different manners of ordering and combining the quantities, or the long and fhort fyllables. Thus hexameter, pentameter, iambic, fapphic verfes, &c. confift of different meafures. In Englifh verfes, the meafures are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleafes. The moft ufual are, the heroic, generally confifting of five long, and five fhort fyllables; and verfes of four feet; and of three feet and a cæfura, or fingle fyllable.

The ancients, by varioufly combining and tranfpofing their quantities, made a vaft variety of different meafures. Of words, or rather feet, of two fyllables, they formed a fpondee, confifting of two long fyllables; a pyrrhic, of two fhort fyllables; a trochee, of a long and a fhort fyllable; and an iambic, of a fhort and a long fyllable.

Of their feet of three fyllables, they formed a moloffus, confifting of three long fyllables; a tribrach, of three fhort fyllables; a dactyl, of one long and two fhort fyllables; and an anapæft, of two fhort and one long fyllable. The Greek poets contrived a hundred and twenty-four different combinations or meafures, under as many different names, from feet of two fyllables to thofe of fix. See Metre and Prosody.

Measure, in *Mufic*, the interval, or fpace of time, which the perfon who beats time, takes between the raifing and falling of his hand or foot, in order to conduct the movement, fometimes quicker, and fometimes flower, according to the kind of mufic, or the fubject that is fung or played.

The meafure is that which regulates the time we are to dwell on each note. See Time.

The ordinary or common meafure is one fecond, or fixtieth part of a minute, which is nearly the fpace between the beats of the pulfe or heart; the fyftole or contraction of the heart anfwering to the elevation of the hand; and its diaftole, or dilatation, to the letting it fall. The meafure ufually takes up the fpace that a pendulum, of two feet and a half long, employs in making a fwing or vibration. The meafure is regulated according to the different quality or value of the notes in the piece; by which the time, that each note is to take up, is expreffed. The femi-breve, for inftance, holds one rife, and one fall; and this is called the *meafure*, or *whole meafure*; fometimes the *meafure-note*, or *time-note*; the minim, one rife, or one fall; and the crotchet, half a rife, or half a fall, there being four crotchets in a full meafure.

Measures, *Mufical*, are now much fimplified, compared with thofe which our anceftors *defcribed*, we cannot fay *ufed*, as fome of them are impracticable. In the mufical MS. of Waltham holy-crofs, in the poffeffion of the marquis of Lanfdowne,

downe, N° 9, by Chiliton, we have not only double and triple proportions, but quintuple, ſeſquialterate, and ſeſquioctavan; that is, when one minim in the baſe is as long as a ſemibreve, or two minims in the treble; as three minims; as five; as one and a half; as 16 to 12, or 12 to 9.

Whether all theſe meaſures were ever received in practical muſic, does not appear; but we can be very certain, if they were, that the reſult would be nothing but diſlocation and confuſion.

All meaſures and ſpecies of time in modern muſic are reduced to two proportions; the *binary*, *dual*, or *even meaſure*, in which the riſe and fall of the hand are equal; and the *ternary*, *triple*, or *odd* meaſure, in which the fall is double to the riſe. The firſt, uſually called *common time*, is the meaſure conſiſting of two ſemibreves, two minims, or two crotchets; the ſecond, or *triple time*, of three minims, three crotchets or three quavers.

To this purpoſe the number 3 is placed at the beginning of the lines, when the meaſure is intended to be triple; and a C, when the meaſure is to be common or double. This riſing and falling of the hands was called by the Greeks αρσις and θεσις. St. Auguſtine calls it *plauſus*, and the Spaniards *compas*. See Arsis and Thesis.

There is likewiſe a mixed or compound meaſure of 6 or 12 crotchets or quavers in a bar, indicated at the beginning of a movement, thus: $\frac{6}{4}$, or $\frac{12}{4}$, $\frac{9}{4}$, or $\frac{6}{8}$. But as all theſe meaſures move in triplets, for each portion of a bar, they are reducible to binary and ternary meaſures.

Measures, *Powder*, in *Artillery*, are made of copper, and contain from an ounce to twelve pounds: theſe are very convenient in a ſiege, when guns or mortars are loaded with looſe powder, eſpecially in ricochet firing, &c.

MEASURING, Mensuration, defined *geometrically*, is the aſſuming any certain quantity, and expreſſing the proportion of other ſimilar quantities to the ſame.

Measuring, defined *popularly*, is the uſing of a certain known meaſure, and determining thereby the preciſe extent, quantity, or capacity of any thing.

Meaſuring, in the general, makes the practical part of geometry. See Mensuration.

From the various ſubjects on which it is employed, it acquires various names, and conſtitutes various arts. Thus,

Measuring *of Lines*, or quantities of one dimenſion, we call *longimetry*; and when thoſe lines are not extended parallel to the horizon, *altimetry*. When the different altitudes of the two extremes of the lines are alone regarded, we call it *levelling*.

Measuring *of Superficies*, or quantities of two dimenſions, is variouſly denominated, according to its ſubjects: when converſant about lands, it is called *geodeſia*, or *ſurveying*: in other caſes, it is called ſimply *meaſuring*. The inſtruments uſed are the ten-foot rod, chain, compaſs, circumferentor, &c.

Measuring *of Solids*, or quantities of three dimenſions, we call *ſtereometry*; where it is converſant about the capacities of veſſels, or the liquors they contain particularly, *gauging*.

The inſtruments for this art are the gauging-rod, ſliding-rule, &c.

From the definition of meaſuring, where the meaſure is expreſſed to be ſimilar or homogeneous to, *i. e.* of the ſame kind with, the thing meaſured, it is evident, that in the firſt caſe, or in quantities of one dimenſion, the meaſure muſt be a line; in the ſecond, a ſuperficies; and in the third, a ſolid. For a line, *v. gr.* cannot meaſure a ſurface; to meaſure, being no more than to apply the known quantity to the unknown, till the two become equal. Now a ſurface has breadth, and a line has none: and if one line have no breadth, two or a hundred have none. A line, therefore, can never be applied ſo often to a ſurface, as to be equal to it, *i. e.* to meaſure it. And from the like reaſoning it is evident, a ſuperficies, which has no depth, cannot become equal to, *i. e.* cannot meaſure, a ſolid, which has.

While a line continues ſuch, it may be meaſured by any part of itſelf: but when the line begins to flow, and to generate a new dimenſion, the meaſure muſt keep pace, and flow too; *i. e.* as the one commences ſuperficies, the other muſt do ſo too. Thus we come to have *ſquare* meaſures, and *cubic* meaſures.

Hence we ſee why the *meaſure of a circle* is an arc, or part of the circle; for a right line can only touch a circle in one point, but the periphery of a circle conſiſts of infinite points. The right line, therefore, to meaſure the circle, muſt be applied infinite times, which is impoſſible. Again, the right line only touches the circle in a mathematical point; which has no parts or dimenſions, and has conſequently no magnitude; but a thing that has no magnitude or dimenſions, bears no proportion to another, that has; and cannot therefore meaſure it. Hence we ſee the reaſon of the diviſion of circles into 360 parts or arcs, called *degrees*. See Arc, Circle, and Degree. See alſo Mensuration.

Measuring *of Triangles*, or from three given ſides or angles to determine all the reſt, is called *trigonometry*.

Measuring *of the Air*, its preſſure, ſpring, &c. is called *aerometry*, or *pneumatics*.

MEAT, Cibus. See Food and Diet.

Meats, *Dreſſing of.* See Dressing.

Meats, *Dry.* See Xerophagy.

Meats, *White.* See White.

MEATH, in *Geography*, a county of Ireland, which, though only the tenth in ſize, is one of the moſt diſtinguiſhed on account of its many natural advantages. It is bounded on the north by the counties of Cavan, Monaghan, and Louth; on the eaſt by the Iriſh channel and port of Dublin; on the ſouth by the county of Kildare, and on the weſt by Weſtmeath. It extends from N. to S. 29 miles (36 Engliſh), and from E. to W. 35 (44½ Engliſh) miles, including an area of 512 ſquare miles, or 327,900 acres Iriſh meaſure, which are equal to 822 ſquare miles, or 526,700 acres Engliſh meaſure. This county, united with Longford, Weſtmeath, and part of ſome adjoining counties, was formerly one of the five kingdoms into which Ireland was divided; and long after the Engliſh obtained poſſeſſion of the country, it was conſidered as a diſtinct province, though it is now part of Leinſter. It derived its name, according to ſome, from a corruption of Media, from its being ſurrounded by the other kingdoms, but others derive its name from the Iriſh Magh or Maith, which ſignifies a plain or level country. On the eſtabliſhment of the Engliſh in Ireland, Henry II. made a grant of Meath to Hugh de Lacy, who planted ſeveral colonies, and erected many caſtles, and was more powerful in Ireland, as he boaſted, than Henry himſelf. In 1234 the inheritance of Meath paſſed, by marriage, to Jeffery de Geneville, from whom it, in like manner, paſſed to Mortimer, earl of March, whoſe daughter and heir married the duke of York, father of Edward IV. Meath formed a principal part of what was called the Engliſh Pale, and from the number of pariſhes into which it was divided, and the many ruins it contains, it is probable that it was then very populous. In 1792, the 147 pariſhes were, by unions, reduced to 59 benefices, of which 44 had churches, and 19 only glebe houſes. The population was eſtimated by Dr. Beaufort at 112,400, the number of houſes amounting to 22,468. Since the time that calculation was made (1792) a very great increaſe has probably taken place, but the writer knows of no *data* from which it can be eſtimated. The country

country is, in general, level, having few hills, and thofe of inconfiderable height. The foil is variable, but that moft generally met with is a ftrong deep clay upon limeftone gravel, at a greater or lefs diftance from the furface, in different places. That land which borders on the county of Louth, north of the river Boyne, is the worft and moft unprofitable, whilft the north-weftern and fouth-eaftern diftricts are the moft productive. Though fome peculiar diftricts in other counties are richer, yet there is no tract of equal extent in Ireland of fuch excellent quality, and fo appropriate to every purpofe of grazing and tillage. Meath is indeed proverbial for cattle, and not only fupplies the Dublin market, but alfo buyers from the north of Ireland, and from different parts of England. There is alfo a number of dairy farms, efpecially in the fouth-eaftern part, which fend their produce to the metropolis. Some butter is alfo made for exportation, but it is not highly prized. At Slaine there is a manufactory of cheefe carried on by natives of England. The paftures yield a luxuriant crop of natural graffes, and there is little attention paid to the introduction of others. Some marfhes on the Moynalty river feed an immenfe number of horfes in the fummer feafon; and the Kilcrew hills in the weftern angle adjoining Cavan, are remarkable for fattening fheep. Agriculture has of late years extended much, and about one-third of the county is at prefent under tillage. The crops commonly cultivated are, wheat, oats, barley, rye, clover, flax and potatoes. Cabbages, turnips, rape, and peas are alfo frequently met with, though not very general. The quantity of wafte land, exclufive of bog, is very fmall, and chiefly confifts of the commons belonging to fome of the towns, which will probably be foon enclofed.

The manufactures of this county are few. The principal is that of facking, which is made from tow, brought out of the northern counties. This manufacture is chiefly carried on in the neighbourhood of Navan. Dowlas and three-quarters wide coarfe linens are made in the parts near Drogheda, which are exported thence to the Weft Indies to clothe the negroes. In the north-weftern parts linen of a finer texture is made, which is fold in the county of Cavan. In the fouthern parts fpinning is generally neglected, and there is no manufacture except of fome coarfe frieze for home confumption. It may be added that the manufacture of ftraw hats, both of fplit and whole ftraw, has been brought to great perfection, and is carried on to a great extent. In the weftern and northern parts of the county are fome confiderable bogs, which fupply a large quantity of fuel, though not equal to the wants of the inhabitants; whilft the eaftern parts have coal from Dublin or Drogheda. There are fuppofed indications of coal in feveral parts of the county, but no mine is worked. The other mineral productions are of little importance. There is a copper mine at Skreen, from which the proprietor has yet derived no benefit; and a valuable potters' clay near Dunfhaughlin, reckoned equal, if not fuperior (fays Mr. Thompfon) to moft of the potters' clay found in Staffordfhire, which, though within fifteen miles of Dublin, has been turned to no account. Marle is found at fome depth under the bogs, fimilar to that found in Louth, which is ufeful in agriculture; and the limeftone at Ardbraccan has been thought ornamental in building.

Meath is well watered, and the attention paid to inland navigation cannot fail of contributing to its rapid improvement. The principal river is the Boyne, which rifing in the county of Kildare, enters Meath in the fouth-weftern angle, and divides it into two nearly equal parts. Its courfe lies through fome of the moft fertile and beft improved parts of the county. Its banks in moft parts rife to a confiderable height, gradually floping from the water's edge to their verdant brow, and in others bold projecting rocks and fteep precipices overhang its limpid furface. Though in fome places the river is much difturbed in its courfe by fharps and rocks, yet in others it fteals filently along through flats of confiderable extent, adding elegance and beauty to fcenes fcarcely to be equalled in Ireland. On this river, in its courfe within the county, are fix extenfive bolting mills, befides feveral grift and cloth mills, and one for the manufacture of cotton. A canal has been made, called the Boyne navigation, which is for the moft part contiguous to the river. This canal has been completed as far as Navan, but the other projected cuts to Trim, Athboy, and Kells, remain unfinifhed, which appears, from Mr. Wakefield's account, to be the cafe with moft of fuch undertakings in Ireland. The Blackwater, flowing from lough Ramor in the county of Cavan, enters the county in the north-weft, and paffing near the town of Kells, joins the Boyne at Navan. The Moynalty flows into the Blackwater, and the Athboy, Knightfbrook, and fome other fmall rivers, add their waters to the Boyne. The river Nanny, or, as it is ufually called, the *Nanny water*, rifes near Navan, and takes nearly an eafterly direction to the Irifh fea. The water of this river has, like the Bann, the character of being peculiarly adapted to the purpofes of bleaching. The fea-coaft is principally a fhelving ftrand with fhallow water, fo that little advantage is derived from it. The land adjoining is a light foil, refembling fea fand, without much vegetative power, and well adapted for rabbits. The towns in Meath are numerous, but generally fmall and ill built. Trim is the county town, but Navan is more thriving, from its eafy communication with Drogheda. Tarah hill, on which there is now an infignificant village, is faid to have been formerly the royal refidence, not only of the kings of Meath, but alfo of the monarchs of Ireland. A Danifh invader is fuppofed to have alfo taken up his abode there, and to have built the fine Danifh fort or rath on the fouth-eaft fide of the hill, which is now beautifully planted. Thompfon's Statiftical Survey of Meath. Wakefield's Account of Ireland.

Meath, a bifhopric in Ireland, the bifhop of which takes precedence of all other Irifh ones. Several fmall bifhoprics gradually coalefced into one fee, which received the name of Meath at the end of the 12th century, being the only one not taking its name from a city or town. In 1568 the bifhopric of Clonmacnoife was incorporated with it by act of parliament. It extends from the fea to the Shannon, over part of fix counties, and contains 663,600 Irifh acres. The parifhes are 224, but unlefs late improvements have been made, the churches are little more than a third part of the number. There is no cathedral in this diocefe; neither is there a chapter, nor even a dean of Meath; the only dignities are the deanery of Clonmacnoife and the archdeaconry of Meath. The revenue of this fee is ftated by Mr. Wakefield to be 6000*l. per annum*. The epifcopal refidence is at Ardbraccan, near Navan. Dr. Beaufort's Memoir of a Map of Ireland.

MEATUS, in *Anatomy*, a term applied to two paffages belonging to the ear. The meatus auditorius externus is the tube leading from the external ear to the membrana tympani. The meatus auditorius internus is the opening in the petrous portion of the temporal bone receiving the nerves of the feventh pair. See Cranium and Ear.

Meatus *Auditorius*, *Imperforate*, in *Surgery*. Obftruction of the external tube of the ear is fometimes a congenital malformation. In particular cafes, the outer opening

ing of the paſſage is cloſed by a membranous ſubſtance; in others, the canal is entirely obliterated, either by the approximation of its cartilaginous and bony parietes to each other, or by being filled up with a fleſhy maſs. In all theſe caſes of ſimple cloſure, or complete obliteration, the deafneſs, that is unavoidably produced, is not equally eaſy of cure. When the opening of the meatus auditorius externus is merely ſhut up by membrane, this may have a crucial inciſion made into it, or it may be removed altogether by cutting in a circular manner. After either of theſe operations, the new opening muſt be kept from becoming again impervious, by the introduction of tents, until the part is entirely healed. When the membrane is more deeply ſituated, the operation is leſs eaſy of accompliſhment. In this ſort of caſe Richerand adviſes us to draw the external ear upwards, in order to efface the natural curvature of the meatus, and let the entrance of the light make the ſtate of the inſide of the paſſage viſible. We are then to introduce a narrow ſtraight biſtoury, the blade of which is wrapped round with lint nearly to the point, and make an inciſion with great caution, taking particular care to avoid injuring the membrane of the tympanum. It was the apprehenſion of doing miſchief to the latter part, that induced Leſchevin to prefer, in ſuch examples, the application of cauſtic, to the employment of a cutting inſtrument. (Prix de l'Acad. de Chirurg. tom. i. p. 67. 118. 4to.) He adviſes us to apply the cauſtic to the bottom of the meatus auditorius ſeveral times, ſo as to deſtroy the preternatural membrane. It appears to us, however, that the uſe of cauſtic muſt here be exceedingly inconvenient, and hardly ſo ſafe as a biſtoury. Perhaps cauſtic may be attended with the advantage of making an opening, that will be leſs likely to cloſe again. Experience can alone determine ſuch points.

When the bony and cartilaginous parietes of the meatus auditorius are in contact, the obliteration of the paſſage is incurable. But when the canal is filled up with a fleſhy ſubſtance, the diſeaſe ſometimes admits of relief. In ſuch a caſe, M. Leſchevin recommends us to introduce a trocar, in the natural direction of the meatus auditorius, to the depth of from 15 to 18 lines. Should the point of the trocar now meet with no reſiſtance, the inſtrument muſt be withdrawn, and a tent paſſed into the artificial opening, in order to keep it from becoming cloſed. When the trocar, after being introduced to ſuch a depth, that there is reaſon to believe it has reached the natural ſituation of the cavity of the tympanum, and yet the ſame reſiſtance to its further introduction is experienced, we are recommended to abandon the operation. Were any one, ſays M. Leſchevin, here to aſcribe the want of ſucceſs to unſkilfulneſs in the ſurgeon, he would be very unjuſt.

A preternatural narrowneſs of the meatus auditorius externus is not ſo bad a caſe as its obliteration, and the deafneſs produced by it is incomplete. But it is not to be imagined, that a cure is practicable when the bony portion of this tube is the ſeat of the contraction. Should the cartilage alone be concerned, a gradual dilatation may be accompliſhed by means of prepared ſponge, or tents made of lint, the ſize of which is to be increaſed every day. Richerand acquaints us, that he has preſerved ſeveral temporal bones which belonged to ſubjects who were very hard of hearing; and in all of them the bony portion of the meatus anditorius is remarkably narrow. M. Lametrie has recorded an inſtance, in which this paſſage was ſo narrow in a young perſon, that it would ſcarcely admit of the introduction of a needle into it. Noſog. Chir. tom. ii. p. 124.—126. edit. ii.

There was a curious caſe (which was ſeen a few years ago by many medical gentlemen in London), of a total deficiency of the external ears, unattended with any meatus auditorius, the ſituation of this opening, on each ſide of the head, preſenting only the common integuments. It was remarkable, that notwithſtanding ſuch malformation, the faculty of hearing was far from being altogether deſtroyed. In all probability, the internal and moſt eſſential parts of the ear were, in this example, altogether perfect; and it ſeems not unlikely, that, by removing a portion of the ſkin over the orifice of each meatus auditorius, the hearing might have been rendered ſtill leſs dull.

Meatus Auditorius Externus, Extraneous Subſtances in.—Beſides the defects of which we have been ſpeaking, and which are, for the moſt part, congenital, the meatus auditorius may be obſtructed by foreign bodies. With reſpect to water and other liquids, they readily eſcape on putting the head in a favourable poſition. Small ſolid ſubſtances, like a pea, bean, &c. are uſually extracted with a pair of forceps, the blades of which ſhould be of a ſlender conſtruction. But if the foreign bodies cannot be thus extracted, ſurgical authors recommend us to try to break them to pieces with a ſtronger pair of forceps, in order to facilitate their removal. They alſo adviſe us to inſtil into the ear a few drops of the oil of almonds, both before and after the operation. The lodgment of extraneous ſubſtances in the ear may give riſe to a train of moſt unaccountable and perplexing ſymptoms, as may be ſeen by referring to the fourth obſervation of Fabricius Hildanus, cent. 13.

Meatus Auditorius Externus, obſtructed with Cerumen. See Deafness.

Meatus Auditorius Externus, Polypi and other Tumours of.—Theſe, when their ſituation will permit, muſt be removed with a knife, and the part to which they were attached may be touched with the argentum nitratum. When they cannot be cut away, they ſometimes admit of extraction, or of being tied in the manner of other excreſcences, ſituated in cavities. (See Polypus.) The application of cauſtic to them can ſcarcely ever be a prudent mode of treatment.

Meatus Auditorius Externus, containing Inſects.—Worms which make their appearance in the meatus auditorius are always produced ſubſequently to ulcerations in the paſſage, or in the interior of the tympanum, and, very often, ſuch inſects are quite unſuſpected cauſes of particular ſymptoms. In the caſes of ſurgery, publiſhed in 1778 at Stockholm, by Olaus Acrel, there is an inſtance confirming the ſtatement juſt offered. It is the caſe of a woman, who, having been long afflicted with a hardneſs of hearing, was ſuddenly ſeized with very violent convulſions, without any apparent cauſe, and ſoon afterwards complained of an acute pain in the ear. This affection was followed by a recurrence of convulſions, which were more vehement than before. A ſmall tent of fine linen, moiſtened with a mixture of oil and laudanum, was introduced into the meatus auditorius, and on removing it the next day, ſeveral ſmall round worms were obſerved upon it, and from that period all the ſymptoms diſappeared. To this caſe we ſhall add another from Morgagni. A young woman conſulted Valſalva, and told him, that when ſhe was a girl a worm had been diſcharged from her left ear; that another one, about ſix months ago, had alſo been diſcharged, very much like a ſmall ſilk-worm in ſhape. This event took place after ſome very acute pain in the ſame ear, the forehead, and temples. She added, that ſince this ſhe had been tormented with the ſame pains at different intervals, and ſo ſeverely, that ſhe often ſwooned away for two hours together. On recovering from this ſtate,

ſtate, a ſmall worm was diſcharged of the ſame ſhape as, but much ſmaller than, the preceding one, and that ſhe was now afflicted with deafneſs and inſenſibility on the ſame ſide. After hearing this relation, Valſalva no longer entertained any doubt of the membrane of the tympanum being ulcerated. He propoſed the employment of an injection, in order to deſtroy the neſt of worms, which he preſumed to exiſt. For this purpoſe diſtilled water of St. John's wort, in which mercury had been agitated, was uſed. Morgagni adds, that nothing appears to him more proper in ſuch caſes, to prevent a recurrence of ſuch worms, than to avoid going to ſleep, particularly in autumn and ſummer, without taking care to ſtop up the affected ear. If this be not done, flies, attracted by the ſuppuration, enter the meatus auditorius, and, while the patient is unconſcious, depoſit their eggs in the ear. Acrel, in ſpeaking of worms generated in the meatus auditorius, obſerves, that there is no better remedy for them, than the decoction of ledum paluſtre, injected into the ear ſeveral times a day. However, as it is not always poſſible to procure this plant, we ſhall recommend in ſuch caſes, in preference to all other remedies, a ſlight infuſion of tobacco in oil of almonds, a few drops of which are to be dropped into the ear, and to be retained there by means of a little bit of cotton. This application, which is not injurious to the lining of the paſſage, is fatal to inſects, and eſpecially to worms, as various experiments have convinced naturaliſts. This method may alſo ſucceed in caſes, in which caterpillars, ants, and other inſects, have inſinuated themſelves into the meatus auditorius; but it is always better, firſt to endeavour to extract them. A piece of lint, ſmeared with honey, often ſuffices for this purpoſe; and when they cannot be extracted by this ſimple means, they may be taken out with a very ſmall pair of forceps, however little of them may be viſible.

Meatus Auditorius Externus, Purulent Diſcharges from.—The ſecreted matter may either proceed from ſuppuration of this paſſage itſelf, or from diſeaſe in the tympanum, the membrane of which is imperfect. The latter caſe may be the conſequence of blows on the head, abſceſſes after fevers, the ſmall-pox, or the venereal diſeaſe. In moſt inſtances, the little bones of the internal ear are detached, and eſcape externally, complete deafneſs generally enſuing. A total loſs of hearing, however, does not invariably follow this kind of miſchief, as we have ourſelves witneſſed in one or two examples. Greater hopes of ſuch an event being avoidable may be indulged, when the diſorder is confined to the meatus; as judicious treatment may now avert the moſt ſerious conſequences. In Acrel's ſurgical caſes, there is a caſe relative to the circumſtance of which we are ſpeaking. Suppuration took place in the meatus auditorius externus in conſequence of acute rheumatiſm, which was followed by vertigo, reſtleſſneſs, and a violent head-ache. The matter diſcharged was yellowiſh, of an aqueous conſiſtence, and acid ſmell. The meatus auditorius was filled with a ſpongy fleſh. On introducing the probe, our author felt a piece of looſe rough bone, which he immediately took hold of with a pair of forceps, and extracted. From the time, when this was accompliſhed, the diſcharge diminiſhed, and, with the aid of proper treatment, the patient became perfectly well.

Meatus Auditorius Externus, Inflammation of.—This paſſage, like every other part of the body, is ſubject to inflammation, which is frequently brought on by expoſure to cold. It is hardly neceſſary to ſay, that topical bleeding and antiphlogiſtic means in general are indicated. The meatus auditorius ſhould alſo be protected from the cold air, particularly in the winter ſeaſon, by means of a piece of cotton.

Mr. Saunders obſerves, "When the means employed to reduce the inflammation have not ſucceeded, and matter has formed, it is generally evacuated; as far as I have obſerved, between the auricle and maſtoid proceſs, or into the meatus. If it has been evacuated into the meatus, the opening is moſt commonly ſmall, and the ſpongy granulations, ſqueezed through a ſmall aperture, aſſume the appearance of a polypus. Sometimes the ſmall aperture, by which the matter is evacuated, is in this manner even cloſed, and the patient ſuffers the inconvenience of frequent returns of pain from the retention of the diſcharge. When the parts have fallen into this ſtate, it will be expedient to haſten the cure by making an inciſion into the ſinus, between the auricle and maſtoid proceſs.

"It occaſionally happens, that the bone itſelf dies, in conſequence of the ſinus being neglected, or the original extent of the ſuppuration. The exfoliating parts are the meatus externus of the os temporis or the external lamina of the maſtoid proceſs." See Saunders on the Anatomy of the Human Ear and its Diſeaſes, p. 24, 25.

Meatus Auditorius, Herpetic Diſeaſe of. See Deafness.

MEAVAUA, in *Geography*, a town of Italy, in the county of Bormio; five miles N.E. of Bormio.

MEAUDEE, a town of the Birman empire, on the left bank of the Ava; 10 miles N. of Prome.

MEAUX, a town of France, principal place of a diſtrict, in the department of the Seine and Marne, before the revolution the ſee of a biſhop, and diſtinguiſhed by having been the firſt ſcene of the reformation in the time of Francis. The chief traffic conſiſts in grain, wool, and cheeſe. The city contains 6447, and the canton 14,484 inhabitants, on a territory of 127 kiliometres, in 15 communes. N. lat. 48° 58′. E. long. 2° 57′.

MEBOREA, in *Botany*, a word of whoſe origin no account is given, Aubl. Guian. 826. t. 323. (See Rhopium.) Juſſieu places this genus amongſt his *Plantæ incertæ ſedis*. We ſhould have ſuppoſed it one of his *Euphorbiæ*, though it may not anſwer to all the characters he has given of that order.

MEBU, in *Geography*, a town of Japan, in the iſland of Niphon; 160 miles N.W. of Jedo.

MECATINA, an iſland in the gulf of St. Lawrence. N. lat. 50° 48′. W. long. 59° 10′.

MECCA, a city of Arabia, known to the Greeks under the name of "Macoraba," is ſituated in a dry and barren tract of country, a full day's journey from *Jidda*, which ſee. "Some latent motives perhaps of ſuperſtition," ſays Gibbon (Decl. Rom. Emp. vol. ix. p. 223.) "muſt have impelled the founders of this city to the choice of a moſt unpromiſing ſituation. Their habitations were erected of mud or ſtone, in a plain about two miles long and one broad, at the foot of three barren mounatins; the ſoil being a rock; the water even of the holy well of Zemzem being bitter or brackiſh; the paſtures remote from the city; and grapes tranſported to it above 70 miles from the gardens of Tayef. The fame and ſpirit of the Koreiſhites, who reigned in Mecca, were conſpicuous among the Arabian tribes; but their ungrateful ſoil refuſed the labours of agriculture, and their poſition was favourable to the enterprizes of trade. By the ſea-port of Gedda (or Jidda), at the diſtance only of 40 miles, they maintained an eaſy correſpondence with Abyſſinia; and the Chriſtian kingdom afforded the firſt refuge to the diſciples of Mahomet. The treaſures

treasures of Africa were conveyed over the peninsula to Gerrha or Katif, in the province of Bahrein, a city built, as it is said of rock salt, by the Chaldean exiles; and from thence, with the native pearls of the Persian gulf, they were floated in rafts to the mouth of the Euphrates. Mecca is placed almost at an equal distance, a month's journey, between Yemen on the right, and Syria on the left hand. The former was the winter, and the latter the summer station of her caravans: and their seasonable arrival relieved the ships of India from the tedious and troublesome navigation of the Red sea. In the markets of Saana and Merab, in the harbour of Oman and Aden, the camels of the Koreishites were laden with a precious cargo of aromatics; a supply of corn and manufactures was purchased in the fairs of Bostra and Damascus; the lucrative exchange diffused plenty and riches in the streets of Mecca; and the noblest of her sons united the love of arms with the profession of merchandize." On an approach to the high lands, a few leagues beyond it, abundance of excellent fruits is to be found. In the summer months, the heat is excessive at Mecca, and in order to avoid and moderate it as much as possible, the inhabitants take care to shut their windows and water the streets. Instances have occurred, of persons that have been suffocated in the streets by the burning wind, called "Samoum," or "Samiel." As many of the first nobility in Hedjas reside at Mecca, the buildings are better here than in any other city in Arabia. Among its elegant edifices the most remarkable is the Kaba or Caaba, or house of God, which was held in high veneration by the Arabians, even before the days of Mahomet. (See CAABA.) Niebuhr says, that no Christian dares to enter Mecca, on account of the prejudices of the people with respect to the sanctity of the place, who think that it would be profaned by the feet of infidel Christians; though there is no prohibition to this purpose in the laws of Mahomet. The superstitious people persuade themselves, that Christians are restrained from approaching it by a supernatural power. We may hence presume, that the Christians of Europe, who describe Mecca as eye-witnesses, have been renegadoes, who have escaped from Turkey. The Mahometans have such high ideas of the sanctity of Mecca, that they suppose it to extend even to the environs of the city. Its territory is reputed sacred, to a certain distance round it, which is indicated by marks set up for this purpose. Every caravan finds one of these marks in their way, which warns the pilgrims to put on the modest garb which it becomes them to wear on that sacred ground. The government of this holy city is seated in a Sherriff, who is a temporal prince; and his revenue is increased by the donations of Mahometan sovereigns. N. lat. 21° 47′. E. long. 56° 46′.

Every Mussulman, it is well known, is obliged, once in his life, to visit Mecca, and to perform acts of devotion in the sacred places. But if this duty were universally performed, the concourse of pilgrims would be immense, and the city would not contain the crowds that would resort to it from every country in which the Mahometan religion has been introduced. Those, whose circumstances do not admit of their undertaking this pilgrimage, are allowed to have a person to perform it for them. But a pilgrim of this description can act for no more than one person at the same time; and, in order to prevent imposture, he must bring back a formal attestation from an Imam at Mecca, testifying, that he has actually performed the appointed devotional exercises in the holy places, in the name of such a person, living or dead; for even after the death of any person, who, during life, has neglected this duty, it may be discharged in his name, and for his benefit. The caravans that visit this city, are frequently composed of persons who become pilgrims more from motives of interest and traffic than from those of devotion. (See CARAVAN.) A pilgrim who has not been present from the commencement at the celebration of all the ceremonies, and performed every act of devotion, cannot obtain the title of "Hadgi;" an honour much courted by the Turks, because it confers substantial privileges, and commands respect to those who bear it. (See MAHOMET and MAHOMETANISM.) We shall here observe, that a similar custom prevails among the Christians in the East, who are very anxious to obtain the title of "Hadgi" or "Mokdasi," which they give to pilgrims of their communion. In order to acquire this title, it is not sufficient for a person to go in pilgrimage to Jerusalem: he must spend the season of the passover in that city, and assist at all the ceremonies in the holy weeks. See PILGRIM.

MECCA, a town of Morocco, near the coast of the Atlantic. S. lat. 29° 45′. W. long. 9° 45′.

MECHADER, a town of Arabia, in Yemen; 27 miles S. of Sana. N. lat. 14° 7′. E. long. 44° 15′.

MECHAIN, PETER FRANCIS ANDREW, in *Biography*, a very able French mathematician and astronomer, was born at Laon in the year 1744. At an early age he discovered a strong inclination for mathematical pursuits, and while he was under the instruction of his tutors, corresponded with Lalande, whom he was desirous of assisting in his labours. In 1772, Mechain was invited to Paris, where he was employed at the depôt of the marine, and assisted M. Darquier in correcting his observations. Here his merit brought him acquainted with M. Doisy, director of the depôt, who gave him a more advantageous situation at Versailles. At this place he diligently observed the heavens, and, in 1774, sent to the Royal Academy of Sciences, "A Memoir relative to an Eclipse of Aldebaran," observed by him on the 15th of April. He calculated the orbit of the comet of 1774; and discovered that of 1781. In 1782, he gained the prize of the academy on the subject of the comet of 1661, the return of which was eagerly expected in 1790; and in the same year he was admitted a member of the academy, and soon selected for the superintendance of the Connoissance des Tems. In the year 1790, M. Mechain discovered his eighth comet, and communicated to the academy his observations on it, together with his calculations of its orbit. In 1792 he undertook, conjointly with M. Delambre, the labour of measuring the degrees of the meridian, for the purpose of more accurately determining the magnitude of the earth and the length of a metre. In the month of June 1792, M. Mechain set out to measure the triangles between Perpignan and Barcelona; and notwithstanding that the war occasioned a temporary suspension of his labours, he was enabled to resume and complete them during the following year. He died on the 20th of September 1805, at Castellon de la Plana, in the sixty-second year of his age. Lalande deplores his loss as that of not only one of the best French astronomers, but one of the most laborious, the most courageous, and the most robust. His last observations and calculations of the eclipse of the sun on the 11th of February, are inserted in the Connoissance des Tems for the year 15, and he also published a great many in the Ephemerides of M. Bode of Berlin, which he preferred to a former work after Lalande became its editor. A more extensive memoir of his labours may be seen in baron von Zach's Journal for July 1800; and Lalande's History of Astronomy for 1804.

MECHANICS, that branch of practical mathematics which

which confiders motion and moving powers, their nature, laws, effects, &c. This term, in a popular fenfe, is applied equally to the doctrine of the equilibrium of powers, more properly called ftatics, and to that fcience which treats of the generation and communication of motion, which conftitutes dynamics, or mechanics ftrictly fo called. See STATICS, POWER, MOTION, and DYNAMICS.

This fcience is divided by Newton into practical and rational mechanics, the former of which relates to the mechanical powers, *viz.* the lever, balance, wheel and axis, pulley, wedge, fcrew, and inclined plane; and the latter, or rational mechanics, to the theory of motion; fhewing, when the forces or powers are given, how to determine the motion that will refult from them, and converfely when the circumftances of the motion are given, how to trace the forces or powers from which they arife.

Mechanics, according to the ancient fenfe of the word, confiders only the energy of *organa*, or machines. The authors who have treated the fubject of mechanics fyftematically have obferved, that all machines derive their efficacy from a few fimple forms and difpofitions, that may be given to the *organa*, which are interpofed between the agent and the refiftance to be overcome; and to thofe fimple forms they have given the name of mechanical powers, fimple powers, or fimple machines. See MECHANICAL *Powers*.

The practical ufes of the feveral mechanical powers were undoubtedly known to the ancients, but they were almoft wholly unacquainted with the theoretical principles of this fcience till a very late period; and it is therefore not a little furprifing that the conftruction of machines, or the inftruments of mechanics, fhould have been purfued with fuch induftry, and carried by them to fuch perfection. Vitruvius, in his 10th book, enumerates feveral ingenious machines which had then been in ufe from time immemorial. We find, that for raifing or tranfporting heavy bodies, they employed moft of the means which are at prefent commonly ufed for that purpofe, fuch as the crane, the inclined plane, the pulley, &c.: but with the theory or true principles of equilibrium they feem to have been unacquainted till the time of Archimedes. This celebrated mathematician, in his book of Equiponderants, confiders a balance fupported on a fulcrum, and having a weight in each fcale; and taking as a fundamental principle, that when the two arms of the balance are equal, the two weights fuppofed to be in equilibrio are alfo of neceffity equal, he fhews, that if one of the arms be increafed, the weight applied to it muft be proportionally diminifhed. Hence he deduces the general conclufion, that two weights fufpended to the arms of a balance of unequal length, and remaining in equilibrio, muft be reciprocally proportional to the arms of the balance; and this is the firft trace any where to be met with of any theoretical inveftigation of mechanical fcience. Archimedes alfo farther obferved, that the two weights exert the fame preffure on the fulcrum of the balance, as if they were directly applied to it; and he afterwards extended the fame idea to two other weights fufpended from other points of the balance, then to two others, and fo on, and hence, ftep by ftep, advanced towards the general idea of the centre of gravity, a point which he proved to belong to every affemblage of fmall bodies, and confequently to every large body, which might be confidered as formed of fuch an affemblage. This theory he applied to particular cafes, and determined the fituation of the centre of gravity in the parallelogram, triangle, trapezium, parabola, parabolic trapezium, &c. &c. To him we are alfo indebted for the theory of the inclined plane, the pulley, and the fcrew, befides the invention of a multitude of compound machines, of which, however, he has left us no defcription, and therefore little more than their names remain.

We may judge of the very imperfect ftate in which the theory of mechanics was at that time, by the aftonifhment expreffed by king Hiero, when Archimedes exclaimed, "Give me a place to ftand on and I will move the earth," a propofition which could have excited no furprife in any perfon poffeffing a knowledge of the fimple property of the lever. Of the theory of motion, however, it does not appear that even Archimedes poffeffed any adequate idea; the properties of uniform motion feem only to have engaged the attention of the ancients, and with thofe of accelerated and variable motion they were totally unacquainted: thefe were fubjects to which their geometry could not be applied, the modern analyfis being neceffary to bring this branch of the fcience to perfection.

From the time of Archimedes till the commencement of the fixteenth century, the theory of mechanics appears to have remained in the fame ftate in which it was left by this prince of Grecian fcience, little or no additions having been made to it during fo many ages; but about this time, Stevinus, a Flemifh mathematician, made known directly, without the introduction of the lever, the laws of equilibrium of a body placed on an inclined plane: he alfo inveftigated, with the fame fuccefs, many other queftions on ftatics, and determined the conditions of equilibrium between feveral forces concurring in a common point, which comes, in fact, to the famous propofition relating to the parallelogram of forces; but it does not appear, however, that he was at all aware of its confequences and application. In 1592, Galileo compofed a treatife on Statics, which he reduced to this fingle principle, *viz.* it requires an equal power to raife two different bodies to heights having the inverfe ratio of their weights; that is, whatever power will raife a body of two pounds to the height of one foot, will raife a body of one pound to the height of two feet. On this fimple principle he inveftigated the theory of the inclined plane, the fcrew, and all the mechanical powers, and Defcartes afterwards employed it in confidering the ftatical equilibriums of machines in general, but without quoting Galileo, to whom he had been indebted for the firft idea. To Galileo we are alfo indebted for the theory of accelerated motion, and its complete coincidence with the obferved phenomena of nature may be confidered as one of the greateft fteps made at one time in the fcience of phyfics. Since all bodies, faid this philofopher, are heavy, into whatever number of parts we divide any mafs, it follows, that its total weight is proportional to the number of material atoms of which it is compofed. Now the weight being thus a power always uniform in quantity, and its action never undergoing any interruption, it muft, in confequence, be continually giving new impulfes to a body, in every equal and fucceffive inftant of time, and while the body is falling, thefe impulfes are inceffantly accumulating, and remain in the body without alteration, the refiftance of the air alone being deducted, and hence the motion muft be accelerated by equal degrees.

Torricelli, a pupil of Galileo, profecuted the fubject after his mafter, and added feveral curious propofitions concerning projectiles, to thofe which the latter had previoufly inveftigated. Huygens confidered the motion of bodies along given curves, and demonftrated that the velocity of a heavy body, which defcends along any curve, is the fame at every inftant in the direction of the tangent, as it would have acquired by falling freely from a height equal to the correfponding vertical abfcifs. Then applying this principle to the inverted cycloid, the axis of which is vertical, he found that

that a heavy body, from whatever part of the cycloidical arc it falls, always arrives at the lowest point of that arc in the same space of time. This very remarkable proposition includes what is commonly called the *isochronism* of the cycloid, and would alone have been sufficient to establish the fame of a geometrician. In 1661, Huygens, Wallis, and sir Christopher Wren, all discovered the true laws of percussion separately, and without any communication with each other, a proposition which Descartes had previously attempted, but failed in giving it a general solution. The finding of the centres of oscillation in compound bodies soon followed that relating to percussion, and here again Huygens equally distinguished himself by the accuracy and elegance of his solution; but as the principles which he employed were not well understood by the philosophers and mathematicians of that period, his investigations were much criticised at the time; but the honour of the discovery was finally attributed to him, and those of Descartes and Roberval admitted to be erroneous, or at least not sufficiently general. However, before the discovery of the fluxional calculus, there were many curious and interesting mechanical properties which the ancient geometry was incompetent to investigate, and which could never have been brought to light but by the assistance of this modern branch of analysis.

After the foundation of statics was laid by Archimedes, it was not difficult to discover the conditions of equilibrium in every particular case, and these had guided the genius of invention in a number of machines, but they were not yet reduced to a general and uniform principle.

Varignon undertook and accomplished this plan of combining them, by means of the theory of compound motions. He gave some sketches of this in 1687, in his Project of a new System of Mechanics, and he in some degree exhausted all the combinations of the equilibrium of machines, in his "General Mechanics," not published till after his death, in 1725. In 1695, la Hire published a "Treatise on Mechanics," the general object of which, like that of Varignon's, is the equilibrium of machines, beside which it contains various applications of machines to the arts, in which the author was well versed. He also subjoined a treatise on epicycloids, and their use in this science, particularly as relating to the forms of teeth in wheel-work. This is a beautiful theory, and is highly creditable to its author, who it appears from the testimony of Leibnitz was not la Hire, though he published it as such, but was due to the celebrated Danish mathematician Roemer, who had communicated it to Leibnitz twenty years before la Hire's work appeared. After this period, several elementary treatises on the subject of mechanics were published, without, however, adding much to the previous stock of knowledge, unless indeed we except that of Cormus, a work highly valuable for the strictness and perspicuity of its demonstrations.

At this time very little had been done with regard to the theory of variable motion; this now began to engage the attention of mathematicians, and opened an extensive field to their researches. Galileo, as we have seen, made known the properties of rectilinear and uniformly accelerated motions; Huygens had treated of curvilineal motion, which finally led to the beautiful theory of central forces in a circle, and which is equally applicable to motion in any curve, by considering them as infinite series of small arcs of a circle, agreeably to the idea which he himself had employed in his general theory of evolutes. The laws of the communication of motion, likewise sketched by Descartes, and farther pursued by Wallis, Huygens, and Wren, had made a new and very considerable step, by means of the solution which Huygens gave of the celebrated problem of the centres of oscillation. All these acquisitions, at first separate and in some measure independent of each other, having been reduced to a small number of simple, commodious, and general formulæ, by means of the analysis of infinites, the science of mechanics acquired fresh vigour, and was prosecuted with the most unbounded success. The problems relating to motion were reduced into two classes; the first comprising the general problem of the motion of a single body acted upon by any given powers; and the second, the motions which result from the action and re-action that several bodies exert on each other in any given manner.

In the motion of a single body, we observe that matter, being of itself passive, if once set in motion, must uniformly persevere in it; and that its motion can neither increase nor diminish, unless by the action of some external power, which may be either constant or variable. And hence arise two principles, that of *vis inertiæ* and that of compound motion; and on these are founded the whole theory of motion, rectilineal or curvilineal, constant or variable, according to a given law. By virtue of the *vis inertiæ*, motion at every instant is essentially rectilinear and uniform, setting aside resistance and every obstacle that might otherwise impede or change its direction; and by the nature of compound motion, a body exposed to the action of a given number of forces, all tending at the same time to change the quantity and direction of its motion, takes such a path through space that in the last instant it reaches the same point at which it would have arrived, had it successively and freely obeyed each of the forces proposed.

On applying these principles to rectilineal motions uniformly accelerated, we perceive, 1st, that in this motion, the velocities increasing by equal degrees, or proportionally to the time, the accelerating force must be constant, or incessantly give equal impulses to the moving body, and that, consequently, the final velocity is as the product of the accelerating force multiplied by the time. 2dly. Each elementary portion of space passed through being as the product of the corresponding velocity multiplied by the element of the time, the whole of the space passed through is as the product of the accelerating force multiplied by the square of the time; and these two properties equally take place for each elementary portion of any variable motion whatever. Thus in every rectilineal motion variable according to a given law, the increment of the velocity is as the product of the accelerating force into the element of the time, and the second fluxion of the space passed through is as the product of the accelerating force into the square of the element of the time. Now if to these principles we add that of compound motion, we shall arrive at the knowledge of all curvilineal motion whatever. In fact, whatever forces be applied to a body describing a curve, we may at each instant reduce these forces to two, the one acting in the direction of the tangent at any point of the curve, and the other perpendicular to it; the first produces an instantaneous rectilineal motion, to which the principle of *vis inertiæ* applies; and the second is expressed by the square of the actual velocity of the body, divided by the radius of curvature, agreeably to the theory of central forces in the circle, which equally reduces to the same principle the motion in the direction of the radius of curvature. Such were the general principles introduced into the science of mechanics by means of the modern analysis, and there seems to be no doubt that it was by pursuing this theory, Newton was led to those brilliant discoveries which he afterwards published in his "Principia" under a different form. In 1716, Hermann published his "De Phoronomia," in which he undertook to explain all that regards mechanics, both of solids

solids and fluids, that is to say, statics, dynamics, hydrostatics, and hydraulics; in which he employs the synthetic method, although, like Newton, he doubtless derived most of his results from analysis, a circumstance which frequently interrupts the unity and connection of his problems.

The Mechanics of Euler, published in 1736, contain the whole theory of rectilinear and curvilinear motion in an isolated body, acted upon by any accelerating forces whatever, either in vacuo or in a resisting medium. The author has every where followed the analytical method, which, by reducing all the branches of this theory to uniformity, greatly facilitates the connection of it, and the whole is managed with an elegance and perspicuity, of which, before this time, we had no example. As to the principles of mechanics by which he puts his problems into equations, he employs those above mentioned.

This manner of laying the foundation of the calculation, however, though sufficiently commodious, was not the only one that might have been employed, nor was it the most simple. For the forces and motions at every instant may be resolved into other forces and motions parallel to fixed lines of given position in space. In which case nothing more is necessary than to apply the equations of the principles of *vis inertiæ* to these motions and forces, by which means the theorem of Huygens may be avoided. This simple idea, which was first employed by Maclaurin in his "Treatise on Fluxions," threw new light on the theory of mechanics, and much facilitated the solution of various problems. When the body moves constantly in one plane, two fixed axes only are to be taken, which are supposed to be perpendicular to each other, for the sake of greater simplicity; but when we are obliged, by the nature of the forces, to change the path continually in all directions, and to describe a curve of double curvature, three axes are to be employed perpendicular to each other, or forming the edges of a right-angled parallelopipedon. But the problems relating to the communication of motion, commonly called *dynamic problems*, required new principles. These, for instance, consist in determining the motions that result from the percussion of several bodies; the centre of oscillation of a compound pendulum; the motions of several bodies strung upon a rod, which has a rotatory movement round a fixed axis; &c.

Now it is evident, that in all cases of this kind the motion of the bodies is not the same as if the bodies were isolated and at liberty, but that there must be a distribution of the forces among all the bodies forming one whole, so that the motion gained by some of them is lost by others. The motion gained or lost is always estimated by the product of the mass into the velocity received or lost, whether the communication or the loss of motion be produced every instant by finite degrees, as in the shock of hard bodies, or whether the velocity change at each instant only by degrees infinitely small, as in motion of several bodies strung on a moveable rod, and generally in all cases where forces act in the manner of gravitation.

When Huygens gave his solution of the problems of oscillation, some unskilful mathematicians attacked it in reviews. James Bernouilli defended it in the Leipsic Transactions for 1686, and undertook to give a direct demonstration by means of the principle of the lever. At first, he considered only two equal weights fastened to an inflexible rod devoid of gravity, which was in motion round an horizontal axis. Having then observed that the velocity of the weights, nearest to the axis of rotation, must necessarily be less, and that on the other greater, than if each acted on the rod separately, he concludes that the force lost and the force gained balance each other, and that, consequently, the product of the quantity of matter in one, into the velocity it loses, and that of the other multiplied by the velocity it gains, must be inversely proportional to the arms of the lever. This reasoning is in fact accurate, only James Bernouilli mistook in setting out, by considering the velocities of the two bodies as finite, instead of which he should only have considered the elementary velocities, and compared them with the similar velocities produced every instant by the action of gravitation. De l'Hôpital remarked this error, and in correcting it, he found the centre of oscillation of the two weights, without departing in other respects from the principle of Bernouilli. In order then to proceed to a third weight, he united the former two at their centre of oscillation, and combined this new weight with the third, as he had combined together the former two, and so on. But the proposed union was a little precarious, and could not be admitted without a demonstration. This led Bernouilli to revive his former solution, in order to extend it generally to any number of bodies, which he finally accomplished. His method consists in resolving the motion of each body at any given instant into two other motions, the one, that which the body actually takes; and the other, that which is destroyed, and in forming equations which express the condition of equilibrium between the motions lost; by which means the problem is brought under the general laws of statics. The author applies this principle to several examples, and demonstrates strictly, and in the most evident manner, the proposition which Huygens employed as the basis of his solution. See Memoirs of the Academy of Sciences for 1703.

This solution of the problem of the centres of oscillation, seemed to leave nothing to be desired; yet, in 1714, it was brought forward again by John Bernouilli and Dr. Taylor, which were fundamentally the same. This occasioned warm disputes between them, as to the originality of their performances. Here, instead of the elementary weights of which the pendulum is composed, other weights are supposed to be substituted, in one and the same point, such that their motion of angular acceleration, and their motion with respect to the axis of rotation, shall be the same, and the new pendulum oscillate as the former. But these solutions are not considered so luminous as that of James Bernouilli, which was founded immediately on the laws of equilibrium. Leibnitz estimated the momenta of bodies by the mass into the square of their velocities, and John Bernouilli having adopted the same opinion, gave to the principles of Huygens, for the problem of the centres of oscillation, the name of the principle of conversion of the *vires vivæ*, which it has retained, because, in fact, in the motion of a system of heavy bodies, the sum of the products of the masses into the squares of the velocities remains the same, when the bodies descend conjointly, and when they afterwards ascend separately, with the velocities they acquired by their descent. This principle was also followed with success in dynamical problems, by several able analysts of the last century; but as it gives only a single equation, from which the velocity or the time must afterwards be expunged, the second object was attained by different means.

John Bernouilli employed for this purpose the principle of *tensions*; Euler, that of *pressures*; Daniel Bernouilli, that of *virtual power*, which a system of bodies has of re-establishing itself in its former state; and in certain cases both he and Euler made use of the constant quantity of circulatory motion round a fixed point. And when at length all the differential, or fluxional equations of the problem were

were eſtabliſhed, it remained only to reſolve them, which was of courſe the leaſt difficult part of their inveſtigations.

The principle which had been employed by James Bernouilli, in the ſolution of the problem relating to the centre of oſcillation, was generalized by D'Alembert; he ſhewed, that in whatever manner the bodies of one ſyſtem act upon each other, their motions may always be reſolved at every inſtant into two ſorts of motions, thoſe of the one being deſtroyed in the ſucceſſive inſtant, but the other retained; and that the motions retained are neceſſarily known from the conditions of the equilibrium between the motions deſtroyed. This general principle applies to all the problems of dynamics, and at leaſt reduces all their difficulties to thoſe of the problems of ſimple ſtatics; and renders uſeleſs that of the converſion of *vires vivæ*. By this means D'Alembert has reſolved a number of very beautiful and very difficult problems, ſome of which were abſolutely new, as, for example, that relating to the preceſſion of the equinoxes. Theſe general principles were firſt developed by D'Alembert in 1743, but they were more fully treated of in his Treatiſe of Dynamics, publiſhed in 1749; a truly intereſting and original work, highly creditable to the talents of this celebrated author. The ſcience of dynamics having thus gradually attained a high degree of perfection, was ſtill farther enriched, in 1765, by an important diſcovery, which is due to Segner; who has ſhewn in a ſhort paper entitled "Specimen Theoriæ Turbinum," *that if a body, of any ſize and figure, after rotatory or gyratory motions in all directions have been given to it, be left entirely to itſelf, it will always have three principal axes of rotation;* that is, that all the rotatory motions, by which it is affected, may conſtantly be reduced to three, which are performed round three axes perpendicular to each other paſſing through the centre of gravity or inertiæ of the body, and always preſerving the ſame poſition in abſolute ſpace, while the centre of gravity is at reſt, or moves uniformly in a right line; the poſition of theſe three axes being determined by an equation of the third order. This theory, which its author had not ſufficiently developed, Albert, the ſon of the celebrated Euler, treated at length in his paper "On the Stowage of Ships," which ſhared the prize of the Academy of Sciences at Paris for 1761, as did likewiſe his father, according to the ſame method, in the Memoirs of the Academy at Berlin for 1759, and in his work entitled "Theoria Motus Corporum rigidorum, 1765." Laſtly, D'Alembert ſhewed in his "Mathematica Opuſcula," vol. iv. publiſhed in 1768, that the ſolution of the problem was deducible from the formulæ which he had given in a memoir for determining the motion of a body of any figure, acted upon by any forces whatever, printed in vol. i. of his Opuſcula in 1761. The knowledge of theſe motions of free rotation round three principal axes, naturally led to the determination of the motion round any variable axes whatever; and hence, if we conſider the body to be acted upon by any given accelerating forces, we muſt begin with determining the rectilinear or curvilinear motion of the centre of gravity abſtractedly from all rotatory motion, and then combining this progreſſive motion with the rotatory motion of a given point of the body round a variable axis, we ſhall know at every inſtant the compound motion of this point in abſolute ſpace. On theſe principles Euler has reſolved many curious and intereſting problems relating to dynamics, and the ſame have been ſince farther proved by ſubſequent mathematicians. (Boſſut's Hiſt. Math.) We have thus given a ſketch of the hiſtory and ſucceſſive improvements of the ſcience of mechanics, which is all that is neceſſary under the preſent article, as the particular branches connected with this ſubject are treated of ſeparately under their reſpective heads in the different articles of this work. But as we have only directed our attention to the more prominent parts of the hiſtory, the works to which our references have been made are very limited. It remains, therefore, before we conclude this article, to enumerate ſome of the principal writers on mechanics, or on particular branches of it, which are as follows, *viz.*

Newton, in his "Principia;" Guido Ubaldus, in his "Liber Mechanicorum;" Torricelli, "Libri de Motu Gravium naturalitis Decendentium et Projectorum;" Balianus, "Tractatus de Motu naturali Gravium;" Huygens, "Horologium Oſcillatorium," and "Tractatus de Motu Corporum ex Percuſſione;" Leibnitz, "Reſiſtentia Solidorum," in Acta Euroditus, ann. 1684; Guldinus, "De Centro Gravitatis;" Wallis, "Tractatus de Mechanica;" Varignon, "Projet d'une Nouvelle Mechanique," and his papers in the Memoires Acad. ann. 1702; Borelli, "Tractatus de Vi Percuſſionis, de Motionibus naturalibus, &c.;" De Chales, "Treatiſe on Motion;" Pardies, "Diſcourſe on Local Motion;" Parent, "Elements of Mechanics and Phyſics;" Caſatus, "Mechanica;" Oughtred, "Mechanical Inſtitution;" Robault, "Tractatus de Mechanica;" Lamy, "Mechanique;" Keil, "Introduction to true Philoſophy;" De la Hire, "Mechanique;" Mariotte, "Tracti du Choc du Corps;" Ditton, "Laws of Motion;" Hermann, "Phoronomia;" Graveſande, "Phyſics;" Euler, "Tractatus de Motu;" Muſchenbroeck, "Phyſics;" Boſſu, "Mechaniques;" La Grange, "Mechanique Analytique;" Atwood, "On Motion;" Prony, "Architeture Hydraulique," and "Mechanique Analytique;" Francear, "Mechanique;" Gregory, "Mechanics in Theory and Practice," &c. &c. to which may be added the names of Nicholſon, Enfield, Wood, Ferguſon, Young, and Marat. For thoſe works which relate principally to the deſcription of machinery, ſee the article MACHINE.

MECHANICAL, ſomething that relates to mechanics, or is regulated by the nature and laws of motion.

In which ſenſe we ſay mechanical powers, mechanical properties or affections, mechanical principles, reaſoning, knowledge, &c.

MECHANICAL *Affections*, are ſuch properties in matter, as reſult from their figure, bulk, and motion.

MECHANICAL *Cauſes*, are thoſe founded on ſuch affections.

MECHANICAL *Force*. See FORCE.

MECHANICAL *Solutions*, are accounts of things on the ſame principles.

MECHANICAL *Philoſophy*, is the ſame with what we otherwiſe call the *corpuſcular philoſophy; viz.* that which explains the phenomenon of nature, and the operations of corporeal things, on the principles of mechanics; *viz.* the motion, gravity, figure, arrangement, diſpoſition, greatneſs, or ſmallneſs of the parts which compoſe natural bodies. See CORPUSCULAR.

MECHANICAL *Powers*, (ſo called,) are thoſe machines which are uſed for raiſing greater weights, or overcoming greater reſiſtances than could be effected by the natural ſtrength without them; the power of ſtrength being applied to one part of the machine, and another part of the machine applied to the weight or reſiſtance.

There are two principal problems that ought to be reſolved in treating of each of them.

The firſt is, to determine the proportion which the power and

and weight ought to have to each other, that they may juſt ſuſtain one another, or be in equilibrio.

The ſecond is, to determine what ought to be the proportion of the power and weight to each other in a given machine, that it may produce the greateſt effect poſſible, in a given time.

As to the firſt problem, this general rule holds in all powers; ſuppoſe the engine to move, and reduce the velocities of the power and weight to the reſpective directions in which they act; find the proportions of thoſe velocities; then if the power be to the weight as the velocity of the weight is to the velocity of the power; or, which amounts to the ſame thing, if the power multiplied by its velocity, gives the ſame product as the weight multiplied by its velocity, this is the caſe wherein the power and weight ſuſtain each other, and are in equilibrio; ſo that in this caſe the one would not prevail over the other, if the engine was at reſt; and if it is in motion, it would continue to proceed uniformly, if it were not for the friction of its parts, and other reſiſtances.

The ſecond general problem in mechanics is, to determine the proportion which the power and weight ought to bear to each other, that when the power prevails, and the machine is in motion, the greateſt effect poſſible may be produced by it in a given time. It is manifeſt, that this is an enquiry of the greateſt importance, though few have treated of it. When the power is only a little greater than that which is ſufficient to ſuſtain the weight, the motion is too ſlow; and though a greater weight is raiſed in this caſe it is not ſufficient to compenſate the loſs of time. When the weight is much leſs than that which the power is able to ſuſtain, it is raiſed in leſs time; and this may happen not to be ſufficient to compenſate the loſs ariſing from the ſmallneſs of the load. It ought, therefore, to be determined when the product of the weight, multiplied by its velocity, is the greateſt poſſible; for this product meaſures the effect of the engine in a given time, which is always the greater in proportion as the weight which is raiſed is greater, and as the velocity with which it is raiſed is greater. For other conſiderations neceſſary to be regarded in the conſtruction and uſe of machines, we refer to the articles MACHINE and MACHINERY.

The ſimple machines by which power is gained, are ſix in number, *viz.* the *lever*, the *wheel and axle*, or *axis in peritrochio*, the *pulley* (or rather ſyſtem of pullies), the *inclined plane*, the *wedge*, and the *ſcrew*. Of theſe, all ſorts of mechanical engines conſiſt; and in treating of them, ſo as to ſettle their theory, we muſt conſider them as mechanically exact, and moving without friction. Although theſe machines are treated of at large under their proper heads, it may not be amiſs to give a ſhort account of them all here.

1. A *lever* is an inflexible bar, turning upon a ſupporting prop as its centre of motion, which muſt be firm enough to bear the lever and the weight with which it is charged. There are three kinds of levers, and in each of them the velocity of each point is directly as its diſtance from the prop.

A lever is ſaid to be of the firſt kind when the prop is between the weight and the power. Here the power and weight balance each other, when the power is in proportion to the weight as the diſtance of the weight from the prop is to the diſtance of the power from it; ſo that if a weight be twenty pounds, and at one foot from the prop, a power of one pound at twenty feet from the prop will balance the weight, ſuppoſing the lever itſelf to have no weight. To this ſort of lever may be reduced all iron crows, ſciſſars, pinchers, candle-ſnuffers, and the like.

A lever is ſaid to be of the ſecond kind, when the weight is between the prop and the power. Here the lever and weight balance each other when the power is in proportion to the weight as the diſtance of the weight from the prop is to the diſtance of the power from it. Of this ſort are doors turning on hinges, oars, and ſuch knives as are fixed at the point.

A lever is ſaid to be of the third kind when the power is between the weight and the prop. In this, the power and weight balance each other, when the power is in proportion to the weight, as the diſtance of the weight from the prop is to the diſtance of the power from it: but this lever is never uſed where power is wanted to be gained; for in it, the intenſity of the power applied, muſt always exceed the intenſity of the weight to be raiſed, or reſiſtance to be overcome. Of this ſort are the bones of our legs and arms, and the wheels of clocks and watches. See LEVER and BALANCE.

2. In the *wheel and axle*, where the power is applied to the wheel, and the weight drawn up by a rope winding round the axle, the velocity of the power is to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle, and the advantage gained by the machine is in the ſame proportion: for the power and weight balance each other when the power is in proportion to the weight, as the circumference of the axle is to the circumference of the wheel. This machine is the principal part of a common *crane*. See AXIS in *Peritrochio*.

3. A *pulley*, that only turns on its axis, and does not riſe with the weight, ſerves only to change the direction of the power; for it gives no mechanical advantage thereto. But when, beſides the upper pullies, which turn round in a fixed frame, or block, there is a block of pullies moving equally faſt with the weight, the velocity of the weight is to the velocity of the power as one is to twice the number of pullies in the moveable block: and the power and weight balance each other when the power is in proportion to the weight, as one is to twice the number of pullies in the moveable block. See PULLEY.

4. An *inclined plane* is like one-half of a wedge which has been cut in two equal parts lengthwiſe. A weight raiſed, or a reſiſtance moved, by an inclined plane, moves only through a ſpace equal to the height of that machine, in the time that a power drives it through a ſpace equal to its whole length. Therefore, the velocity of the power is in proportion to the velocity of the weight, as the length of the machine is to its thickneſs or height at the back; and the power and weight balance each other when the power is in proportion to the weight, as the thickneſs of the plane is to its length. All edge tools, which are chamfered (or ground down only on one ſide to the edge) are inclined planes, as far as the chamfer goes from the edge. See *Inclined* PLANE.

5. A *wedge*, in the common form, is like two inclined planes, joined together at their baſes; and the thickneſs of theſe planes (oppoſite their ſharp edges) makes the back of the wedge, to which the power of the ſledge or hammer is applied in cleaving of wood.

When two equal reſiſtances act perpendicularly againſt oppoſite ſides of the wedge, and a power acts perpendicularly againſt the back of the wedge, the velocity of the power is in proportion to the velocity of the reſiſtance on either ſide, as the length of the ſide is to half the thickneſs of the back: and the power balances the reſiſtance of the wood, when the power is in proportion to the reſiſtance, as half the thickneſs of the back of the wedge is to the length of either of its ſides, if the ſharp edge goes to the bottom

 of

of the cleft in the wood. But when the wood ſplits before the wedge, as it generally does, the power balances the reſiſtance, when the former is to the latter as half the thickneſs of the wedge (when it is driven quite into the wood) is to the whole length of the cleft below the back of the wedge. See WEDGE.

6. The *ſcrew* may be conſidered as if it were an inclined plane, wrapt round a cylinder. In this machine, the power muſt turn the cylinder quite round, in the time that the weight or reſiſtance (as in a common preſs) moves through a ſpace equal to the diſtance between the threads or ſpirals of the ſcrew. Therefore, the velocity of the power is in proportion to the velocity of the weight or reſiſtance, as the circumference of a circle, deſcribed by the power, is to the diſtance between the ſpirals of the ſcrew; and the power and reſiſtance balance each other, when the former is to the latter as the diſtance between the ſpirals is to the circumference of the circle deſcribed by the power. This machine, beſides the advantage peculiar to itſelf, has generally the benefit of the wheel and axle, on account of the winch or lever by which it is turned. See SCREW.

Of theſe ſix ſimple machines, all the moſt compound engines in the world are made. As the ſcrew includes the inclined plane, and two equally inclined planes make the wedge, we have all the mechanical powers combined together in a common jack, if it be turned by the fly; for then we have alſo the lever, the wheel and axle, and the pullies.

Thus, in a frame A B C D, (*Plate* XXXII. *Mechanics, fig.* 5.) faſtened by the nut O upon the ſtand O O, and held together by the pillars V W and B *q*, is adapted firſt the piece E F, whoſe fans or flies may be put in motion by the wind, or drawn by a hair faſtened at F, which repreſents the lever and balance: at right angles to this piece is joined the perpendicular ſpindle G H, having upon it the endleſs ſcrew H, which may be alſo conſidered as a wedge. This endleſs ſcrew or worm takes the ſkew teeth of the wheel K, which is the axis in peritrochio, and, in turning round, winds up the ſtring L M upon its axis, which paſſing round the pullies at M and N, or drawing by a tackle of five, raiſes the weight P. But as the ſcrew has no progreſſive motion on its axis, it cannot here be ſaid to comprehend the inclined plane; therefore, in order to make this machine take in all the mechanical powers, we may add the inclined plane, *r q* Q R, by making it reſt on the ground at Q R, and on the pillar *q* B, at *q r*, and thereby the force of the power drawing at F, will be farther increaſed in the proportion of Q T to T S. The whole force gained by this machine is found by comparing the ſpace gone through by the point F, with the height through which the weight is raiſed, in any determinate number of revolutions of F. An hundred pounds weight at P will be eaſily raiſed by the hair of a man's head drawing at F.

If an engine conſtructed in this manner be uſed for raiſing a weight, by means of a power applied to the fly, the power will balance the weight, if it be in proportion to the weight as the velocity of the weight is to the velocity of the fly. Now, conſidering how faſt the fly moves with reſpect to the motion of the weight, it is evident, that a crane, conſtructed in the manner of a common jack, would be an engine of very great power. But then the time loſt in raiſing the weight would alſo be very great: for, in any machine or engine whatever, the time loſt in working it will be as great as the power gained by it.

If machines or engines could be made without friction, the leaſt degree of power added to that which balances the weight would be ſufficient to raiſe it. In the lever, the friction is next to nothing; in the wheel and axle it is but ſmall; in the pullies it is very conſiderable; and in the inclined plane, wedge, and ſcrew, it is very great. The univerſal law or principle in all mechanical machines or engines, made to gain power, is, that the power gained will be always as great as the velocity of the power exceeds the velocity of the weight or reſiſtance: and, upon this principle, it is eaſy to compute the power, force, or advantage, of any ſimple machine or compound engine whatever.

E gr. If the body A (*Plate* XXXII. *Mechanics, fig.* 6.) be triple the body B, and each of them be ſo fixed to the extremities of a lever A B, whoſe fulcrum or fixed point is C, as that the diſtance of B C be triple the diſtance C A; the lever cannot be inclined on either ſide, but the ſpace B E, paſſed over by the leſs body, will be triple the ſpace A D, paſſed over by the great one. So that their motions or moments will be equal, and the two bodies in equilibrio.

Hence that noble challenge of Archimedes, *datis viribus, datum pondus movere;* for as the diſtance C B may be increaſed infinitely, the power or moment of A may be increaſed infinitely. So that the whole of mechanics is reduced to the following problem.

Any body, as A, *with its velocity* C, *and alſo any other body, as* B, *being given; to find the velocity neceſſary to make the moment or quantity of motion, in* B, *equal to the moment of* A, *the given body.* Here, ſince the moment of any body is equal to the rectangle under the velocity, and the quantity of matter; as B : A :: C : to a fourth term, which will be *c*, the celerity proper to B, to make its moment equal to that of A. Wherefore in any machine or engine, if the velocity of the power be made to the velocity of the weight, reciprocally as the weight is to the power, ſuch power will always ſuſtain, or, if the power be a little increaſed, it will move the weight.

Let, for inſtance, A B be a lever, whoſe fulcrum is at C, and let it be moved into the poſition *a* C *b*. Here, the velocity of any point in the lever is as the diſtance from the centre. For let the point A deſcribe the arc A *a*, and the point B the arc B *b*; then theſe arcs will be the ſpaces deſcribed by the two motions: but ſince the motions are both made in the ſame time, the ſpaces will be as the velocities. But it is plain, the arcs A *a* and B *b* will be to one another as the radii A C and C B, becauſe the ſectors A C *a* and B C *b* are ſimilar: wherefore the velocities of the points A and B are as their diſtances from the centre C.

Now if any powers be applied to the ends of the lever A and B, in order to raiſe its arms up and down; their force will be expounded by the perpendiculars S *a* and *b* N; which, being as the right ſines of the former arcs, *a* A and B *b*, will be to one another alſo as the radii A C and C B; wherefore the velocities of the powers are alſo as their diſtances from the centre. And ſince the moment of any body is as its weight, or gravitating force, and its velocity, conjunctly; if different powers of weights be applied to the lever, their moments will always be as the weights and the diſtances from the centre conjunctly. Wherefore, if to the ſame lever there be two powers or weights applied reciprocally proportional to their diſtances from the centre, their moments will be equal; and if they act contrarily, as in the caſe of a ſteel-yard, the lever will remain in an horizontal poſition, or the balance will be in equilibrio. And thus it is eaſy to conceive how the weight of one pound may be made to equibalance a thouſand, &c.

Hence alſo it is plain, that the force of the power is not at all increaſed by engines; only the velocity of the weight, in either lifting or drawing, is ſo diminiſhed by the application of the inſtrument, as that the moment of the weight is not greater than the force of the power. Thus, for inſtance, if if any force can raiſe a pound weight with a given velocity, it is impoſſible by any engine to effect, that the ſame power ſhall raiſe two pound weight with the ſame velocity: but by an engine it may be made to raiſe two pound weight, with half the velocity: or 1000 times the weight with $\frac{1}{1000}$ of the former velocity.

We ſhall here introduce into one view, an account of the principal methods that have occurred to us of explaining and demonſtrating the fundamental property of the ſeveral mechanical powers. It has been already obſerved, that, with regard to the lever, when any two forces act againſt each other on its arms, they will continue in equilibrio, if their quantities are inverſely as the diſtance between the points to which they are applied, and the point or fulcrum round which the lever turns. The demonſtration commonly aſcribed to Archimedes is founded upon this principle, that when any cylindric or priſmatic body is applied upon a lever, it has the ſame effect as if its whole weight was united and applied at the middle point of its axis. Let A B, *Plate* XXXII. *Mechanics*, *fig.* 7, be a cylinder, of an uniform texture, C its middle point; and it is manifeſt, that if the point C be ſupported, the equal halves of the cylinder, C A and C B, will balance each other about the point C, and the body will remain in equilibrio. Let the cylinder A B be diſtinguiſhed into any unequal parts, A D and D B; biſect A D in E, and D B in F; then a power applied at E, equal to the weight of the part A D, with a contrary direction, will ſuſtain it; and a power applied at F, equal to the weight of the part D B, with a contrary direction, will ſuſtain that part; ſo that theſe two powers acting at E and F, reſpectively equal to the weights of A D and D B, have preciſely the ſame effect as a prop at C, ſuſtaining the whole cylinder A B, and may be conſidered as in equilibrio with a power, acting at C, equal to the whole weight of the cylinder. But the diſtance $CE = CA - AE = \frac{1}{2}AB - \frac{1}{2}AD = \frac{1}{2}DB$; and, in like manner, the diſtance $CF = CB - BF = \frac{1}{2}AB - \frac{1}{2}DB = \frac{1}{2}AD$; conſequently C E is to C F as D B to A D; that is, as the power applied at F to the power applied at E, theſe being in equilibrio with the weight of the whole cylinder applied at C. From which it appears, that powers applied at E and F, which are to each other in the proportion of C F to C E, ſuſtain one another about the centre C.

It has been objected by M. Huygens and others, to this demonſtration of Archimedes, that when the whole cylinder is diſtinguiſhed into two ſegments, part of the weight of the greater ſegments acts on the ſame ſide of the fulcrum with the leſſer ſegment; and, therefore, when the whole weight of the greater ſegment is contracted into its middle point on one ſide of the fulcrum, and acts altogether againſt the leſſer ſegment, it requires ſome proof to ſhew, that this contracted weight will be balanced by the weight of the leſſer ſegment. M. Huygens propoſed a method of his own, depending on a poſtulatum aſſumed in common with Archimedes, and needing demonſtration, *viz.* that when equal bodies are placed on the arms of a lever, the one which is fartheſt from the fulcrum will prevail and raiſe the other up.

Sir Iſaac Newton demonſtrates the fundamental propoſition concerning the lever, from the reſolution of motion: let C, *fig.* 8, be the centre of motion in the lever K L; let A and B be any two powers applied to it at K and L, acting in the directions K A and L B. From the centre of motion, C, let C M and C N be perpendicular to thoſe directions in M and N; ſuppoſe C M to be leſs than C N, and from the centre C, at the diſtance C N, deſcribe the circle N H D, meeting K A in D. Let the power A be repreſented by D A, and let it be reſolved into the power D G acting in the direction C D, and the power D F perpendicular to C D, by completing the parallelogram A F D G. The power D G, acting in the direction C D from the centre of the circle, or wheel, D H N, towards its circumference, has no effect in turning it round the centre, from D toward H, and tends only to carry it off from that centre. It is the part D F only that endeavours to move the wheel from D towards H and N, and is totally employed in this effort. The power B may be conceived to be applied at N as well as at L, and to be wholly employed in endeavouring to turn the wheel the contrary way, from N towards H and D. If, therefore, the power B be equal to that part of A which is repreſented by D F, theſe efforts, being equal and oppoſite, muſt deſtroy each other's effect; that is, when the power B is to the power A, as D F to D A, or (becauſe of the ſimilarity of the triangles, A F D, D M C) as C M to C D or as C M to C N, then the powers muſt be in equilibrio; and thoſe powers always ſuſtain each other that are in the inverſe proportion of the diſtances of their directions from the centre of motion; or when the product of the one power multiplied by the diſtance of its direction from the centre, is equal to the product of the power on the other ſide multiplied by the like diſtance from it.

Mr. Maclaurin propoſes a new method of demonſtrating the law of equilibrium in the lever, which ſeems, he ſays, to be founded on the plaineſt and moſt evident principles: theſe principles are the following, *viz.* that if equal powers act at equal diſtances on different ſides of the fulcrum or centre of motion, with directions oppoſite and parallel to each other, they will have the ſame effect: and that, if gravity be ſuppoſed to act in parallel lines, and the fulcrum be between the bodies, whoſe powers are eſtimated, it muſt bear the ſum of their weights; becauſe the lever being loaded with thoſe weights, it muſt give way, if the fulcrum does not ſuſtain their ſum: but if the powers are on the ſame ſide of the fulcrum, in which caſe one of them muſt pull upwards whilſt the other pulls downwards, that there may be an equilibrium, it is then only loaded with the difference of the powers.

Suppoſing, therefore, firſt, two equal powers, A and B, *fig.* 9, acting in the directions A F, B H, to carry a body C, upon the lever A B, placed at C at equal diſtances from them; it is evident that, in this caſe, each of the powers A and B ſuſtains one-half of the weight C, by dividing it equally between them. Imagine now that the power A is taken away, and that, inſtead of reſting upon it, the end A of the lever reſts upon a prop at A; it is manifeſt that the power B, and the prop at A ſuſtain, as before, each one-half of the weight C; the prop now acting, in every reſpect, as the power at A before; and, the equilibrium continuing, it appears that, in this caſe, a power B equal to one-half of the weight C ſuſtains and balances it, when the diſtance of C from the prop A is one-half of the diſtance of B from the ſame; that is, when B is to C, as C A to B A, or $B \times BA = C \times CA$. From this ſimple inſtance we ſee, that powers act upon a lever not by their abſolute force only, but that their effect neceſſarily depends upon the diſtance of the point where they act from the prop, or centre of motion; and particularly, that a power balances a double power which acts at half its diſtance from the prop, on the ſame ſide of it, with an oppoſite direction.

The caſe when the two powers act on the different ſides of the prop, follows from this, by the principles already laid down. For let B H and C G (*fig.* 10.) repreſent the directions and forces with which the powers B and C act upon the lever; upon B A produced take A E equal to A C, or ½ A B, and in place of the power C G ſubſtitute

an

an equal power E K at E, with an oppofite direction; and, by the firft of thofe principles, this power E K will have the fame effect as C G, only the prop or centre of motion A will now fuftain the fum of the forces E K and B H, by the fecond of thofe principles. But the equilibrium between the powers B H and E K will continue as it was before, between B H and C G; fo that the powers B H and E K will be in equilibrio, when the power B H is one-half of E K, and the diftance of E K from the prop A is one-half of the diftance of B H from the fame; that is, when the power at B is to the power at E, as A E to A B, or $B \times BA = E \times EA$. In this cafe, the prop A being loaded with both the powers B and E, which act with the fame direction, its re-action muft be equal to their fum, $EK + BH = 3\,BH$, and muft be in the oppofite direction A F. In place of this re-action, let us now (*fig.* 11.) fubftitute a power A F at A, equal to thrice B H; and in place of the power E K, let us fubftitute a prop at E, fuftaining that end of the lever B E; and fince the equilibrium continues as before, it follows that the prop or centre of motion, being at E, the power B H fuftains the power A F, which is triple of B H, when the diftance of B H from the prop E is triple of the diftance of the power A F from the fame, that is, when $BH \times BE = AF \times AE$.

If we fuppofe the power E K to remain (*fig.* 12.) but the end B of the lever E B to reft upon a prop, then the powers A F and E K will fuftain and balance each other, the prop at B now coming in place of the power B H; in which $AF = 3\,BH$, and $EK = 2\,BH$; fo that A F is to E K as 3 to 2; and the diftances E B and A B being in the fame proportion, it appears that when two powers in the proportion of three to two act upon a lever on the fame fide of the prop, or centre of motion, with oppofite directions, at diftances in the proportion of two to three, they then fuftain each other. We have demonftrated therefore, that when the powers are in the proportion either of two to one, or of three to one, or of three to two, and the diftances of their application from the centre of motion are in the inverfe proportion, then thofe powers balance each other, or are in equilibrio.

Upon B E produced (*fig.* 13.) take $EL = EA$; and in place of the power A F fubftitute a power $LM = AF$, but with a contrary direction; this power L M will have the fame effect to turn the lever round the centre of motion E as A F had; confequently it will be in equilibrio with the power B H, as A F was. Therefore, when two powers L M and B H, in the proportion of three to one, act upon a lever with the fame direction, they are in equilibrio, if their diftances from the centre of motion L E and E B be in the ratio of one to three: that is, when $LM \times LE = BH \times BE$. In this cafe, the powers L M and B H acting with the fame direction, the prop E muft fuftain their fum $LM + BH = 4\,BH$, by the fecond principle above premifed. Therefore a power at L, as 3, and a power acting at B with the fame direction, as 1, are fuftained by a power acting at E, with a contrary direction, as 4. From which it follows, by fubftituting in the place of the power L M a prop at L, that a power at B, as 1, fuftains a power at E, as 4, acting with a contrary direction, when B L is to E L as 4 to 1; that is, when the powers are inverfely as their diftances from the prop, or centre of motion. By fubftituting the prop at B in the place of the power B H, it appears that a power L M at L, as 3, fuftains a power, acting with an oppofite direction at E, as 4, when their diftances L B and E B, from the prop B, are to each other as 4 to 3, or when $LM \times LB = EK \times EB$. By taking upon L B produced $Be = BE$ (*fig.* 14.), and in place of the power at E, fubftituting an equal power at *e* with a contrary direction, it appears, that a power at L, as 3, fuftains a power acting at *e*, with the fame direction, as 4, when the diftance L B is to the diftance *e* B, as 4 to 3. In this cafe, the prop at B fuftains the fum of the powers acting at L and *e*, that is, a power equal to feven times B H. From which it follows, by fubftituting a prop at L or *e*, in place of the powers that act there, that a power at *e*, as 4, fuftains a power at B, as 7, about the centre of motion L, when their diftances from it, *e* L, B L, are to each other as 7 to 4: and that a power at L, as 3, fuftains the power at B, as 7, about the centre of motion *e*, when their diftances from it, L *e* and B *e*, are to each other as 7 to 3.

By proceeding in this manner it appears, that when the powers are to each other as number to number, and when their diftances from the centre of motion are in the inverfe ratio of the fame numbers, then the powers fuftain each other, or are in equilibrio. From which it is eafy to fhew, in general, that when the powers are to each other in any ratio, though incommenfurable, and the diftances of their application from the centre of motion in the fame inverfe ratio, then they are in equilibrio; becaufe the ratio of incommenfurable quantities may be always limited to any degree of exactnefs at pleafure, between a greater and a leffer ratio of number to number. To Mr. Maclaurin's demonftration it has been objected, that it cannot be applied when the arms of the lever are incommenfurable, and as it cannot conclude generally, it muft, therefore, be imperfect.

Dr. Hamilton, having obferved that thefe feveral methods of demonftrating the fundamental property of the lever are liable to objections, propofes a new proof, depending on the following poftulatum, *viz.* if a force be uniformly diffufed over a right line, fo that an equal part of the force acts upon every point of the line, and if the whole force acts according to one and the fame plane, this force will be fuftained, and the line kept in equilibrio, by a fingle force applied to the middle point of the line equal to the diffufed force, and acting in a contrary direction. He alfo premifes this lemma: if a right line be divided into two fegments, the diftances between the middle of the whole line and the middle points of the fegments, will be inverfely as the fegments. This is felf-evident when the fegments are equal; and, when they are unequal, fince half of the whole line is equal to half of the greater and half of the leffer fegment, it is plain that the diftance between the middle of the whole line and the middle of one fegment, muft be equal to half of the other fegment, fo that thefe diftances muft be to each other inverfely as the fegments.

Let the line G H, then, *fig.* 15, whofe middle point is D, be divided into the unequal fegments G L and L H, whofe middle points are C and F, and let two forces or weights, A and B, which are to each other as the fegments G D and L H, be applied to their middle points C and F, and let them act perpendicularly on the line G H: then, (by the lemma) the weights A and B will be to each other inverfely as C D and F D (the diftances of the points C and F, to which they are applied, from the middle of the whole line); if then a third force or weight E, equal to the fum of the forces A and B, be applied to the point D, and acts on the line in an oppofite direction; I fay thefe three forces will fuftain each other, and keep the line in equilibrio. For let us fuppofe the force E to be removed, and inftead of it another force, equal alfo to the fum of A and B, to be uniformly diffufed over the whole line G H, and to act directly againft the forces A and B, then the part of this force which acts on the fegment G L, will be equal to the force A, and therefore will be fuftained by it (poftulatum);

latum); and the other part, which is diffused over the segment L H, will be equal to and sustained by the force B, so that the forces A and B will sustain this diffused force and keep the line in equilibrio. Let now two other forces act also on this line in opposite directions, one of them the force E acting on the point D, as it was first supposed to do, and the other an uniformly diffused force equal to E (and consequently equal to the other diffused force), then these two additional forces will also balance each other, and therefore the equilibrium will still remain. So that the two forces A and B, and a diffused force acting on one side of the line sustains the force E, and a diffused force acting on the other side: but it is manifest, that in this equilibrium, the two diffused forces acting on opposite sides are perfectly equivalent, and therefore if they are taken away from both sides, the equilibrium must still remain. Hence it appears that the three weights or forces A, B, and E, any two of which are, (by the construction) to each other inversely as their distances from the third, will sustain each other and keep the line on which they act in equilibrio; which is the first and most simple case of the property of the lever; for here the directions of the weights are supposed to be perpendicular to the line on which they act, and it is evident that, if one of the points C, D, or F be fixed or considered as a fulcrum, the weights acting on the other two points will continue to support each other. The second case of the property of the lever is easily deduced from the first; for when two weights act on the arms of a lever in oblique directions, and are to each other inversely as the perpendicular distances of the lines of direction from the centre of motion, then by the resolution of forces, it is easily proved that the parts of those forces which act perpendicularly on the arms of the lever, and which only are exerted to turn the lever, are to each other inversely as the lengths of those arms; and therefore by the first case they must balance each other.

From what has been above demonstrated, it appears, that the powers with which any two forces move or endeavour to move the arms of a lever, are as the rectangles, under lines proportional to the forces, and the perpendicular distances of their lines of direction from the fulcrum; and also that when two bodies acting on the arms of a lever sustain each other, if one of them be removed farther from the fulcrum, it will preponderate; but if it be brought nearer to the fulcrum, the other weight will prevail: because the product to which its force is proportional will be increased in the first case, and diminished in the second.

When a weight is to be raised by means of an axle and wheel, it is fastened to a chord that goes round the axle, and the power, which is to raise it, is hung to a chord that goes round the wheel. If then the power be to the weight as the radius of the axle to the radius of the wheel, it will just support that weight; as will easily appear from what was proved of the lever. For the axle and wheel may be considered as a lever, whose fulcrum is a line passing through the centre of the wheel and middle of the axle, and whose long and short arms are the radii of the wheel and axle which are parallel to the horizon, and from whose extremities the chords hang perpendicularly. And thus an axle and wheel may be looked upon as a kind of perpetual lever, on whose arms the power and weight always act perpendicularly, though the lever turns round its fulcrum. And in like manner, when wheels and axles move each other by means of teeth on their peripheries, such a machine is really a perpetual compound lever; and, by considering it as such, we may compute the proportion of any power to the weight it is able to sustain by the help of such an engine. And since the radii of two contiguous wheels, whose teeth are applied to each other, are as the number of teeth in each, or inversely as the number of revolutions, which they make in the same time: we may, in the computation, instead of the ratio of these radii, put the ratio of the number of teeth on each wheel; or the inverse ratio of the number of revolutions they make in the same time.

The most natural method of explaining the effects of the pulley, that is, of computing the proportion of any power to the weight it can sustain by means of any system of pullies, is, by considering that every moveable pulley hangs by two ropes equally stretched, which must bear equal parts of the weight: and, therefore, when one and the same rope goes round several fixed and moveable pullies, since all its parts on each side of the pullies are equally stretched, the whole weight must be divided equally amongst all the ropes by which the moveable pullies hang. And consequently if the power which acts on one rope be equal to the weight divided by the number of ropes, or double the number of moveable pullies, that power must sustain the weight.

The several cases in which the wedge is applied may be comprehended in one general proposition: let the equicrural triangle A B C (*fig.* 16.) represent a wedge, the lines A B and C B will be the sides of the wedge, A C its base, or back, and its height will be the line P B bisecting the base A C, and also the vertical angle A B C.

When any two resisting forces act on the sides of a wedge, in directions which make equal angles with the sides, (as they are always supposed to do,) a power acting perpendicularly at P on the base of the wedge will keep the resisting forces in equilibrio, when it is to the sum of these forces, as the sine of half the vertical angle of the wedge, to the sine of the angle which the directions of the forces contain with the sides of the wedge.

For let E and F be two bodies acting on the sides of the wedge, and let them be first supposed to act in the directions E P and F P perpendicular to the sides; then since the power P acts perpendicularly on the base A C, if these three forces keep the wedge in equilibrio, they will be to each other, as the sides of a triangle to which their directions are parallel, or (which is the same thing) as the sides of the triangle A B C, to which their directions are perpendicular. Therefore, the power P is to the sum of the resisting forces which it sustains as A C, the base of the wedge, to the sum of the sides, or as P A, half the base, to A B, one of the sides; but P A is to A B as the sine of P B A, half the vertical angle of the wedge, to the radius which is the sine of a right angle, and the directions of the resisting forces are supposed in this case to contain a right angle with the sides of the wedge.

Let now the resisting bodies E and F be supposed to act on the wedge in directions parallel to the lines D P and O P, which make oblique angles with its sides, draw E G and F K perpendicular to those lines. From what has been proved, it appears that the power P is to the force with which it is able, by means of the wedge, to protrude the resisting bodies in the directions P E and P F, as the sine of half the vertical angle to the radius; let this protruding force be expressed by the line P E, and let it be resolved into two forces expressed by the lines P G and G E, the former of these only will act in opposition to the resisting bodies, therefore the whole protruding force of the power is to the force with which it acts against the resisting bodies E and F in the directions P D and P O as P E to P G, or (because the triangles E P G and D P E are similar) as P D to P E, that is, as the radius to the sine of the angle P D E; compounding, therefore, the ratio of the sine of half the vertical angle to the radius, with the ratio of the radius to the sine of the angle P D E,

the

the power P, when the wedge is kept in equilibrio, will be to the force with which it protrudes the resisting bodies in directions opposite to those in which they act, as the sine of half the vertical angle to the sine of the angle P D E or P O F, which the directions of the resisting forces contain with the sides of the wedge.

Hence, when the directions in which resisting bodies act on a wedge are given, we may easily find two lines that will express the proportion between the resistance and the power which sustains it by means of the wedge. For from P, the middle point of the wedge, draw the line P D meeting one of the sides, and parallel to the direction in which the resisting force acts on that side, then the power will be to the resistance as P D to P B the height of the wedge. For P D and P B are to each other as the sines of the opposite angles, in the triangle P B D, that is, as the sines of half the vertical angle, and the angle which the direction of the resisting force contains with the side of the wedge.

From what has been demonstrated we may deduce the proportion of the power to the resistance it is able to sustain, in all the cases in which the wedge is applied.

First, when, in cleaving timber, the wedge fills the cleft, then the resistance of the timber acts perpendicularly on the sides of the wedge; therefore, in this case, when the power which drives the wedge is to the cohesive force of the timber as half the base to one side of the wedge, the power and resistance will be in equilibrio.

Secondly, when the wedge does not exactly fill the cleft, which generally happens because the wood splits to some distance before the wedge: let E L F represent a cleft, into which the wedge A B C is partly driven; as the resisting force of the timber must act on the wedge in directions perpendicular to the sides of the cleft, draw the line P D in a direction perpendicular to E L, the side of the cleft, and meeting the side of the wedge in D; then the power driving the wedge, and the resistance of the timber, when they balance, will be to each other as the line P D to P B, the height of the wedge.

Thirdly, when a wedge is employed to separate two bodies that lie together on a horizontal plane, for instance two blocks of stone; as these bodies must recede from each other in horizontal directions, their resistance must act on the wedge in lines parallel to its base C A; therefore, the power which drives the wedge will balance the resistance, when they are to each other as P A, half the breadth of the wedge, to P B its height; and then any additional force, sufficient to overcome the resistance arising from the friction of the bodies on the horizontal plane, will separate them from each other.

With respect to the inclined plane: let the line A B, (*fig.* 17.) represent the length of an inclined plane, A D its height, and the line B D we may call its base. Let the circular body G E F be supposed to rest on the inclined plane, and to be kept from falling down it by a string C S tied to its centre C. Then the force with which this body stretches the string will be to its whole weight as the sine of A B D, the angle of elevation, to the sine of the angle which the string contains with a line perpendicular to A B, the length of the plane. For let the radius C E be drawn perpendicular to the horizon, and C F perpendicular to A B, and from E draw E O parallel to the string, and meeting C F in O: then, as the body continues at rest, and is urged by three forces, to wit, by its weight in the direction C E, by the re-action of the plane in the direction F C, and by the re-action of the string in the direction E O; the re-action of the string, or the force by which it is stretched, is to the weight of the body as E O to C E; that is, as the sine of (the angle E C O, which is equal to) A B D, the angle of elevation, to the sine of the angle E O C, equal to S C O, the angle which the string contains, with the line C F perpendicular to A B, the length of the plane.

When, therefore, the string is parallel to the length of the plane, the force with which it is stretched, or with which the body tends down the inclined plane, is to its whole weight, as the sine of the angle of elevation to the radius, or as the height of the plane to the length. And in the same manner it may be shewn, that when the string is parallel to B D, the base of the plain, the force with which it is stretched is to the weight of the body as A D to B D, that is, as the height of the plane to its base. If we suppose the string, which supports the body G E F, to be fastened at S, and that a force by acting on the line A D, the height of the plane, in a direction parallel to the base B D, drives the inclined plane under the body, and by that means makes it rise to a direction parallel to A D: then, from what was proved in the third case of the wedge, it will appear, that this force must be to the weight of the body as A D to B D, or rather in a proportion somewhat greater; if it makes the plane move on and the body rise.

From this last observation we may clearly shew the nature and force of the screw; a machine of great efficacy in raising weights, or in pressing bodies closely together. For if the triangle A B D be turned round a cylinder whose periphery is equal to B D, then the length of the inclined plane B A will rise round the cylinder in a spiral manner, and form what is called the thread of the screw, and we may suppose it continued in the same manner round the cylinder, from one end to the other; and A D, the height of the inclined plane, will be every where the distance between two contiguous threads of this screw, which is called a convex screw. And a concave screw may be formed to fit this exactly, if an inclined plane every way like the former be turned round the inside of a hollow cylinder, whose periphery is somewhat larger than that of the other. Let us now suppose the concave screw to be fixed, and the convex one to be fitted into it, and a weight to be laid on the top of the convex screw: then, if a power be applied to the periphery of this convex screw to turn it round, at every revolution the weight will be raised up through a space equal to the distance between the two contiguous threads, that is, to the line A D, the height of the inclined plane B A; therefore, since this power applied to the periphery acts in a direction parallel to B D, it must be to the weight it raises as A D to B D, or as the distance between two contiguous threads, to the periphery of the convex screw.

The distance between two contiguous threads is to be measured by a line parallel to the axle; if we now suppose that a handspike or handle is inserted into the bottom of the convex screw, and that the power which turns the screw is applied to the extremity of this handle, which is generally the case; then as the power is removed farther from the axis of motion, its force will be so much increased, and therefore so much may the power itself be diminished. So that the power which, acting on the end of a handle, sustains a weight by means of a screw, will be to that weight, as the distance between two contiguous threads of the screw, to the periphery described by the end of the handle. In this case we may consider the machine as composed of a screw and a lever, or, as sir Isaac Newton expresseth it, *Cuneus a vecte impulsus.*

Professor Vince, premising that Dr. Hamilton's demonstration depends upon this proposition, that when a body is at rest, and acted upon by three forces, they will be as the three sides of a triangle parallel to the directions of the forces,

forces, allows this principle to be true, when the three forces act at any point of a body; but, conſidering the lever as the body, the three forces act at different points, and therefore the principle, as applied by the author, is certainly not applicable. If in this demonſtration we ſuppoſe a plane body, in which the three forces act, inſtead of ſimply a lever, then the three forces being actually directed to the ſame point of the body, the body would be at reſt. But in reaſoning from this to the caſe of the lever, the ſame difficulties would ariſe, as in the proof of ſir I. Newton. But admitting that all other objections could be removed, the demonſtration fails when any two of the forces are parallel. Another demonſtration is founded upon this principle, that if two nonelaſtic bodies meet with equal quantities of motion, they will, after impact, continue at reſt; and hence it is concluded, that if a lever which is in equilibrio be put in motion, the motions of the two bodies muſt be equal; and therefore the preſſures of theſe bodies upon the lever at reſt, to put it in motion, muſt be as their motions. Now in the firſt place, this is comparing the effects of preſſure and motion, the relation of the meaſures of which, or whether they admit of any relation, we are totally unacquainted with. Moreover, they act under very different circumſtances; for in the former caſe, the bodies acted immediately on each other, and in the latter, they act by means of a lever, the properties of which we are ſuppoſed to be ignorant of. When forces act on a body, conſidered as a point, or directly againſt the ſame point of any body, we only eſtimate the effect of theſe forces to move the body out of its place, and no rotatory motion is either generated, or any cauſes to produce it, conſidered in the inveſtigation. When we, therefore, apply the ſame propoſition to inveſtigate the effect of forces to generate a rotatory motion, we manifeſtly apply it to a caſe which is not contained in it, nor to which there is a ſingle principle in the propoſition applicable. The demonſtration given by Mr. Landen, in his Memoirs, is founded upon ſelf-evident principles, nor does our author ſee any objections to his reaſoning upon them. But as his inveſtigation conſiſts of ſeveral caſes, and is beſides very long and tedious, ſomething more ſimple is ſtill much to be wiſhed for, proper to be introduced in an elementary treatiſe of mechanics, ſo as not to perplex the young ſtudent either by the length of the demonſtration, or want of evidence in its principles. What the ingenious Profeſſor propoſes to offer will, he hopes, render the whole buſineſs not only very ſimple, but alſo perfectly ſatisfactory.

The demonſtration given by Archimedes would be very ſatisfactory and elegant, provided the principle on which it is founded could be clearly proved; *viz. that two equal powers at the extremities, or their ſum at the middle of a lever, would have equal effects to move it about any point.* Now, that the effects will be the ſame, ſo far as reſpects any *progreſſive* motion being communicated to the lever when at liberty to move freely, is ſufficiently clear; but there is no evidence whatever that the effects will be the ſame to give the lever a *rotatory* motion about any point, becauſe a very different motion is then produced, and we are ſuppoſed to know nothing about the efficacy of a force at different diſtances from the fulcrum to produce ſuch a motion. Beſides, the two motions are not only different, but the *ſame* forces are known to produce *different* effects in the two caſes; for in the former caſe the two *equal* powers at the extremities of the arms produce *equal* effects in generating a *progreſſive* motion; but in the latter caſe they do *not* produce *equal* effects in generating a *rotatory* motion. We cannot therefore reaſon from one to the other. The principle, however, may be thus proved.

Let A, C, (*fig.* 18.) be two equal bodies placed on a ſtraight lever, A P, moveable about P; biſect A C in B, produce P A to Q, and take B Q = B P, and ſuppoſe the end Q to be ſuſtained by a prop. Then as A and C are ſimilarly ſituated in reſpect to each end of the lever, that is, A P = C Q, and A Q = C P, the prop and fulcrum muſt bear equal parts of the whole weight; and therefore the prop at Q will be preſſed with a weight equal to A. Now take away the weights A and C, and put a weight at B equal to their ſum; and then the weight at B being equally diſtant from Q and P, the prop and fulcrum muſt ſuſtain equal parts of the whole weight, and therefore the prop will now alſo ſuſtain a weight equal to A. Hence if the prop Q be taken away, the moving force to turn the lever about P in both caſes muſt evidently be the ſame; therefore the effects of A and C upon the lever to turn it about any point are the ſame as when they are both placed in the middle point between them. And the ſame is manifeſtly true if A and C be placed without the fulcrum and prop. If, therefore, A C be a cylindrical lever of uniform denſity, its effect to turn itſelf about any point will be the ſame as if the whole were collected into the middle point B; which follows from what has been already proved, by conceiving the whole cylinder to be divided into an infinite number of laminæ perpendicular to its axis, of equal thickneſſes.

The principle, therefore, aſſumed by Archimedes is thus eſtabliſhed upon the moſt ſelf-evident principle, that is, that *equal* bodies at *equal* diſtances muſt produce *equal* effects; which is manifeſt from this conſideration, that when *all* the circumſtances in the cauſe are equal, the effects muſt be equal. Thus the whole demonſtration of Archimedes is rendered perfectly complete, and at the ſame time it is very ſhort and ſimple. The other part of the demonſtration we ſhall here inſert, for the uſe of thoſe who may not be acquainted with it.

Let X Y (*fig.* 19.) be a cylinder, which biſect in A, on which point it would manifeſtly reſt. Take any point Z, and biſect Z X in B, and Z Y in C; then, from what has been proved, the effects of the two parts Z X, Z Y to turn the lever about A is the ſame as if the weight of each part were collected into B and C reſpectively, which weights are manifeſtly as Z X, Z Y, and which therefore conceive to be placed at B and C. Now $AB = AX - XB = \frac{1}{2}XY - \frac{1}{2}XZ = \frac{1}{2}YZ$; and $AC = AY - YC = \frac{1}{2}XY - \frac{1}{2}ZY = \frac{1}{2}XZ$; conſequently $AB : AC :: \frac{1}{2}YZ : \frac{1}{2}XZ :: YZ : XZ ::$ the weight at C : the weight at B.

The property of the ſtraight lever being thus eſtabliſhed, every thing relative to the bent lever immediately follows. See Maclaurin's Account of ſir Iſaac Newton's Phil. Diſc. book ii. chap. 3. Hamilton's Phil. Eſſ. eſſ. 1. or Phil. Tranſ. liii. p. 116. Phil. Tranſ. vol. lxxxiv. art. v. p. 33, &c.

Mechanical is alſo applied to a kind of *reaſoning*, which of late has got great ground, both in phyſics and medicine; thus denominated, as being conformable to what is uſed in the contrivance, and accounting for the properties and operations of machines. See Medicine.

Mechanical is alſo uſed, in *Mathematics*, to ſignify a conſtruction or proof of ſome problem, not done in an accurate and geometrical manner, but coarſely and unartfully, or by the aſſiſtance of inſtruments; as are moſt problems relating to the duplicature of the cube, and the quadrature of the circle.

Mechanical *Arts*. See Arts.

Mechanical *Curve*. See *Tranſcendental* Curve.

Mechanical *Pathology*, the ſyſtem of medicine adopted by Borelli, Pitcairn, and others, at the end of the ſeventeenth and beginning of the eighteenth centuries, by which they endeavoured to explain the phenomena of diſeaſe upon the principles of mechanical philoſophy; principles which were very partially applicable to the operations of animal life;

life; the fyftem, therefore, was exploded by the more philofophical refearches into the laws of the fenforial power, or nervous energy, peculiar to living beings, by the pathologifts of fucceeding times. See MEDICINE, *Hiftory of*, near the end.

MECHELEN, in *Geography*, a town of France, in the department of the Lower Meufe, and chief place of a canton, in the diftrict of Maeftricht. The place contains 906, and the canton 7736 inhabitants, on a territory of 390 kiliometres, in 17 communes.

MECHLIN. See MALINES.

MECHOACAN, a province or large diftrict, in the domain of Mexico, bounded on the N. by part of Guafteca, or Panuco, and the provinces of Zacatecas and Guadalajara, on the E. by another part of Guafteca, and Mexico proper, and on the S. by the latter and the South fea, which, together with Xalifco or New Galicia, bounds it alfo on the W. and N.W. It extends about 210 miles along the coaft, and ftill further inland. The air is fingularly healthy, and the foil very fertile. In this province are mines of filver, and, as it has been faid, fome of gold and copper. Among its productions we may reckon maize and cotton, the cacao or chocolate nut, the root mechoacan, feveral odoriferous gums, and balfam, farfaparilla, ambergris, vanillas, caffia, honey, wax, &c. The natives, fince they have been incorporated with the Spaniards, have acquired the knowledge of feveral trades, and are curious in the manufacture of cabinets, weaving filk, and earthen pottery; and they particularly excel in making images of fmall feathers, equal to the moft exquifite painting. The country is infefted with foxes, fquirrels, lions, wild dogs, and tygers; but it has alfo a numerous breed of excellent horfes for the faddle or harnefs. The fea, as well as its lakes and rivers, fupply abundance of excellent fifh. In this province there are two confiderable lakes one of which gave name to the lake, implying "fifhery," as it ufed anciently to fupply the capital. This lake is fituated on the N. of Pafquaro, the capital of the province, while Valladolid, or Mechoacan, has only the bifhopric. According to Alcedo, it is about 12 leagues in circumference, probably about 40 Englifh miles, perhaps equalling that of Tezeuco, though reprefented in our maps as of far inferior fize. The fifh is exquifite; and many Indians dwell in picturefque iflets, occupied in fifhing, or bringing to the capital in canoes fifh, fruits, flowers, and pot-herbs. Mechoacan was formerly a kingdom, but the Spaniards have reduced it into a bifhopric, in which are about 200 towns of converted natives. As in this province there are fcarcely any harbours that deferve the name of ports, the greateft part of the trade is carried on by land.

MECHOACAN, or *Valladolid*, a city of Mexico, in the province of Mechoacan, and a bifhop's fee, fituated on a river near the W. fide of a lake, which abounds with fifh. It is large and well decorated; 108 miles W. of Mexico. N. lat. 20° 5'. W. long. 102° 11'.

MECHOACAN, *Mechoacanna*, called alfo *white jalap*, *white rhubarb*, and *American fcammony*, a medicinal root, taking its name from a province of Mexico, from whence it is brought in thin tranfverfe flices, like jalap, but larger and whiter. (See JALAP.) Mechoacan fcarcely yields one-fixth part fo much refin as jalap does. It is a fpecies of bindweed. See CONVOLVULUS.

Mechoacan was firft introduced about the year 1524, and ufed as a purgative before jalap, though the latter is now in more general ufe, as being found more efficacious: yet mechoacan is the milder and more gentle of the two, and on that account is preferable. The feat of its action is chiefly in the extreme parts; for which reafon it is accounted good in arthritic pains. It has the advantage of needing no preparation, or corrective; and of purging in its own proper fubftance, as it grows.

It purges ferous humours from all parts of the body; and helps the dropfy, jaundice, the rheumatifm, working with gentlenefs, and without griping; and, therefore, it is fit for weakly tender conftitutions; but by reafon that a larger quantity muft be given than moft people are willing to take, it is grown very much out of ufe. The dofe in fubftance is from one drachm to two or more.

M. Boulduc found, by analyfing it, that it contains twelve times as much falt as refin; but neither the faline nor refinous extract purge fo freely as the fubftance, even though taken in larger dofes; nor do they even purge fo eafily.

In the choice of mechoacan, prefer thofe pieces which are the browneft within, and whofe fubftance is the clofeft, and moft compact.

MECKENHEIM, in *Geography*, a town of France, in the department of the Rhine and Mofelle, feated on the Erfft; 7 miles S.S.W. of Bonn. N. lat. 50° 40'. E. long. 6° 57'.

MECKLENBURG, a town of the duchy of the fame name, anciently the capital of the Obotrites, and called by fome old hiftorians, probably on account of its extent, "Megapolis." Formerly it contained three convents, and in 1058 a bifhopric was founded. Since the founding of Wifmar, it has funk into a village; 2 miles S. of Wifmar.

MECKLENBURG, *Duchy of*, might formerly be faid to confift of three parts, *viz.* Schwerin, Güftrow, and Strelitz. But now only thofe of Schwerin and Strelitz are preferved, and the duchy of Mecklenburg Güftrow has fallen to the houfe of Schwerin, and, becoming incorporated with it, has loft its diftinctive name. Wifmar, which was formerly ceded to the Swedes, was afterwards purchafed of the king of Sweden, and now belongs to this branch of the houfe of Mecklenburg. This principality is bounded on the N. by the Baltic, on the E. by Pomerania, on the S. by Brandenburg, and on the W. by the territory of Lubeck and principality of Luneburg. When the Vandals, in a confiderable number, quitted this country in the fifth century, the Wends occupied their habitations, and became intermixed with the inhabitants that remained. Of thefe Wends, the moft confiderable tribe was that of the Obotrites, which had its own particular princes. From thefe defcended Prebiflau, who, in the 12th century, embraced the Chriftian religion, and rebuilt Mecklenburg, the ancient capital of the Obotrite princes, and took his name from it. His fon, Henry Borwin, was father of two princes, one of whom, *viz.* John, was the founder of the Mecklenburg line, and the other, *viz.* Nikolot, that of Wenden: but when this latter became extinct, the principality of Wenden devolved to the Mecklenburg branch, which was raifed to the dignity of duke by the emperor Charles IV. At the peace of Weftphalia, in 1648, Wifmar was ceded to the Swedes; but the diocefes of Schwerin and Ratzeburg were converted into temporal principalities. The Güftrow line failed, and, after fome difputes, a compromife took place at Hamburgh in 1701, on condition that the principality of Güftrow fhould be added to that of Schwerin, and that the principality of Ratzeburg, with fome other territories, fhould be annexed to that of Strelitz. At the fame time, the right of primogenitureihip, and the lineal fucceffion, were eftablifhed in both houfes, and the compact was ratified by the emperor Leopold. Two lines of the dukes of Mecklenburg are ftill fubfifting. The Schwerin line commenced in duke Frederic William; and the Strelitz line commenced in duke Adolphus Frederic II. The annual revenues of the Schwerin line are confiderable; and they were formerly rated

rated at 300,000 rix-dollars *per annum*. The duke of the Mecklenburg Strelitz line is faid to receive about 126,000 rix-dollars. The two duchies are divided into three circles, *viz.* Mecklenburg, Wenden, and Stargard.

The accounts of the foil and produce of this country are various and contradictory, even among the Mecklenburghers themfelves. According to the remonftrance of the nobility in 1718 to the imperial court againft the contribution exacted from them, the country was reprefented as full of lakes, which were almoft wholly unproductive, and as abounding with heaths, moors, woods, fens, and quarries. The foil was faid to be fandy, and capable of producing only a fmall quantity of rye and oats, and the paftures and meadows afforded but poor food for their fheep. The arable lands, even when well manured, produce for the moft part only barley, and very little wheat. The account given by Cluvier and Frank, who have defcribed the country, is very different. About $\frac{1}{8}$th of the country, they fay, is fandy, but the worft of the fandy land produces excellent rye, and, when fuffered to lie fallow, affords good fheep-walks; but the country in general is reprefented as incomparable, and not exceeded by Pomerania or Holftein. When well tilled and dunged, it yields barley and wheat, generally five, fix, or eight-fold. The country is interfperfed with delightful eminences, pleafant and profitable woods; nor is it deftitute of good fruit trees. Several forefts have been afforted, fens drained, and, together with the moors and quarries, improved into arable and pafture land. The commons and meadows, not inferior to thofe of Holftein and Pomerania, afford grafs in fuch plenty, that the country exports annually fome thoufands of cattle: the lakes and rivers, by their abundance of fifh, yield large revenues.

The principal rivers are the Elbe, Stor, Reckenitz, and Havel. In both duchies, exclufive of Roftock, are 45 great and fmall cities. The inhabitants of both duchies are Lutherans. In the country alfo there are fome congregations of Calvinifts; and in Schwerin the Roman Catholics are permitted the free exercife of their worfhip. The towns have German fchools, and Roftock has an univerfity. The country is not deftitute of woollen manufactures, tanners, leather-dreffers, tobacco-fpinners, and other trades. The exports of the country are corn, flax, hemp, hops, wax, honey, cattle, butter, cheefe, wool, and feveral kinds of wood.

MECKLENBURG, a county of Virginia, bounded S. by the ftate of North Carolina; containing 8332 free inhabitants, and 8676 flaves.—Alfo, a county of North Carolina, in the diftrict of Salifbury, bounded S. by the ftate of South Carolina; containing 10,317 inhabitants, of whom 1931 are flaves. Its chief town is Charlotte.

MECKLEY, a country of Thibet, occupying the fpace between Bengal and China, is bounded on the E. by China; on the S. by Ava, or the Birman empire; and on the W. by thick forefts, which feparate it from Bengal; it is about 350 miles in length, and 170 in breadth, fubject to the king of the Birman empire. N. lat. 22° 30′ to 27° 20′. E. long. 93° 20′ to 98° 40′. See ARRACAN.

MECKMUHL, a town of Wurtemberg, on the Jaxt; 32 miles N.N.E. of Stuttgart. N. lat 49° 20′. E. long. 9° 23′.

MECOBANISH, a lake of Canada. N. lat. 48° 58′. W. long. 83° 45′.

MECON, or MENAN, a large river of Afia, which rifes in the mountains of Thibet, between the 34th and 35th degrees of N. latitude, and purfuing a foutherly courfe bearing eaftward, it paffes through the Chinefe province of Yun-nan, the kingdom of Laos, Cambodia, &c., and runs into the Eaftern fea, about 200 miles S. of the city of Cambodia. At firft this river is called "Kiou-long," and retains this name till it enters Laos, when it takes the name of Mecon: when it enters Cambodia, it receives the name of the country, till at the city of Cambodia, it feparates into two branches, the eaftern of which is called Cambodia, or the Japanefe river, and the weftern Oubequeme.

MECONIUM, [illegible], from [illegible], *poppy*, in *Pharmacy*, is the juice of the heads or capfules of poppy, or papaver fomniferum, drawn by incifion, and dried.

Opium differs from the meconium, which, by the ancients, was made of the expreffed juice or decoction of the poppies, and it was deemed by them much more inactive in its operation than the opium. See OPIUM.

The college of London directs an extract of white poppy to be prepared by decoction of the poppy capfules in water, and fubfequent infpiffation. For this purpofe, take a pound of white poppy capfules bruifed, and a gallon of boiling water. Macerate for 24 hours; then boil down to four pints, ftrain the hot liquor, and evaporate it to a proper confiftence. This differs from opium, which is believed to be the concrete milky juice which exudes on making incifions into the frefh capfules, though probably fome additions are made to it. Six grains of this extract are about equivalent to one of opium; but much of the comparative narcotic power of the plant itfelf may depend upon the influence of climate. The feeds are firft to be feparated from the capfules, for they produce no narcotic effect; they yield oil and mucilage, and readily rub into an emulfion.

A decoction of poppy, decoctum pro fomento, P. L. 1787, fotus communis, P. L. 1745, is thus prepared: take of white poppy capfules bruifed four ounces, and of water four pints; boil for a quarter of an hour and ftrain. For various purpofes, efpecially fomentation, advantage is derived from the folution of the narcotic matter contained in poppy heads; this may, therefore, be confidered as an ufeful addition, and as reducing into form a decoction in very common ufe.

MECONIUM is alfo a black thick excrement, gathered in the inteftines of a child during the time of geftation.

In colour and confiftence it refembles pulp of caffia. It is alfo thought to refemble meconium, or juice of poppy; whence it takes its name. See INFANT.

MECRAN, or MEKRAN, in *Geography*, a large province of Perfia, extending to the Indian deferts, is bounded on the N. by Segeftan and Candahar; on the E. by Hindooftan; on the S. by the Indian fea; and on the W. by Kerman. This is the ancient Gadruftan, or Gedrofia. A chain of mountains croffes it, and divides it into two almoft equal parts. This province has been always unfertile, and full of deferts; and claffical geography, fays Pinkerton, here prefents only one mean town, called Pura, probably Borjian, on the moft W. frontier. The extenfive fea-coaft on the Indian ocean, far from being the feat of commerce, fcarcely prefents one harbour, being almoft an uniform line of fterility, inhabited by Arabs, like moft of the fouthern coafts of Perfia, which are divided by mountains and deferts from the fertile and cultivated land. Travellers in their journies are often ftopped, and fometimes overwhelmed by deep and moving fands. In this province water is fcarce, and it has few rivers. The capital is Kidge.

MECRINHOS, a town of Portugal, in the province of Tras los Montes; 24 miles S.E. of Mirandela.

MECZARA, a town of Africa, in the kingdom of Tambut.

MEDA, a town of Portugal, in the province of Beira; 20 miles N.E. of Pinhel.

MEDACO, a town of Africa, in the country of Meetka. N. lat. 14° 30'. E. long. 23° 20'.

MEDAL, Medalia, a ſmall figure, or piece of metal, in form of a coin, deſtined to preſerve to poſterity the portrait of ſome great man, or the memory of ſome illuſtrious action.

Scaliger derives the word from the Arabic *methalia*, a coin whereon is impreſſed the figure of a human head. Menage and Voſſius rather derive it from *metallum*. Du Cange obſerves, that the obolus was anciently called *medalia quaſi medietas nummi;* as being half of another coin.

Medals may be diſtinguiſhed by the metal of which they are made; which is commonly one of the three metals, *aurum*, *argentum*, and *æs*, ſignified by the three A's, which, on ſeveral coins, are placed after the name of the mint-maſter, *viz.* gold, ſilver, and copper, or braſs.

The moſt uſual purity of coined gold amounts to about 22 carats, two carats being deducted from the ſtandard of the utmoſt purity, which is fixed at 24 carats, and conſiſting of alloy. See Coin.

The moſt ancient gold coins exiſting, thoſe of Lydia and other ſtates in Aſia Minor, are not of the pureſt gold. Many of the earlieſt coins ſeem to be formed of the metal anciently called "electrum;" and conſiſting of gold and ſilver. But when Philip of Macedon coined the firſt gold of Greece, procured from the mines of Philippi in Thrace, the art of refining gold had attained great perfection, for his coins are of the utmoſt purity. They are rivalled, however, by thoſe of his ſon Alexander, and of other princes and cities within a few centuries of that age. The gold coins of the Egyptian Ptolemies are 23 carats three grains fine, with only one grain alloy. The Roman gold coinage is very pure from the earlieſt times, and remained in this ſtate till the reign of Severus. Pliny ſays, that moſt gold was found mixed with ſilver; of which the latter amounted to one-fifth. The metal was called "electrum." The moſt ancient ſilver is, like the gold, leſs pure than that of ſucceeding time, and this was particularly the caſe with that of the Greeks. The Roman ſilver was rather inferior to the preſent ſtandard, even from the beginning; but in the time of Severus very bad ſilver appeared, and continued till that of Diocletian. The braſs of the ancients, when pure, which is rather uncommon, conſiſted of two kinds; the red, or what the ancients called Cyprian braſs, which we call copper, and the yellow, or braſs. As medals of theſe metals are generally covered with patina, the difference has not excited attention; though in Roman coins braſs was double the value of copper; and the Greeks, it is ſuppoſed, followed the ſame rule.

The ancients had alſo numerous coins made of mixed metals. The firſt mixture was that of gold and ſilver, and called "*Electrum;*" which ſee. The next metal of value was Corinthian braſs, which was employed in the fabrication of vaſes and other ornamental toys; but it does not appear, according to Mr. Pinkerton, that they ever ſtruck a ſingle medal in this metal. The real fact is, that the coins, which ſome medallic authors have called Corinthian braſs, are only ſtruck as a modification of common braſs. The zinc which is mingled with the copper in the furnace for the manufacture of braſs, gives it a great variety of hues in proportion to the quality of the zinc, or of the copper. The beſt and fineſt of theſe hues belongs to what is now termed "Prince's metal," which ſeems to have been that which the firſt medalliſts called Corinthian braſs. Of Egyptian coins, ſtruck under the Roman emperors, ſome were at firſt of tolerable ſilver; but by degrees they degenerated into a metal, called by the French Medallic writers "Potin," being a mixture of copper and tin, with a little ſilver. Theſe coins are remarkably thick; but many of them are elegantly executed, in a peculiar ſtyle, with uncommon reverſes. There are, likewiſe, braſs coins of Egypt, of three ſizes, from the earlieſt Roman emperors there, and of a different fabrication. Some coins of that which is called large braſs, are of the mixtures now called pot-metal and bell-metal. After the time of Valerian and Gallienus coinage of braſs, with a ſmall addition of ſilver, is that authorized by the ſtate, being that of the "denarii aerii." The coins of lead or copper, plated with gold or ſilver, are thoſe of Roman forgers. Coins have been found in lead of undoubted antiquity. Some ſuch of Tigranes are mentioned as genuine by Jobert; but they are now well known to be forgeries. An ancient writer informs us, that tin money was iſſued by Dionyſius, one of the Sicilian tyrants; but no ſuch coins have been found. In Rome leaden coins muſt have been pretty ancient, for Plautus mentions them in one or two paſſages of his plays; and a few imperial ones have been found, but they are chiefly trial-pieces, in order to enable the artiſt to judge of the progreſs of the dye. Others are thoſe which have been plated by forgers, but the covering worn off.

It has been ſaid that there are alſo ſome medals compoſed of two different metals, not by melting them together, but either by plating over braſs or iron with ſilver; a ſort of falſe money, which had its riſe in the triumvirate of Auguſtus; or by laying a rim of a different metal round the edge of a medal. Thoſe of the latter ſort are called by antiquaries *contorniati*, from the French *contour*, which ſignifies the outline that defines a figure. See Contourniated.

It is conſidered as a certain rule in this ſcience, ſays Pinkerton, that none of the ancient money was caſt in moulds, except the moſt ancient and very large Roman braſs, vulgarly called weights, and other Italian pieces of that ſort. All other caſt coins are forgeries of ancient or modern times: for this was a manœuvre of the ancient forgers, as we learn from ſeveral Roman moulds which have been found, and which have led the unſkilful to imagine that the ancients firſt caſt their money in dyes, and then ſtamped it, to make the impreſſion more deep and ſharp. Dr. Jennings, in his "Introduction to the Knowledge of Medals, &c." 1764, 12mo., has fallen into this miſtake, beſides ſeveral others which are noticed by Mr. Pinkerton. The ancients, though ſtrangers to the art of impreſſing legends upon the edge of their money, like the "decus et tutamen" upon our crown pieces, and to the fine indentation obſervable on our gold, yet knew ſomething of crenating the edges of their coin. This they did by cutting out regular notches on the edges. Some of the Syrian coins, and of the Roman conſular, with a few other early ones, are ornamented in this manner. The former were caſt in this ſhape, then ſtruck; the latter was done by inciſion to prevent forgery, by ſhewing the inſide of the metal. They were anciently called "ſerrati," and Tacitus ſays, that the Germans preferred them to other Roman coins. But this was alſo imitated by the old forgers; and Mr. Pinkerton has in his poſſeſſion a ſerrated conſular coin, of which the inciſions, like the reſt, are plated with ſilver over copper.

Medals may again be diſtinguiſhed by their different ſizes. The ſize of the ancient medals is from three inches to one-fourth of an inch in diameter. Thoſe of the larger ſize or volume are called *medallions*. The others, which are very various, are ranked into three claſſes, *viz.* large, middle, and ſmall; and the claſs is determined, not ſo much by the breadth and thickneſs of the medal itſelf, as by the ſize of the

the head that is stamped upon it. The shape of medals is rather roundish than perfectly round. No Roman or Etruscan coins have been found of the globular form, or indented on the reverse, like the early Greek. The first Greek coins are small pieces of silver, while the Roman are large masses of copper. The former are struck; the latter are cast in moulds.

Medal, *the Parts of a*, are the two sides; one whereof is called the *face*, *head*, or *obverse*, the other the *reverse*.

On each side is the area, or field, which makes the middle of a medal; the rim, or border; and the exergue, which is beneath the ground whereon the figures represented are placed. (See Exergum.) On the two sides are distinguished the type, and the inscription or legend. The type, or device, is the figure represented; the legend is the writing, especially that around the medal; though, in the Greek medals, the inscription is frequently in the area. See Legend.

What we find in the exergue is frequently no more than some initial letters, whose meaning we are usually unacquainted with; though sometimes too they contain epochas, or words that may be accounted an inscription. The exergue contains sometimes the date of the coin, expressing in what consulship of the emperor it was struck: as cos III. upon the reverse of an Antoninus. Sometimes it signifies the place where it was struck, and to which the coin properly belonged, as S. M. AL. for *signa Moneta Alexandriæ*, upon the reverse of a Licinius. Sometimes the name of a province, the reduction of which the medal is designed to celebrate; as Judæa in the reverse of a Vespasian.

On the face of medals we have commonly the portrait of some great and illustrious person; usually, if not always, in profile. The coins of the kings of Macedon are the most ancient of any yet discovered on which portraits are found; and Alexander I., who began his reign about 500 years B.C. is the earliest monarch whose medals have yet been discovered. Then follow those kings and queens who reigned in Sicily, Caria, Cyprus, Heraclea, and Pontus. To these succeeds the series of kings of Egypt, Syria, the Cimmerian Bosphorus, Thrace, Bithynia, Parthia, Armenia, Damascus, Cappadocia, Paphlagonia, Pergamus, Galatia, Cilicia, Sparta, Pæonia, Epirus, Illyricum, Gaul, and the Alps. This series extends from the time of Alexander the Great to the birth of Christ, comprehending a period of about 330 years. The last series of ancient kings descends to the fourth century, and includes some of Thrace, the Bosphorus, and Parthia, those of Commagene, Edessa or Osrhoene, Mauritania, and Judæa. The portraits of the kings above enumerated are found on medals struck with Grecian characters.

The Roman emperors present a most distinct series from Julius, the first of them, to the destruction of Rome by the Goths, or even to a much later period, if the coins after this were not so barbarous as to destroy the beauty of the series while they add to its perfection. Of modern coins many proper serieses might be formed, consisting of the kings and other potentates of the different countries. Medals of illustrious men in modern times are not likewise wanting to form a collection.

The kings, upon Greek coins, have generally the diadem, without any other ornament. The side face is alway presented; though upon very ancient Greek coins of cities, and Roman consular coins, full faces are found of amazing relief and expression. Sometimes several heads are found on the same coin, either impressed on both sides, or only upon one. Thus the beautiful gold coin of Ptolemy Philadelphus, king of Egypt, bears his own head and that of Arsinoe, his queen, on one side; and those of his father and mother, Ptolemy I. and Berenice, on the other. Coins are found also of Antony and Cleopatra, Nero and Agrippina, Agrippina and Germanicus, and many others, both Greek and Roman. Sometimes two or more heads are found upon one side, while the other bears a reverse in the usual way. These heads are either *adverse*, that is, opposite to each other, face to face; or *joined*, and both looking one way. Of the adverse are coins of Licinius, father and son, and others. Joined heads are found on the finest Greek coins, as in that of Ptolemy above-mentioned, and in the Roman are Commodus and Marcia his concubine, and others. Sometimes real portraits are joined with ideal ones, as Carausius and Apollo, Posthumus and Hercules, &c. Sometimes three heads are found upon one side, as in that of Valerian, with his sons Gallienus and Valerian, &c. All such coins are very rare and valuable.

As for the ornaments of portraits, the chief is the diadem, or "vitta," which was a ribbon worn about the head, and tied in a floating knot behind, anciently the simple, but superlative, badge of kingly power. It is observable upon the Greek monarchic medals, from the earliest ages to the last; and is almost an infallible sign of the portrait of a prince. In the Roman coins it is seen on the consular one with Numa and Ancus; but never after, as Mr. Pinkerton apprehends, till the time of Licinius.

The Romans had such an abhorrence of this badge of kingly distinction, that their emperors had, for two centuries, wore the radiated crown, peculiar to the gods, before they dared to assume this tyrannic badge. However, in the family of Constantine the diadem became common, but divested of its ancient simplicity; being ornamented on either side with a row of pearls, and various other decorations. The radiated crown, at first, as in the posthumous coins of Augustus, a mark of deification, was, in little more than a century after, put upon most of the emperors' heads in their several medals. The crown of laurel, at first the honorary prize of conquerors, was afterwards commonly worn, at least in their medals, by all the Roman emperors from Julius, who was permitted by the senate to wear it always, in order to hide the baldness of his forehead. In the lower empire, the laurel is often held by a hand above the head, as a mark of piety. Agrippa appears on his coins with the rostral crown, a sign of naval victory or command, being made of gold, in resemblance of prows of ships tied together. He is likewise seen with the mural or turreted crown, the prize of first ascending the walls of an enemy's city. The oaken, or civic crown, is frequent on reverses, as of Galba and others; and was the badge of having saved the life of a citizen, or of many citizens. (See Crown.) Besides the diadem, the Greek princes sometimes appear with the laurel crown. The Arsacidæ, or kings of Parthia, wear a kind of sash round the head, with their hair in rows of curls like a wig. Tigranes, and the kings of Armenia, wear the tiara. Xerxes, a petty prince of Armenia, appears on a coin in a conic cap, with a diadem around it. Juba, the father, has a singular crown like a conic cap, all hung with pearls.

The successors of Alexander assumed different symbols of deity on the busts of their medals; such as the lion's skin of Hercules, surrounding the head of the first Seleucus; the horn placed behind the ear, an image of their strength and power, or of their being the successors of Alexander, called the son of Jupiter Ammon; the wing, placed in like manner behind the ear, symbolic of the rapidity of their conquests, quefts, or of their defcent from the god Mercury, &c. Pyrrhus, as Plutarch informs us, had a creft of goat's horns to his helmet; and the goat was a fymbol of Macedon. The fucceffors of Alexander might take this badge on that account. The helmet alfo appears on coins, as in thofe of Macedon under the Romans, which have Alexander's head, fometimes covered with a helmet. Probus has the helmet: and Conftantine I. has helmets of different forms, curioufly ornamented.

The Greek queens have the vitta or diadem. Moft queens of Egypt have the fceptre. The Roman empreffes never appear with the diadem, the variety of their head-dreffes compenfating the want of it. The remarkable part of the Roman head-drefs among the ladies was the "Sphendona," or fling, on the crown of the head, which was of gold, and fo prominent, as to be even remarkable on a coin. Sometimes the buft of an emprefs is fupported by a crefcent, denoting that fhe was the moon, as her hufband was the fun of the ftate. There are other fymbolic ornaments of the head obfervable on fome Roman coins. Such is the veil, or rather toga, drawn over the head, and feen on the bufts of Julius Cæfar, when Pontifex Maximus, and others. Latterly the veil was only a mark of confecration, and is common on coins of empreffes, as Fauftina and others. In the coins of Claudius Gothicus, it is firft found as a mark of the confecration of an emperor; and it was continued in thofe of Conftantius I., Maximian I., and Conftantine I. Thefe coins, fays Mr. Pinkerton, rank with thofe that are valuable for their rarity.

The "nimbus," or glory, now peculiar to the faints, was formerly applied to emperors. A nimbus appears round the head of Conftantine II., in a gold coin of that prince, and of Flavia Maxima Faufta, in a gold medallion; and of Juftinian in another. But the idea is as ancient as the reign of Auguftus. Havercamp gives a fingular coin, which has upon the reverfe of the common piece with the head of Rome, URBS ROMA, in large brafs. Conftantine I., fitting amid victories and genii, with a triple crown upon his head for Europe, Afia, and Africa: legend SECURITAS ROMÆ. This medal, fays Pinkerton, might haply have afforded a curious argument, in an ignorant age, for Conftantine's donation to the pope, and for the papal triple crown. But in fact the univerfal fpiritual power of the pope was totally unknown till the 12th century; before which time his election was obliged to be confirmed by the exarch of Ravenna, and afterwards by the emperor of Germany; and his temporal power is fo late as the beginning of the 16th century, only commencing in the crimes of Borgia. The buft alone is generally given on ancient coins; but fometimes half the body, or more; in which latter cafe the hands often appear, with tokens of majefty in them. Such is the globe, faid to have been introduced by Auguftus, to exprefs poffeffion of the world; the fceptre, fometimes confounded with the confular ftaff; the roll of parchment, fymbolic of legiflative power; and the handkerchief, expreffing that of the public games, where the emperor gave the fignal. Some princes hold the thunderbolt, fhewing that their power on earth was equal to that of Jupiter in heaven. Others hold an image of victory.

The reverfes of medals contain figures of deities at whole length, with their attributes and fymbols; public buildings and diverfions; allegorical reprefentations; ceremonies civil and religious; hiftorical and private events; figures of ancient ftatues; plants, animals, and other fubjects of natural hiftory: ancient magiftracies, with their infignia; and, in fhort, almoft every object of nature or art. Some reverfes bear the portrait of the queen, the fon, or the daughter of the prince who appears on the obverfe. Such are highly efteemed by antiquaries, not merely becaufe coins ftamped with portraits on both fides are valuable, but becaufe they identify the perfonage on the reverfe to have been the wife, the fon, or the daughter, of fuch a particular prince, and thus help in the adjuftment of a feries. Some medals with two portraits are very common; fuch are Auguftus reverfe of Caligula, and M. Aurelius reverfe of Antoninus Pius. The reverfes of the Roman coins have more of art and defign than the Greek; but the Greek have more exquifite relief and workmanfhip than the other. In the very ancient coins, no reverfe is found except a rude mark ftruck into the metal, as of an inftrument with four blunt points, on which the coin was ftruck. Afterwards, by degrees, we fee fome little image of a dolphin, or other animal, inferted into one of the departments of the rude mark, or into a hollow fquare. Then follows a perfect reverfe of a horfe, or the like, with a flight mark, and at length without any mark, of the hollow fquare. Some ancient Greek reverfes are ftruck in intaglio, not in cameo, hollow, not in relief. Such are thofe of Caulonia, Crotona, Metapontum, and fome other ancient cities of Græcia Magna. Thefe reverfes fometimes bear the fame type in intaglio, which the obverfe has in cameo; and fometimes they are quite different. When complete reverfes appear on the Greek coins, about 500 years B.C. they are of exquifite relief, minute finifh, and beauty. The very mufcles of men and animals are feen, and will bear infpection with the largeft magnifier, as ancient gems.

Of Roman coins, the reverfes are very uniform, the prow of a fhip, a car, or the like, till about 100 years B.C., when various reverfes appear on their confular coins in all metals. The variety and beauty of the Roman imperial reverfes are well known. The medallift much values thofe which have a number of figures, as the "Puellæ Fauftinianæ" of Fauftina, a gold coin no larger than a fixpence, which has twelve figures:—that of Trajan, "Regna adfignata," which has four:—the "Congiarium" of Nerva, with five:—the "Allocution" of Trajan, with feven; of Hadrian, with ten; of Probus, with twelve. Some Roman medals, to which no peculiar name has been appropriated by medallifts, have fmall figures on both fides, as the "Apolloni Sancto" of Julian II. Others have only a reverfe, as the noted "Spintriati," which have numerals I. II. &c. on the obverfe.

The figures of deities and perfonifications on the Roman coins, are commonly attended with their names, befides being diftinguifhed with their attributes. Thefe names, without an adjunct, are put down merely becaufe it was neceffary that the coin fhould have a legend. Thus, in a coin of Lucilla, Venus, though well known by the apple which fhe always holds in her hand, has neverthelefs the name round her, VENUS, without any addition. But an adjunct is moft commonly added, and this renders the infertion of the name very proper and neceffary, as in the inftance of a Neptune, with NEPTUNO REDUCI:—a Venus, with VENERI VICTRICI, and others fimilar. The like may be faid of the coins with a figure of Modefty, PUDICITIÆ AUGUSTÆ; of Virtue, VIRTUS AUGUSTI, &c.; for it is the legend which appropriates the virtue to the emperor or emprefs, and thus leaves no doubt as to the meaning of the reverfe.

In the Greek coins, a fuperior delicacy is obferved by not expreffing the name of the deity, but leaving it to the eafy interpretation of fixed fymbols. This remarkable difference is obfervable in the earlieft coins of the two countries, on which only the buft of the deity or perfonification is given. The

The Romans have almoſt always the name, as PIETAS, LIBERTAS, &c., while the Greeks content themſelves with giving Ceres with her wheaten garland; Jupiter with his mild countenance, laurel crown, and beard; Minerva with her helmet, &c. &c.

Mr. Pinkerton has given an account of the ſymbols found on the Greek coins, and alſo of thoſe very few on the Roman, which are not immediately illuſtrated by the legend of the medal. The principal deities ſymbolized in the Greek coins, as divided into male and female, are as follow: 1. JUPITER, in the firſt rank of gods, occurring frequently on reverſes of Alexander the Great, and eaſily known by his eagle and thunderbolt: when the buſt only occurs on obverſes of coins, it is known by the laurel crown, and placid bearded countenance. Jupiter Ammon is diſtinguiſhed by the ram's horn twiſting round his ear. 2. NEPTUNE ſeldom occurs on the coins of Greece; but when he appears, he is well known by the trident, or the dolphin, and is ſometimes drawn by ſea-horſes. His buſt has a trident behind. 3. APOLLO is frequently ſeen on the reverſes of the Syrian princes, and is known by the harp, the branch of laurel, or the tripod; ſometimes he has a bow and arrows. When the buſt only occurs, he has a fair young face, and is covered with laurel; and in the character of the ſun, his head is ſurrounded with rays. 4. MARS, often ſeen on Greek civic medals, is diſtinguiſhable by his armour, and ſometimes by a trophy on his ſhoulders. The buſt is known by the helmet and ferocious countenance. 5. MERCURY appears with the "caduceus," or wand twined with ſerpents, and the "marſupium," or purſe, which he holds in his hand. He is delineated as a youth, with a ſmall cap in his hand, and wings behind his ears and at his feet. The buſt is known by the cap, which reſembles a ſmall hat, and the wings. 6. ÆSCULAPIUS is remarkable on account of his buſhy beard, and his leaning on a club with a ſerpent twiſted round it. He is ſometimes ſeen with his wife Hygeia, or Health, and their little ſon Teleſphorus, or Convaleſcence, between them. 7. The attributes of BACCHUS are the tiger, the ſatyrs around him, the "thyrſus," or rod twiſted with ivy or vine, and the crown compoſed of one of thoſe plants. His buſt is known by the latter ſymbol, and by the diadem and horn. 8. The club, lion's ſkin, and ſinewy ſtrength, reveal HERCULES; with ſometimes the addition of a cup, denoting that wine inſpires courage, and the poplar tree, ſymbolic of vigour. He often appears as breaking the neck of the Nemæan lion, by cruſhing it in his arms. His buſt is common on the obverſe of coins of Alexander the Great, and other princes, and thoſe of Sicilian cities: it is that of a youth without a beard; with the lion's ſkin wrapped around it; and on the coins of Alexander has been erroneouſly taken for the portrait of that prince. He is ſometimes drawn with a beard, and called Hercules; without it he is denominated the young Hercules. 9. SERAPIS, one of the fantaſtic gods of Egypt, is known by his buſhy beard, and the meaſure upon his head. APIS appears as a bull, with a flower of the λῶτος, lotos, the water-lily of the Nile. Macrobius ſays it was a ſymbol of creation; and Jamblichus ſays that Oſiris was ſuppoſed to have his throne in it. (See LOTOS and LOTUS.) 10. HARPOCRATES, the god of ſilence, is known by the familiar token of putting his finger to his mouth. He has ſometimes the "ſiſtrum" in his left hand, which is a ſymbol common to moſt of the Egyptian deities. 11. CANOPUS is very common on the coins of Egypt, in the ſingular ſhape of a human head, placed upon a kind of pitcher. (See CANOPUS.) 12. To the above-mentioned ſymbolized gods we may ſubjoin the ΙΕΡΑ ΣΥΝΚΛΗΤΟΣ, and ΙΕΡΟΣ ΔΗΜΟΣ, the holy ſenate, and holy people, ſo frequent on Greek imperial coins. Theſe ideal perſons are commonly ſeen in the ſame image of an ancient bearded head, crowned with laurel: ſometimes both appear as youths.

Among the female deities, the firſt in dignity is, 1. JUNO known by the peacock, a bird ſacred to her from the fable of Argus. As the goddeſs of marriage, ſhe is veiled to the middle, and ſometimes to the toes. Her buſt is that of a beautiful young woman, ſometimes without any badge, which ſufficiently diſtinguiſhes her, as the reſt of the goddeſſes have badges; and ſometimes with a diadem. 2. The ſymbols of MINERVA conſiſt in her armour, with a ſpear in her right hand, and the "ægis," or ſhield with Meduſa's head, in the other; an owl commonly ſtanding by her. Her buſt is diſtinguiſhable by the helmet, which ſhe always wears: this is very common on the gold coins of Alexander the Great. 3. DIANA is manifeſt by the creſcent, by her bow and arrows, and often by her hounds. The Epheſian Diana, common upon Greek imperial coins, appears with a number of "mammæ," being ſuppoſed the ſame with univerſal nature; ſhe is ſupported by a couple of deer, and bears on her head a pannier of fruit. The buſt of Diana is known by the creſcent on her brow, and ſometimes by the bow or quiver engraven on one ſide. 4. VENUS is declared by the apple in her hand, the prize of beauty. Sometimes ſhe may be known by her total want of dreſs, without any other ſymbol. Her buſt is diſtinguiſhable by her ſupreme beauty, and is often adorned with pearls around the neck. We may here mention that CUPID ſometimes appears on the Syrian coins, in half-length, as the painters call it, and is known by his infancy and wings. 5 CYBELE has the turreted crown and lion; or is ſeen in a chariot drawn by lions. Her buſt is known by the firſt mentioned attribute. 6. CERES has the torches in her hands, with which ſhe is fabled to have gone in ſearch of her daughter Proſerpine. She has ſometimes two ſerpents by her, and is ſometimes drawn in a chariot by them. Her buſt is readily known by the wheaten garland, and is moſt common on coins of Sicily, an iſland celebrated for its fertility. Her daughter, Proſerpine, is alſo common with the name ΚΟΡΗ, or the *girl*. 7. ISIS, an Egyptian goddeſs, has the ſiſtrum in her hand, and a bud, or flower, on her head, ſymbolic of the eternal bloom of the inhabitants of heaven. The flower is ſaid to be that of the ἀβρότονον, or ſouthern-wood; but moſt probably it is a ſpecies of amaranth. 8. ASTARTE, a Sidonian goddeſs, appears on a globe, ſupported by a chariot of two wheels, and drawn by two horſes.

Mr. Pinkerton enumerates other deities that are leſs frequent on Greek coins; ſuch are Saturn with his ſcythe, or his buſt with a hook on thoſe of Heraclea:—Vulcan's head, with his tongs:—Adranus, a Sicilian god, with his dog:—Anubis of Egypt, with his dog's head:—Atis, in the Phrygian bonnet:—Caſtor and Pollux, with a ſtar on the head of each:—Dis, having an old face with diſhevelled hair and beard, and a hook:—Flora, crowned with flowers, on coins of Marſeilles:—Nemeſis, with a wheel:—and Pan with ſmall horns and brutes' ears. Some ſymbols are figurative of perſons or circumſtances: ſuch are vaſes, with ſprigs of plants iſſuing out of them, ſymbolic of ſolemn games:—the ſmall cheſt, or hamper, with a ſerpent leaping out of it, exhibiting the myſtic rites of Bacchus, coins with their image being called "Ciſtophori:"—the anchor, on Seleucian medals, aſcertaining their having been ſtruck at Antioch, where an anchor was found in digging the foundation of the city, though at a conſiderable diſtance from the ſea:—Apollo ſitting upon a ſingular ſeat, reſembling a hamper inverted, perhaps a tripod with a covering of network,

work, on different coins of the princes of Syria:—the bee, a mark of Aristeus, son of Apollo and Cyrene, much worshipped in the isles of the Adriatic and Ægean seas:—the laurel of Apollo:—ivy and grapes of Bacchus:—the poppy of Ceres and of Proserpine:—corn of Ceres:—owl and olive of Minerva:—dove of Venus:—and torch of Diana, Ceres, and Proserpine. The μυδρος, *mudrus*, or conic stone, was a token of the Sun, of Belus, and of Venus.

The most remarkable symbols of countries and cities on Greek coins are the flowers of the pomegranate for Rhodes:—owl for Athens:—pegasus for Corinth:—wolf's head for Argos:—bull's head for Bœotia:—minotaur's head, and the labyrinth, for Crete:—horse's head for Pharsalia:—lion for Marseilles:—tortoise for Peloponnesus:—sphinx for Scio:—three legs joined for Sicily:—and a horse for Thessaly. The badge of Byzantium was the crescent, which appeared early on the coins of Byzantium, with the legend ΒΥΖΑΝΤΙΝΗ ΣΩΤ.; the preserver of Byzantium. The occasion was this; when Philip of Macedon besieged Byzantium, and was proceeding to storm it in a cloudy night, the moon shone out, and discovered his approach, so that the inhabitants observed and repulsed him. The Turks, upon entering Constantinople, found this ancient badge in many places; and suspecting some magical power in it, assumed the symbol and its power to themselves; so that the crescent is now the chief Turkish ensign. (See CRESCENT.) The bull is very frequent on Greek coins, signifying, as Mr. Pinkerton suggests to be the most probable opinion, a river, on which the country or town was situated: accordingly, the river Achelous is called Βουκρανος, or bull-headed, by Sophocles in Trachin, v. 13: and Cephisus is said to have ταυρομορφον ομμα Κηφισου πατρος by Euripides, Ion. v. 1261. The Latin poets peak of the horns of rivers; thus Horace describes the Aufidus, "Sic tauriformis volvitur Aufidus." The bull was a token of fertility, but the horns seem to allude to the force of the stream, &c. See CORNUCOPIA.

On Roman coins the deities and personifications have not only attributes, but their names likewise in the legend of the medal, so that it is not necessary to dwell upon the explanation of them. Some, however, it may not be improper to mention. On the reverses of Roman colonial coins, easily distinguished by their rude fabric, and the name of the colony on them, commonly beginning with COL., when an ensign stands alone, and without any persons, it shews a colony drawn from one legion; but when the ensigns or banners appear in the like circumstances, they evince the colony to have been drawn from as many legions as there are ensigns. A bull on these coins often represents Apis as a symbol of strength and security: such was, probably, the bull upon the reverse of the common coin of India, with two stars over him, and the legend SECURITAS REIPUB. The caduceus marks peace and concord; the cornucopia, abundance; the pontifical hat, the priesthood. They all appear upon a reverse of Julius, and are symbols of the concord of the empire, and the plenty which attended his power: the last symbol merely denotes that Cæsar was Pontifex Maximus. The "parazonium" on Roman coins was a baton of command, and not a pointless dagger, as it has been described by many antiquaries. In later times the globe on an altar, with three stars, is supposed to typify the world preserved by the gods for the three sons of Constantine I. The fort and the gate are symbols of security. The altar is a well-known mark of piety: the tripod was a portable altar, used in temples for liquid offerings, as the altar was for solid sacrifice. A dolphin is sometimes twined among the legs of the tripod; the dolphin was sacred to Apollo, as appears from Servius on the 3d Æneid. The "lectisternia" also appear on medals. (See LECTISTERNIUM.) The instruments of sacrifice appear on many Roman coins: such are the "secespita," or oblong hatchet, or large knife for killing the victim:—the "aspersorium," a vessel for holy water, with which the priest sprinkled the assistants:—the "simpullum," or vessel for pouring wine on the sacrifice:—the "patina," or "patera," a dish for the fat, and other portions sacred to the gods:—and the "acerra," or little coffer for incense. The "lituus," or wand twisted round at the top, somewhat like the episcopal staff, is a badge of the augurship, as the "apex," or cap with strings, and terminating with a tuft, is of the pontificate. (See LITUUS.) The "thensa," or divine chariot, which carried the image of a deity in sacred processions, (improperly termed "carpentum" by some,) is a badge of consecration of an empress; as is also the peacock, which was the bird of Juno, the queen of heaven. These sometimes appear without the legend "consecratio," as the thensa on a coin struck under Tiberius for the consecration of Livia, the wife of Augustus, called Julia, S. P. Q. R. IULIÆ AUGUST.; and the peacock on that most rare gold coin of Julia, the daughter of Titus, the front of which has her bust, IULIA AUGUSTA, and the reverse a peacock, DIVI TITI FILIA. The eagle is the sign of consecration of an emperor.

The palm-tree, on both Greek and Roman coins, is symbolic of Phœnicia, where that tree flourished; as the silphium is of Cyrene, from the earliest times down to those of the Roman empire. Pinkerton's Essays, vol. i.

The titles are generally found upon the face of the medal. These are titles of honour, as Imperator, Cæsar, Augustus, given to all the Roman emperors after Octavianus; Dominus, first assumed by Aurelian, and used by his successors (see DOMINUS): other titles are ascribed to particular persons on account of their virtues, as Pius to Antoninus, assumed also by Commodus, with the addition of Felix; Pater Patriæ, first bestowed on Cicero for discovering and defeating the conspiracy of Cataline, and afterwards assumed by the emperors; Justus, the title of Pescennius; Beatissimus and Felicissimus of Dioclesian; Optimus and Clemens, decreed to Trajan by the senate; Maximus, assumed by Constantine; and Invictus, by Victorinus. In the lower empire, Stauracius first, and then Michael Ducas, and others, assumed the proud addition of ΒΑΣΙΛΕΥΣ, or king; which was followed by that of ΔΕΣΠΟΤΗΣ, or despot. Other titles are the names of offices; as COS. for consul, with a number annexed to it, signifying how many times the person had been thus elected: Tribunitia potestas, with the year of the tribuneship commonly expressed after the title, as TRIB. POT. X. or XVI. &c. The office of Pontifex maximus, expressed by P. M. was assumed by the emperors, and generally expressed among their titles, from Augustus to Constantine, by whom it was refused: it was re-assumed by Julian, and laid aside by Gratian. Julius Cæsar assumed the title of Dictator perpetuus; Claudius, that of Censor; and Domitian made himself Censor perpetuus.

The large early copper coins only bear ROMA in the reverse. Afterwards we find the names and titles of the Quæstor or Director of the public treasury, the Triumviri who managed the mint, the Prætor, the curule Edile, the Edile of the people, the Præfect of the city, the Pontifex Maximus, Augur, Quindecimvir sacris faciundis, Flamen Martialis and Quirinalis, Septemvir Epulonum, and latterly, Triumvir Reipublicæ constituendæ, and ad Frumentum emundum. Of the great magistrates out of Rome, who had moneyers with them, in order, from bullion and the spoil of the enemies, to coin money for paying the troops engaged in foreign service, we have the names and titles of Imperator, Proconsul, Proconful, Propraetor, Legatus, Legatus pro Praetore, Quaeftor, Proquaeftor, Legatus Claffis, Triumvir Coloniae deducendae, or reficiendis facris aedibus. All thefe titles appear on the reverfes of what are called confular coins; while the obverfe bears the head of a deity, generally without a legend. In time the magiftrates put the head of fome illuftrious anceftor on the coins, with his name; as Numa, Ancus Martius, Quirinus or Romulus, Brutus, Ahala; Caius Coelius Caldus, obverfe of Caldus III. vir, and the like. This led the way to Caefar, who firft put his own head on his coins, when made perpetual Dictator; with the legend of names and titles on the obverfe, and not on the reverfe as before. The infcription VOT. V. MVLT. X. VOT. X. MVLTIS XX. occurs on many reverfes of Roman medals, and moft commonly marked on a fhield, or within a crown of laurel. This Du Cange interprets to refer to the artifice of Auguftus, who pretended to lay down his power, and refume it for 10 years longer as at the requeft of the fenate. This term, he fays, was by fucceeding emperors fhortened to five; and folemn vows were entered into by their fubjects for their fafety to the end of that period; nay, that the double of that period might be allotted to their reign, again to be prolonged, on the wifhes of their people, to a future date. This infcription is alfo found upon coins of Crifpus, and other Caefars, or heirs of the empire; and it hence appears, that the honour of fuch folemnities was alfo conferred on them, who created Caefars. The "Vota Decennalia," as on coins of Pertinax and of Papianus, were only vows to perform the Decennalia, if the emperor fhould reign 10 years; whereas "Primi Decennales," or "Secundi Decennales," imply thefe games to have been actually performed; and the emperor to have reigned 10, or 20 years. On coins of Lucilla, Hadrian, Severus, Caracalla, and others, we find VOTA PVBLICA, with a facrifice; fhewing that the vows were undertaken, with that rite, as they were afterwards performed with folemn games and rejoicings. Coins of Conftantine II., and of Conftans, only bear SIC. X. SIC. XX. to exprefs the wifhes of the people, that, as the emperors had happily reigned 10 years, fo they might reign 20. There were alfo "Vota Quinquennalia" for the emperor reigning five years, and games called "Quinquennalia" performed when he had accomplifhed that period. From Aurelius Victor, in his life of Gordian III., it appears that Nero introduced this practice; which is mentioned by Tacitus, and by Lampridius in his life of Diadumenus. There were alfo "Vota Novi Anni," as appears from Spartian's life of Hadrian, and from Dio, l. 58; and there is a coin of Antoninus with S. P. Q. R. A. N. F. F. OPTIMO PRINCIPI, Senatus populufque Romanus annum novum fauftum felicem, &c. *i. e.* the fenate and people of Rome wifh a profperous and happy new year to the beft of princes. See LEGEND.

MEDALS, *Greek*, claim that place in a cabinet from their antiquity, which their workmanfhip might enfure to them, independently of that adventitious confideration. The invention of coinage, as we have elfewhere obferved, is afcribed by Herodotus to the people of Lydia, upwards of 1000 years before the Chriftian era. The abbé Barthelemy, cited by Mr. Pinkerton, arranges the following ftages of the progrefs of coinage. 1. Coins without any impreffion. 2. Thofe with a hollow indented mark or marks on one fide, and impreffion in relief on the other. This clafs, it is fuggefted, feems to extend from about the year 900 before our era, to about 700. 3. Such as have an indented fquare divided into fegments, with a fmall figure in one of the fegments, the reft being vacant; and impreffions on the obverfe, as ufual. Thefe may extend to the year 600 B.C. 4. Thofe which are ftruck hollow on the reverfe, while the obverfe is in relief commonly with the fame figure; which coins may be confidered as of equal age with thofe in the laft clafs. 5. Coins in which a fquare dye is ufed, either on one or both fides. Thefe were difcontinued about the year 420 B.C. 6. Complete coins both in point of obverfe and reverfe. Some of thefe occur in Sicily, where this art was carried to a perfection unknown in any other country, fo early as the time of Gelo, who began his reign in the year 491 B.C. Coins of moft remote antiquity, fays Froelich, quoted by Pinkerton, may be diftinguifhed by thefe infallible marks. 1. Their oval circumference, and globous fwelling fhape. 2. Antiquity of alphabet. 3. The characters being retrograde; or the firft divifion of the legend in the common ftyle, while the next is retrograde. 4 The indented fquare. 5 The fimple ftructure of the mintage. 6. Some of the very old coins are hollowed on the reverfe, with the image impreffed on the front. 7. The drefs, fymbols, &c. are often of the rudeft defign and execution. The coins of Pofidonia, Crotona, Sybaris, and two or three other cities, bear thefe marks of profound antiquity. Some Perfian pieces, with the archer upon one fide, and the hollow fquare upon the other; and feveral coins of the firft kings of Macedon, are examples. In the Britifh Mufeum, there is a medal of filver afcribed to Lefbos, of this defcription. In a fhort time the Greeks affumed great elegance; and it is obferved by Mr. Pinkerton, that innumerable of the medals of cities, which, from the character, we muft judge to be of the higheft antiquity, have a furprifing ftrength, beauty, and relief, in their impreffions. About the time of Alexander the Great, the art feems to have attained to its very higheft perfection. Of the Greek medals, thofe of cities are the moft ancient. The civic medals are generally ftamped on the obverfe, with the head of the genius of the city, or fome favourite deity; while the reverfe often prefents fome fymbol ufed by the city, at the time when the piece was ftruck. The legend contains the initials, monogram, or whole characters of the name of the city. Some connoiffeurs prefer the regal coins of Greece; others the civic. The former intereft by their portraits; the latter by their variety. The former are perhaps more important to ancient hiftory; and the latter to ancient geography. The civic coins are interefting, as they prefent us with a view of the cuftoms, religion, &c. of ancient cities; they likewife afford a kind of political barometer of the wealth and power of each city and country. *E.G.* The numerous and beautiful gold coins of Cyrene, a country, from its remote fituation, little known in hiftory, afford fufficient proofs of its great power and wealth. The fmall civic coins of gold, electrum, and filver, ftruck in Afia Minor, are perhaps fome of the earlieft; though if we judge from workmanfhip, thefe coins are fo exquifite, that the coins of Greece, from their rudenefs, feem to claim priority of era; and Mr. Pinkerton fuggefts, that it is dubious whether Greece or Lydia firft invented coinage.

The Greek monarchic coins are often of the fame conftruction with the civic; only that they bear the name of the prince on the reverfe; many fuch occur with the buft of fome deity in front, for one which prefents the image of the prince. The moft ancient feries is that of Macedon, commencing, as we have obferved already, with Alexander I., who began his reign 501 years before our era. With Philip, the Macedonian coins begin to be beautiful. Thofe of Alexander the Great are wonderful. The head of Minerva on his gold, affords a variety of exquifite faces; and the coins of Alexander and his father, exceed all that were ever executed, except thofe of Sicily, Graecia Magna, and the ancient ones of Afia Minor. Sicilian coins are famous for

for workmanſhip, even from Gelo's time. The coins of the Syrian kings, ſucceſſors of Alexander, almoſt equal his in beauty. Thoſe of Antiochus VI. are peculiarly exquiſite, both for the beauty of the coin and that of the king. The Egyptian Ptolemies have fine relief, but do not equal the Syrian in delicacy and finiſh. The family coin of Ptolemy Philadelphus, before mentioned in this article, is extremely fine and intereſting. There is a coin of Alexander, ſon of Neoptolemus, king of Epirus, with a head of Jupiter Dodonæus, crowned with oak, of miraculous workmanſhip, and thought to be done in Magna Græcia, when he came to aſſiſt the Tarentines. This has been engraven by Bartolozzi. Even the earlier Parthian coins of the Arſacidæ are worthy of the Grecian workmen, whoſe they are, as is evident from the Greek legends impreſt on them, in many of which theſe monarchs aſſume the title of ΦΙΛΕΛΛΗΝΟΣ, or lover of the Greeks. It is to the Greek coins that were ſtruck before the Roman empire ſwallowed up the Greek cities and ſovereignties, that the high praiſe beſtowed by good judges upon the Greek mint, muſt be chiefly confined; for the Grecian imperial medals are not equal to the former, though they do not always yield to the Roman.

In the ſeries of Grecian imperial coins, we meet with very uncommon portraits and reverſes. In attention to the fair ſex, the people of Mitylene, the chief city of Leſbos, and the birth-place of Sappho, have peculiarly diſtinguiſhed themſelves. Thoſe Greek coins of cities, which have the head of an emperor or empreſs, are called Imperial Greek coins; but thoſe which have no ſuch impreſſions are claſſed with Grecian civic coins, though ſtruck under the Roman power. Of imperial Greek coins none occur in gold; but there are thoſe of ſilver of Antioch, Tyre, Sidon, Tarſus, Berytus, Cæſarea, and one or two other trading cities in that opulent and commercial region. Thoſe of Antioch preſent, now and then, the genius of the city ſitting, with the river Orontes flowing beneath her feet, as on coins of Syrian monarchs. Syrian ſilver coins ſometimes bear the club of Hercules, the founder, or the famous Tyrian ſhell-fiſh, whence the Tyrian purple, our crimſon, was derived. Sidon gives the car of Aſtarte, or a head of the goddeſs: Tarſus has ſometimes only a monogram, expreſſing the name of the city. Cæſarea, in Cappadocia, abounds in ſilver of various ſizes; and ſilver coins of Lycia appear to be of good work, and good metal; the reverſe having two harps and an owl ſitting on them. Silver coins of Gelon, a town of Sarmatia, much reſemble the Syrian; and have the ΔΗΜΑΡΧ. ΕΞΟΥΣΙΑΣ, with an eagle holding a ſtag's foot. The Greek imperial braſs coins are ſo abundant, that it is hardly neceſſary to ſpecify any of them. Thoſe of Antioch, generally with a Latin legend on the obverſe, and Greek on the reverſe, are ſo numerous as to furniſh a ſeries of almoſt all the emperors; being apparently ſtruck for the purpoſe of paying the forces in the Eaſt. Thoſe of Ceretapa, in Phrygia, are diſtinguiſhed by their good workmanſhip, as alſo are thoſe of Bithynia and Phrygia. On thoſe of Tarſus are curious views of objects, almoſt in perſpective; and there is a ſingular coin of Gangra in Paphlagonia, with a view of two caſtles and houſes between them. This is in the late Dr. Hunter's collection. The coins of Egypt under the Roman emperors, being marked with Greek legends, range with the Greek imperial medals; they are remarkable for thickneſs, and baſeneſs of metal. Thoſe of the ſilver ſeries are at firſt about the ſize of an half crown, but three times as thick; after the time of Commodus, they declined both in ſize and baſeneſs, and became reduced to the ſize nearly of a ſixpence, and the metal is only bad braſs waſhed with ſilver. The ſilver coins of Egypt are not ſo well done from Auguſtus to Nero, as afterwards. From Nero to Commodus, they are often admirable, and of a ſtyle of workmanſhip that can be called neither Greek nor Roman. The reverſes are extremely various and ſingular, exhibiting the capricious religion and manners of the people. From Commodus the Egyptian ſilver gradually declines till the reign of Conſtantius I., when it ends. The ſeries conſiſts of 1000 coins, or more. Many ſcarce portraits of emperors and of empreſſes decorate the ſeries. The Egyptian braſs coins of the Roman period claim notice. Until Veſpaſian there are only two ſizes, equal to the ſecond and third Roman braſs. Veſpaſian indulged the Egyptians with the privilege of iſſuing large braſs, as uſed in Rome itſelf. All the Egyptian Othos, the moſt common coins of that prince in braſs, are of the ſecond ſize; and bear for reverſe an head of Iſis, or Serapis, with L.A. or year firſt. Some have names of towns, and in Dr. Hunter's cabinet, there is a fine one of Cebennutus in firſt braſs, of Domitian, who appears decorated with a wheaten, as Gallienus does in Roman gold. On the braſs coins of Egypt, a female figure, with part of a ſhip in her hand, and the Pharos behind, is very common, probably expreſſive of Alexandria. One of Antoninus Pius, in third braſs, preſents to us Iſis ſitting on the flower of the lotus. With this emperor very fine work begins in the Egyptian braſs. The 12 coins of this prince, with the 12 ſigns are very curious, and publiſhed by Barthelemy, Mem. de l'Acad. xli. The laſt braſs coins of Egypt, are of Marcia Otacilia Severa, wife of Philip the Elder, A.D. 244. The genuine braſs coins of Egypt are thinner than the ſilver, and of a diſtinct fabric.

MEDALS, *Roman.* It was in the reign of Servius Tullus that the firſt Roman coins appeared, which were large pieces of braſs, rudely impreſſed, only on one ſide, with the figure of an ox, a ram, or ſome other animal, whence, it is ſaid, money was denominated "pecunia." Theſe ſymbols were derived from the Tyrrheni or Etruſcans, a people of Italy, originally Lydians. In proceſs of time the impreſſion of the *as* was changed to that of a buſt of Janus, upon the front, and the prow of a ſhip on the reverſe; and for more general uſe, pieces of inferior weight and value were coined. See As and MONEY.

The Roman coins, conſidered as medals in a cabinet, comprehend the two grand diviſions of *conſular* and *imperial* coins. The Roman *conſular* coins ſeldom or never bore the names or titles of conſuls till towards the cloſe; nevertheleſs they are not improperly called conſular, becauſe they were ſtruck in the conſular times of Rome. They are alſo called coins of families; and are always arranged alphabetically in families, according to the names which appear on them. The braſs conſular coins are rather unintereſting; as they conſiſt chiefly of large unwieldy pieces, with types of inſipid ſimilarity. Few of them have any imagery or ſymbol. The large ancient pieces are generally kept in boxes apart, by thoſe who are verſed in them. (See As.) The next coinage to that of braſs was that of ſilver, which took place, according to Pliny, in the 485th year of Rome, that is, about 300 years after the firſt braſs coinage, and 266 years B.C. The denarius was the firſt and the laſt form which it aſſumed, for the other ſizes are ſo ſcarce, that it is certain very few were ſtruck. (See DENARIUS.) Until the age of Julius no portrait of a living perſonage appears upon any Roman medal; Cæſar was indeed the firſt who aſſumed that high honour, and a competent judge aſſerts, that the plan of engraving on coins the names of great men and magiſtrates was only introduced about the time of Marius and Sylla. The reverſes of ſome few conſular medals are fraught with much erudition and curious matter. On a coin of the family of Æmilia, we have this legend, M. LEPIDUS PONT. MAX. TVTOR REGIS, cus, and Lepidus appearing in the dreſs of a conſul, and putting the crown on the head of young Ptolemy, whom his father had left to the tutorage of the Roman people. On the obverſe is the turreted head of the city of Alexandria in Egypt, with ALEXANDRIA. In the ſame family there is a medal, with a youth on horſeback, carrying a trophy, with this legend, M. LEPIDUS ANNORUM XV. PRÆTEXTATUS HOSTEM OCCIDIT CIVEM SERVAVIT. Again, L. Æmilius Paulus, on a coin of the ſame family, appears dedicating a trophy for his victory over Perſeus, who, with his two children, ſtand by, their hands being tied behind their backs. Portraits of Bacchus, Jugurtha, the laſt Philip of Macedon, the 1ſt and 2d Brutus, Metellus, Marcellus, Regulus, Sylla, Pompey, Caldus, and others appear on conſular coins. Rome and Italy are perſonified; Victory crowns Rome; with other ſpecimens of that fine perſonification afterward diſplayed on the imperial coins. Gold was firſt coined at Rome, 62 years after the application of the mint to ſilver. The general gold coin is the *Aureus*, which ſee. The conſular coins, whoſe number is eſtimated at 200 in braſs, and 2000 in ſilver, extend not to above 100 in gold, of which moſt are curious. The beautiful Pompey with his ſons on the reverſe, and the Brutus with his brother Lucius, commonly claſſed with imperial coins, ſhould rank with the conſular. Moſt of the gold conſular coins are of great beauty and high value. Of conſular medals father Joubert reckons about fifty or ſixty of gold; two hundred and fifty of copper; and near a thouſand of ſilver. Goltzius has deſcribed them in a chronological order, according to the Faſti Conſulares; and Urſinus has diſpoſed them genealogically, according to the order of the Roman families. M. Patin has collected an entire ſeries of them, in the ſame order with Urſinus; and only computes one thouſand and thirty-ſeven conſulars, which relate to one hundred and ſeventy-eight Roman families. M. Vaillant, and M. Morel, have alſo publiſhed on the ſame ſubject. See the ſequel of this article. The Roman *imperial* coins claim our attention from a variety of conſiderations; and more particularly from the extent of the Roman empire, and from our own connection with it. The Roman coins may be called thoſe of the emperors of Europe, and intereſt us like thoſe of our own country. Some have diſtinguiſhed the imperial coins into thoſe of the *upper* and *lower empire;* the upper empire commenced under Julius Cæſar, and ended about the year of Jeſus Chriſt two hundred and ſixty; the lower empire comprehends near one thouſand two hundred years; *viz.* till the taking of Conſtantinople. It is the cuſtom, however, to account all the imperial medals, till the time of the Palæologi, among the antique; and yet we have no imperial medals of any conſiderable beauty, later than the time of Heraclius, who died in 641.

After the time of Phocas and Heraclius, Italy became a prey to the Barbarians; ſo that the monuments we have remaining of thoſe two emperors, finiſh the ſet, or ſeries of imperial medals. To theſe are added the medals of the lower empire, and of the Greek emperors; whereof a ſeries may be made as low as our times, taking in the modern ones. M. Patin has made an ample collection of the imperial medals, till the time of Heraclius.

The Gothic medals make part of the imperial ones; they are ſo called, as having been ſtruck in the times of the Goths, and in the declenſion of the empire, and ſavouring of the ignorance and barbarity of the age.

Cæſar, who begins the imperial ſeries, was conqueror of Gaul; Claudius of Britain. As to the braſs coinage it has been already obſerved, that at the time of Marius and Sylla, about 50 years before that of Cæſar, ſome elegance and variety commence in the Roman coinage. In the times of Julius Cæſar this elegance was carried to a great height. In the family of Marcia, there is a beautiful As, with the heads of Numa and Ancus; the reverſe Victory in a porch, and the prow at her feet. Indeed it is only in the half ounce As that variety can be found. Sylla, as we are informed by Cicero, and by gold coins remaining, introduced great confuſion into the coinage; and it is not improbable, that the braſs had its ſhare, by alteration of ſizes and types. The imperial braſs is of three ſizes, *large*, *middle*, and *ſmall*. The *large* braſs form a ſeries of ſurpriſing beauty and vaſt expence. In this ſeries the various colours of the patina have the fineſt effect; and the great ſize of the portraits and figures conſpires to render it the moſt important of all the Roman coinage. It even exceeds the gold in value.

The ſeries of the *middle* braſs exceeds the former in number; but doth not preſent ſuch elegance of work, or of types. Many coins are common in ſecond braſs, which are rare in firſt; but very few examples occur to the contrary. Hence this ſeries yields much to the former in price, as well as in dignity. However, many rare and curious coins occur in this ſeries. There is a Tiberius, with this inſcription on the reverſe, TRIB. POT. XXXVIII. A Gallienus, obverſe with his head, bearing a laurel over a turret on his forehead, GENIUS P. R. reverſe with this inſcription ANT. URB. S. C. Coins of Fauſtina the elder are common in this ſize; but thoſe without DIVA are very ſcarce, and always bear ANTONINI PII AUG.; a circumſtance, which ſeems to indicate, that moſt of theſe coins were ſtruck by her good huſband, after her death. In the firſt and ſecond braſs there are many coins, which particularly intereſt us as Britons, becauſe they relate to the hiſtory of this iſland. Such are the triumphal arch of Claudius, inſcribed DE BRITANN., alſo occurring in gold and ſilver; the ADVENTUI AUG. BRITANNIÆ, and EXERC. BRITANNICUS of Hadrian; the coins of Antoninus Pius, Commodus, Severus, with a victory, VICTORIA BRITAN., but eſpecially thoſe perſonifying the country *Britannia*.

The *ſmall* braſs ſeries abounds with curious coins. Till the times of Valerian and Gallienus, they are generally ſcarce; but afterward extremely common. In the former period portraits of the emperors are rare in ſmall braſs, but in the latter many are found which occur in no other ſeries, as moſt of the uſurpers, Zenobia, Vaballathus, and many others. All real braſs coins have the S. C. till the time of Gallienus; as the ſenate alone had the power of ſtriking braſs, while the emperor himſelf had that of gold and ſilver. When the S. C. therefore is wanting, the coin was certainly once plated. With Pertinax A.D. 192, there is a temporary ceſſation in the ſmall braſs; nor after him do any princes occur in that ſeries till Valerian, A.D. 254, excepting Trajanus Decius A.D. 250, only. After Valerian, the ſeries is continuous, and common. The braſs coinage declined in ſize from the time of Severus, and Trajanus Decius in vain attempted to reſtore it; and Valerian and Gallienus were forced to iſſue denarii ærei of billon, and ſmall aſſaria. The ſeries of large and of middle braſs are of two fixed and known ſizes; the former about that of our crown, and the latter of our half-crown, till after Severus they gradually leſſen. But the ſmall braſs takes in all the parts of the As, and every braſs coin not larger than our ſhilling in ſize belongs to this ſeries. Our limits will not allow our enumerating the coins of this ſeries, but we refer to Pinkerton's Eſſ. vol. i. p. 272, &c. The ſeries in ſmall braſs extends from the beginning to the cloſe of the Roman empire, nay, far into the Byzantine, cloſing with Conſtantine Pogonatus, A.D. 670.

The ſilver imperial coins are very numerous and various. This ſeries is as complete as any, and of far cheaper purchaſe, very few emperors being ſcarce in ſilver. Moſt types

even

even of the large brafs and gold are found in the filver, which thus unites the advantages of all metals. Sometimes the filver and gold coins, as being of one fize, are ftruck from the fame dye, as the young Nero, reverfe a votive fhield EQUEST. ORDO PRINC. JUVENT. and others. One of the rareft filver coins is that of Gneius Pompey, fon of the great Pompey, in Dr. Hunter's collection. It is fuppofed to have been ftruck in Spain, before the battle of Munda, foon after which he was flain.

The imperial gold forms a feries of wonderful beauty and perfection; but it is only attainable by men of princely fortunes. In thefe the workmanfhip is carried to the greateft height; and the richnefs of the metal furpaffed by that of the types. As gold refufes ruft, the coins are generally in the fame ftate as they came from the mint. The number of Roman gold imperial coins may amount to 5000; the filver to 10,000; and the brafs to 30,000. The whole of the different ancient coins may amount to about 80,000; but the calculation cannot be very accurate.

Before we clofe this account of Roman medals, the *colonial* ought to be mentioned. As Roman colonies were fettled in various parts of the empire, their coins have fometimes Greek, fometimes even Punic legends; though generally that on one fide of fuch is Latin. But thofe with Latin legends only are far more numerous. Some of thefe coins are elegant, though moft are rude and uninterefting. The colonial coins only occur in brafs; thofe in firft brafs are very rare till the time of Severus. They begin with Julius and Antony. The Spanifh colonial coins ceafe with Caligula, who took away this privilege from Spain. The colonial coins of Corinth are the moft various and beautiful; prefenting triumphal arches, temples, gates, ftatues, baths, and figures of gods and goddeffes. Other remarkable colonial coins are of Emerita, of Illice, of Tarraco. The coins of Caffandria in Macedon are generally fmall brafs, with the head of Jupiter Ammon on the reverfe, and furnifh that feries with many fine heads of emperors, with Latin legends, from Claudius to Severus, but always with the fame reverfe. Many fcarce portraits are found in colonial coins of that fize; as the two Agrippinas, Agrippa, Cæfar, Drufus Cæfar, Octavia Neronis, Cæfonia, Meffalina, and others. It is remarkable, that while Spain had perhaps 50 colonies, Camalodunum is the only one in Britain of which there are coins. There is one of Claudius, reverfe a team of oxen, COL. CAMALODON. AUG. The fmalleft imperial filver alone are quinarii, the gold being femiffes and trientes, and the brafs at firft fmall parts of the As, and latterly only the half affarion. Thefe, inftead of being denominated quinarii, might, more properly, be called "minimi;" as including the very fmalleft coins of all metals and denominations. The Roman coins have had a moft extenfive fpread; fome of them have been found in the Orkneys; and they have likewife been found in numbers in the moft remote parts of Europe, Afia, and Africa, at that time difcovered.

As for the medals of other ancient nations, befides Greece and Rome, fome notice fhould be taken of them; premifing that by *ancient* coins, all preceding the ninth century, or age of Charlemagne, are meant; and all pofterior to that period are *modern*. No coins are found which can even be imagined to belong to Affyrian, Median, or Babylonian kings. The oldeft coins found in their empire are palpably Perfian and fimilar to the Greek. The Phœnicians do not appear to have coined money, till after the Greeks had fet the example. No Phœnicians were ever found of much antiquity; and not one, without both obverfe and reverfe, nor are any of them older than about 400 years before our era. Weight alone was ufed in the famous cities of Tyre and Sidon, as we learn from fcripture; and in Egypt coinage was unknown, not a coin with a hieroglyphic being found; and in the mouths of the mummies there are only thin broad pieces of unftamped gold, to pay Charon's fare. India appears to have no claim to an early ufe of coinage. No Indian or Chinefe coins exift till within a late period; and thofe of both countries are fo rude as hardly to deferve being collected. Upon the whole the Lydian coins feem to be the moft ancient in Afia. Next to thefe are the Perfian, well known from the archer on them, and from Mithras the Perfian deity, the drefs of the princes and other marks. None of thefe coins can be older than 570 years before our era, when the Perfian empire began. The famous darics were iffued by Darius Hyftafpes, who began to reign 518 or 521 years B.C. See DARIC.

Of Perfian coins, there is a fecond feries, that of the Saffanidæ, beginning about 210, when Artaxerxes overturned the Parthian monarchy. The Parthian coins have all Greek legends, but thofe later Perfian bear only Perfian characters: they are large and thin, with the king's buft on one fide, and the altar of Mithras on the other, generally with a human figure on each fide. The letters on Perfian coins feem to partake of the ancient Greek, Gothic, and Alanic. The later Perfian coins extend to the year 636, when Perfia was conquered by the Arabian caliphs.

The Hebrew fhekels are of filver, and originally didrachms, but, after the Maccabees, about the value of the Greek tetradrachm; and the brafs coins, with the Samaritan characters, are moft of them later than the Chriftian era, and generally the fabrications of modern Jews. F. Souciet has a differtation on the Hebrew medals, commonly called Samaritan medals, in which he diftinguifhes between the genuine and the fpurious: and fhews, that they are true Hebrew coins, ftruck by the Jews, on the model of the ancients; and that they were current before the Babylonifh captivity. The fame impreffion of a fprig on one fide, and a vafe upon the other, runs through all the coins of this nation. The Phœnician coins are of Phœnicia, and the Punic of Carthage; and they are rendered interefting by the ancient civilization and great power of the Phœnicians and Carthaginians. The alphabets, which are nearly allied, have been illuftrated by their relation to the Syriac, Chaldaic, and Hebrew. The fame may be faid of the Palmyrene coins and infcriptions. (See PALMYRA.) The Etrufcan coins are infcribed with the Etrufcan character, which is fatisfactorily explained by its connection with the Pelafgic, or oldeft Greek and Latin. The Spanifh coins are infcribed with two or three different alphabets allied to the old Greek, or to the Punic. The ancient coins of Spain are numerous, and evidently not all ftruck by the Punic colonies, for the legends are in different characters. The ancient coins of Gaul are alfo numerous, and many of them in bafe gold, but unhappily the moft ancient have no legends at all.

In fpeaking of the coins of Britain, Cæfar fays of the natives, "they make ufe of brafs inftead of gold coin, or iron rings reduced to a certain weight inftead of (our brafs) coins." Mr. Pinkerton underftands his meaning to be, that our anceftors ufed brafs, apparently coined, as a fuperior metal, in like manner as more advanced nations ufed gold: and that *pro nummis*, inftead of the brafs coinage of Rome, (*nummus* being a peculiar name of the brafs feftertius,) they ufed iron rings, examined and reduced to a certain weight. Rude coins of copper, much mingled with tin, are frequently found in England, and may perhaps (as Pinkerton intimates) be the copper coins ufed by our anceftors; for Cæfar's expreffion merely infers, that their copper was in in the form of coins. These pieces are of the size of a didrachm, the common form of the "nummus aureus" among the ancients. We have many coins of Cunobelin, who was king of the Trinobantes, and educated, as it has been said, in the court of Augustus. He is mentioned by Suetonius and Dio. These coins of Cunobelin are the only ones apparently British. Most of them yet found have CVNO on one side, with an ear of wheat, a horse, a kind of head of Janus, or some such symbol, and often CAMV, thought to be the initials of Camudolanum, on the other side, with a boar and tree, and a variety of other badges. They have likewise frequently the word TASCIA upon them, which has not yet been satisfactorily explained; but it has absurdly, as Mr. Pinkerton conceives, been thought to be the name of the Moneyer, as the putting of the name of the Moneyer on coins was a late practice, unknown till the sixth century, and gradually introduced a century after the Roman mints had ceased in Europe, with the empire, and when private persons contracted with the kings for the little mints, and put their names to identify the mintage. In old German *tasg* is a purse: and the figure thought to be the mock moneyer *Tascio* is Vulcan making a helmet. All the kings of France down to Charlemagne range in this division. Liuva I. who began his reign in the 567th year of our era, and the other kings of the West Goths in Spain, appear upon their coins encircled with Roman characters. Other Gothic kings, who reigned in Italy and other countries, after the fall of the Roman empire in the West, likewise use the Roman language in their coinage. They most commonly occur in the size of medals termed small brass. Many coins also occur with legends, which, though meant for Latin characters, and in imitation of Latin coins, are so perverted as to be illegible. Such are in general termed *Barbarous* medals. Pinkerton's Ess. vol. i.

MEDALS, *Conservation of*, is a matter among medallists of peculiar importance. When a medal is in the least defaced in figures, or in legend, the true judge will reject it, hardly excepting even the rarest coins. Nothing contributes so much to the conservation of brass or copper coins as that fine rust, sometimes called "ærugo," appearing like varnish, which their lying in a particular soil occasions. Gold admits no rust but iron mold, when lying in a soil impregnated with iron. Silver takes many kinds; but chiefly green and red, which yield to vinegar. In gold and silver the rust is prejudicial, and ought to be removed; whereas in brass and copper it is preservative and ornamental; a circumstance remarked by the ancients, as the "pocula adorandæ rubiginis" of Juvenal may prove, and that exquisite Greek phrase, which terms "patina" χαλκου ανθος, the flower of brass. "This fine rust," says Pinkerton, "which is indeed a natural varnish not imitable by any effort of human art, is sometimes a delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze, and so highly prized; and sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour, or pale yellow: which last is exquisite, and shews the impression to as much advantage, as paper of cream colour, used in all great foreign presses, does copper-plates and printing. The Neapolitan patina is of a light green; and when free from excrescence or blemish, is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of deeper green is found; and it is sometimes spotted with the red or bronze shade, which gives it quite the appearance of the East Indian stone called blood-stone. These rusts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing at the same time not the most minute particle of the impression of the coin." Medals are subject to various blemishes. Sometimes the letters are displaced, as is commonly the case in those of Claudius Gothicus; sometimes the coins, for want of being well fixed in the dye, so as to have slipped at every stroke of the hammer, present a double or treble image. Of these last many are found, in which the portrait is deranged, while the reverse is distinct, and others have the portrait perfectly well struck, while the reverse confuses the eye by its double or triple contours. Ancient coins are subject to another blemish, which rather recommends them to the curious than otherwise. It is when, after having struck a coin, the workmen, through forgetfulness, put another into the dye, without withdrawing the first. Hence, the portrait of the other piece being commonly upward, and in the upper part of the dye, the second coin is impressed with it by the dye, and at the same time made hollow on the other side with the form of the portrait already stamped on the former medal. Some coins are found with a small stamp impressed on a part of them, bearing sometimes a minute head, or some letters, as AVG. or N. PROB. or the like. Such are called "countermarked" by medallists; and being very rare are the more valued, so that such must not be rejected or blemished. These countermarks are thought to infer, that an alteration had been made in the value of the coin; as was the case with the countermarked coins of Henry VIII. and of Mary of Scotland in modern times. Other coins are found with holes pierced through them; and sometimes with a small ring fastened. Such were worn as ornaments of the head, neck, and wrist; either by the ancients themselves, as bearing images of favourite deities, or in modern times, when the Greek girls thus decorate their persons. Coins of genuine antiquity are often found split on the edges, or even in the middle, by the force of the hammer. This, so far from being regarded as a fault, is looked upon as a great merit by the collector; being considered as a proof that the coin is undoubtedly of ancient fabric. Silver coins often acquire a particular yellow tarnish, giving them the appearance of having been gilt; but it is merely owing to their being deposited in a soil, whence a peculiar vapour arises, or some similar circumstance. Mr. Pinkerton has given the following hints concerning the method of cleansing coins from any prejudicial rust. "Gold is cleaned by any acid: spirit of nitre eats every thing but gold, and is therefore an effectual cleanser of that metal. The green, blue, or red rust, may be removed from silver, by steeping in vinegar for a day or two: but a more effectual way is to boil with a mixture of three parts tartar, and one sea-salt in water. On gold and silver the rust is always in spots, and never forms an entire incrustation, as on brass and copper; whence it is always regarded as a blemish in the former metals. Very different is the case with brass and copper, and they are never to be cleansed, for coins in these metals would be disesteemed if rendered bright, and would be full of small holes, occasioned by the rust. But sometimes brass and copper coins are found wholly obscured with rust; and one of the best ways of clearing them, if used by a skilful hand, is a graver. Another way is to boil in water for twenty-four hours, with three parts tartar, and one part alum, (not sea-salt as in silver,) and then cleanse with bran. But it is a dangerous business to cleanse coins; and ought always to be committed to a skilful hand, or let alone."

See

See Joubert des Medial. sect. viii. Act. Erud. Lipf. 1694, p. 226.

Some authors imagine, that the ancient medals were ufed for money. M. Patin has a chapter exprefs to prove, that they had all a fixed regular price in payments, not excepting even the medallions. F. Joubert is of the fame opinion. Others, on the contrary, maintain, that we have no real money of the ancients; and that the medals we now have, never had any courfe as coins. Between thefe two extremes there is a medium, which appears by much more reafonable than either of them. See MONEY.

MEDALS *and Coins, Modern,* as contradiftinguifhed from thofe that are denominated *ancient*, comprehend, as we have already obferved, all thofe that have been ftruck fince the time of Charlemagne, or the commencement of the 9th century. Mr. Pinkerton, of whofe valuable "Effay on Medals" we have been allowed to avail ourfelves in the compilation of this article, has divided the fubject into "Modern Coins" and "Modern Medals." He obferves, that down to the revival of literature in the beginning of the 16th century, modern coins are fo very rude, that curiofity fuggefts the fole inducement to examine them. Without dates or epochs they cannot ferve one purpofe of utility. The very portraits found on them are fo uncouth, that the human face divine is hardly difcernible. The reverfes always bear a moft beautiful crofs garnifhed with pellets, or a difh of fome fuch exquifite flavour. Yet fuch is the luft of curiofity, of completing a feries, or of felf-love indulged in the extreme, by poffeffing a bauble which nobody elfe does, that ten or twenty guineas are often given for one of thefe pretty little things. To us, however, as Britons, the ftudy of thefe coins may be regarded as peculiarly interefting, as they furnifh monuments illuftrating, or relating to, perfons or actions, in the glory of which the common paffion of national vanity warmly interefts our affections. Thus, the noble of Edward III., on which he appears in a fhip, as afferting the Britifh dominion of the ocean, would, though uncouth in the execution, which it by no means is, juftly command our higheft regard and attention; and doubtlefs any patriot, or any Briton, would, even in thefe days, place moft juftly a higher value upon this coin, than upon the moft perfect medal which Grecian fkill has produced. Upon the fame principle, the coins of Edward the Black Prince are interefting; and, indeed, the whole Englifh feries muft be interefting to every one who feels himfelf particularly concerned in Englifh hiftory.

In this place modern coins are regarded merely as they appear in a cabinet; but for their commercial value, we refer to other articles, fuch as COIN, MONEY, &c. Beginning with the moft eaftern part of Afia, the coins of *Japan* firft attract notice. Thefe are thin plates of gold and filver, large and oval, ftamped with little ornaments and characters. The only coins of *China* are in copper, about the fize of a farthing, with a fquare hole through the middle, in order to their being ftrung for the convenience of enumeration or of carriage. They bear an infcription in Chinefe characters, expreffing the year of the prince's reign, without his name, diftinguifhed as the "*Happy* year," "*The Illuftrious* year," and the like. It is faid, that Canghi, the emperor, who died in 1722, after a reign of 61 years, formed a complete cabinet of Chinefe coins, and appointed a Mandarin to keep it. The coins of *Tartary*, which are pofterior to Genghis-Khan, are rude, and generally prefent only infcriptions. In *Thibet*, *Pegu*, and *Siam*, the coins are various; but evidently of late origin, and generally bearing infcriptions on both fides. Such alfo are thofe of many fmaller ftates in Eaftern Afia. In the country fo celebrated anciently by the name of *India* the Mahometan faith is predominant, as it is in moft countries of Weftern Afia. The precept of Mahomet, which forbids the reprefentation of any living creature, has had a pernicious effect upon the arts. It is doubtful whether or not any Indian coins exift before the time of the Moguls, or the 13th century. Some old coins have been found near Calcutta, of gold, filver, copper, and tin, all mingled in one bafe mixed metal. On one fide they bear a warrior with a fword, and on the other an Indian female idol. The later coins of India are well known, fuch as the pagoda, rupee, and cafh, the moft common copper, whence our word. All thefe coins are very thick, like the old Egyptian. On one remarkable fet of rupees, are prefented the twelve figns, a lion on one of them, a bull on another, &c. &c. The Portuguefe, Englifh, French, and Dutch, fometimes ftruck coins in their fettlements with Perfian infcriptions on one fide and Latin on the other. Rupees and cafh are known of Elizabeth, of Charles II., of the year 1730, and of other periods. The coins of *Perfia* have continued on the Arabian model, even after the Arabian caliphs loft their dominion in that country, and bear on both fides pious infcriptions from the Koran. The Perfian copper, however, has the fun and lion, the arms of Perfia, on one fide. Of Mannus, and fome other petty kings in *Arabia,* we have coin during the imperial period of Rome. The brafs coins of Haroun Al Rafchid, the Charlemagne of Afia, and his contemporary, and of other powerful princes who refided at Bagdad, have an Arabic infcription on the reverfe; the obverfe is a mere tranfcript of any old Greek or Roman coin that fell in the way of the Moneyer. The gold and filver coins have many infcriptions. The later Arabian coins, which are filver, bear the name and titles of the prince on one fide, and fome fentence from the Koran, or the like, upon the other. The more modern are in the fhape of a fifh-hook, with Arabic infcriptions. The coins of *Turkey* refemble thofe of Perfia and Arabia, having merely infcriptions on both fides. The coins of Africa, comprehending Morocco, Fez, Tripoli, Algiers, &c. are upon the Mahometan plan of mere infcriptions. Paffing over Abyffinia, and the interior kingdoms of Africa, as little known, and the civilized empires of America, Mexico on the N., and Peru on the S., where coinage was not practifed, we fhall proceed to the coins of Europe. In *Italy*, when the Roman empire in the weft ceafed with Romulus, in the year 476, the Gothic kings ftruck coins till Teias, the laft of them, was conquered in 552 by Narfes, the general of Juftinian. Then the exarchs of Ravenna, viceroys for the Byzantine emperors, iffued copper with FELIX RAVENNA, &c.; but the gold and filver of the Greek emperors fufficed for Italy. After Charlemagne, about the year 780, made a great revolution in Italy, there are coins of him ftruck in Rome and Milan. In the next century the modern coins of Italy begin with the filver pennies of various ftates. The papal coins originate with Hadrian I. 772—795, to whom Charlemagne gave leave to coin money. The filver pennies continued till a late period, with the name of the pope on the one fide, and SCUS PETRUS on the other. On thefe coins there are rude portraits of fome of the popes. Afterwards, when the pope ceafed to have power in Rome, from Pafchal II. till Benedict XI. in 1303, there are pennies of the Roman fenate and people, bearing on one fide Peter, ROMAN. PRINCIPE, on the other Paul, SENAT. POPUL. Q. R. In the middle ages the chief bifhops of Italy, France, and England, ftruck coins, as well as the pope. The firft gold coin is of John XXII. 1316. The coins of Alexander VI., Julius II., and Leo X. are remarkable for elegance.

elegance. The coins of *Milan* begin with Charlemagne, a croſs, reverſe the monogram of Carolus, with MEDIOL., and they are found of the other emperors to the 13th century. Theſe coins are of ſilver. In *Naples* there are coins of duke Sergius, 840, and biſhop Athanaſius, 880: and they are followed by thoſe of ſeveral others. The coinage of *Venice* begins in the 10th century, with ſilver pennies, marked VENECI. In 1280 the firſt Venetian gold appears; and the firſt copper in 1471. The ſilver groats are as old as 1192. *Florence* ſurpaſſes all the cities of Italy in the dignity of her coinage. Some ſilver pieces occur from the 12th century, or an earlier period; but in 1252, the famous gold coins, called Florins, from the flower of the lily upon them, appeared; and were imitated by the popes, France, and England, as being the firſt gold coins ſtruck in Europe, after the eighth century, for during five centuries no gold worthy of notice was ſtruck in Europe. The florins of Florence have on one ſide St. John the Baptiſt ſtanding, S. IOHANNES. B. on the other a large fleur-de-lis, FLORENTIA; and the coins of the popes, France, and England reſembling them, have the ſame types, but different legends. They weigh a drachm, and are no leſs than 24 carats fine, according to Italian writers; being intrinſically worth about 12*s.* The firſt coins of *Genoa* are of Conrad the emperor, 1129, DUX IANVÆ. Thoſe of the dukes of *Savoy* begin in the ſame century. The patriarchs of *Aquileia* iſſued coins from 1204 till 1440. *Ferrara* has coins of marquiſes from 1340. In France, the coins of the firſt race from Clovis 490, till its termination in 751, are chiefly gold trientes, well wrought, with the heads of the kings. Some ſolidi and ſemiſſes alſo appear. Theſe coins, which properly belong to the claſs of *antient* coins, have on the obverſe the king's head and name, but ſometimes the name of the Moneyer; the reverſe has a croſs with the name of the town. The coins of the ſecond race, beginning with Pepin in 750, and extending to Hugh Capet in 987, commence the *modern* claſs. Theſe are no leſs barbarous than the others are elegant: they are almoſt all ſilver pennies, and very ſeldom bear the head of the king. Thoſe of Charlemagne have only CAROLUS in the field, while the reverſe bears R. F. or ſome ſuch inſcription. One piece alone, ſtruck at Rome, has a rude buſt of him. The third race, beginning with Hugh in 987, and extending to the revolution, are unfortunate in their coins, till the time of St Louis, in 1226, when the groat appears, and the coinage began to improve. The groat, or groſſo, ſo called in compariſon with the penny, paſſed from Italy to France, Germany, and England. In the time of St. Louis, deniers of billon were iſſued, and were followed by other pieces of the ſame metal, as the liard or hardi of three deniers, the maille or obole of half a denier, the pougeoiſe or pite of one quarter. In the time of Henry III. 1574, copper was firſt uſed in French coinage. Other remarkable coins of France are the blancs, or billon groats, firſt iſſued in 1348; the ecus a la couronne, or crown of gold, the moſt famous French coin, ſo called from the crown on one ſide, and begun by Charles IV. in 1384; the teſton, or piece with the king's head, of Louis XII.; the elegant Henri of Henry II. which has Gaul ſitting in armour, with a victory in her hand, OPTIMO PRINCIPI; exergue GALLIA. The firſt Louis d'or is of 1640. *Spain* vies with France in the elegance of her early ſeries, which conſiſts almoſt wholly of trientes of gold finely executed. On one ſide they bear the head of the king, with his name, and on the other a croſs with the name of the town. While the Moors, or Arabs, poſſeſſed Spain, from the eighth to the 13th century, and Granada in particular till the end of the 15th, ſuch was the influence of the Mahometan faith, that the Moreſque coins of Spain only preſent us with inſipid inſcriptions on both ſides: they are chiefly in gold; and the inſcriptions are in the old Arabic character, uſed in Mahomet's time, called the Cuphic. From Charlemagne the coinage of *Germany* commences; and the ſeries of emperors is thought to be nearly complete. The coinage of *Denmark* begins with Canute the Great, in 1014. After Canute, we find coins of Harold and Hardicanute, then of Magnus Bonus in 1041, with Runic reverſes and of neat workmanſhip. But without enumerating thoſe of Sueno II., which rarely have the buſt, with an arched crown, and on the reverſe curious ornaments of a teſſellated form running acroſs the field, with the IIIII on either edge of the ornaments; and thoſe of Harold I. in 1074, with generally two heads; the rude coins of Nicolas or Niel, of Waldemar I. and of his ſucceſſors; thoſe of Olaf in 1376, bearing a grinning full face, with a crowned O on the other ſide; and the billon coins of Eric in 1426:—we paſs into *Sweden*, which is ſaid to have begun her coinage under Biorno in 818, on the plan of that of Charlemagne; theſe coins have a croſs, though Biorno was not a Chriſtian; the next coins are of Olaf, OLVF REX SVEVORVM, &c. &c. the ſeries proceeding till Margaret in 1387. From her time to that of Guſtavus Vaſa, in 1520, the coins are of Daniſh monarchs, ſtruck for Sweden. Of Guſtaf Waſe, or Guſtavus Vaſa, and his ſucceſſors, there are many fine coins. In 1634 ducats were coined with the buſt of Guſtaf Adolf, who died in 1632; reverſe the arms of Sweden, with the chymic types of mercury and ſulphur. In 1716, and the two following years, the ſmall copper coins with Saturn, Jupiter, Mars, &c. were iſſued by Charles XII. to paſs for dollars, on account of his want of money. The coins of *Norway* begin with Olaf, in 1066, and are followed by thoſe of Magnus, Harald, &c. &c. Of Denmark, Sweden, and Norway there are alſo eccleſiaſtic coins, as of Germany, France, &c. ſtruck by the chief biſhops. *Bohemia*, the moſt weſterly Slavonic kingdom, boaſts the earlieſt coinage; the firſt coins are thoſe of duke Boleſlaus I. in 909, with his head and name. The coinage of *Poland* is nearly as ancient as that of Bohemia; and it may be obſerved in general, that the coinage of the Slavonic kingdoms follows the model of the German. The coins of *Ruſſia* are of very late date. None of her coins ſeem to be more ancient than the 13th century. The firſt Ruſſian coins have rude figures of animals on one ſide; and a man, ſtanding, with a bow or ſpear, on the other. Some have St. George and the dragon, and various other types. Such are all kopeks, or ſilver pennies. The rouble or dollar, and its half, begun under Ivan or John in 1547. Thoſe of the falſe Demetrius, in 1605, are very ſcarce. In 1230, the knights of the Teutonic order, having conquered the Pagan inhabitants of *Pruſſia*, coined ſilver pennies on the German plan, at Culm. In the next century were ſtruck ſhillings, groats, and ſchots, the laſt being the largeſt and very rare; they have the Pruſſian ſhield, an eagle ſurmounting a croſs, within a roſe-ſhaped border, MONETA DOMINORUM PRUSSIE; reverſe a croſs fleurie, within a like border, HONOR MAGISTRI JUSTITIAM DILIGIT. In the ſame century gold coins were ſtruck. In 1525 the money was ſo debaſed, that 12 or 13 marks were worth but one mark of ſilver. The coins of Brandenburg and Poland are the later coins of Pruſſia.

We ſhall now proceed to give a brief enumeration of the coins of *Britain*. The Heptarchic coins are only of two ſorts; the ſilver ſkeatta or penny, and the copper or billon ſtyca; the latter being known only in Northumbria, and being a very ſmall piece, worth about half a farthing. The ſilver penny may be regarded as the general heptarchic coin. The ſkeattas were ſtruck in Kent, and the other ſtates of the Heptarchy

Heptarchy from the ſixth to the eighth century, or from about the year 500 till 700. No heptarchic pennies occur till after the year 700; but ſkeattas, which Dr. Combe, by cauſing two plates of them to be engraved, has brought into notice, are found with the name of Ethelbert I., king of Kent, A. D. 560—616, and of Egbert, alſo king of Kent, A. D. 664. The heptarchic pennies are, therefore, almoſt all of the eighth century, or from 700 till 832, when Egbert terminated the ſeven kingdoms. The coins of the chief monarchs preſent almoſt a complete ſeries, from Egbert 832 to Edgar 959. Of Ethelbald 857, and Edmund Ironſide, A. D. 1016, there are no coins. Moſt of them bear rude portraits, and the reverſes have views of cathedrals and other buildings, &c. The inſcriptions are alſo ſometimes curious. Eccleſiaſtic coins alſo appear of the archbiſhops of Canterbury, Wulfred, A. D. 804, Ceolnoth, 830, and Phlegmund, 889. The Norman conqueſt in 1066 made no alteration in the Engliſh penny, the only coin. The old Engliſh penny, or anglicus, Mr. Pinkerton obſerves, was a coin celebrated all over Europe in the middle ages, and almoſt the only money known in the northern kingdoms. In neatneſs of fabric, and in purity of metal, it is ſuperior even to the Italian and French coins of that period. The ſeries of Engliſh pennies extends almoſt without any failure from Egbert to the preſent reign. The kings wanting are John and Richard I. The Rev. Mr. Southgate, generally learned and peculiarly ſkilled in medals, has in his cabinet as neat and complete a ſeries of this knid as is perhaps to be found. Several uniques, or almoſt ſuch, are found there in the beſt preſervation; ſuch as the French penny of Richard I., the penny of Richard III, the full-faced penny of Henry VIII. in fine ſilver, and others. The firſt Engliſh pennies weigh $22\frac{1}{2}$ grains troy: toward the cloſe of Edward III. the penny weighs but 18 grains, and in the reign of Edward IV. it fell to 12. In Edward VI's. time, 1551, the penny was reduced to eight grains, and after the 43d of Elizabeth to $7\frac{23}{31}$ grains, at which weight it continues to this day. The next coins in antiquity, purſuing the ſilver coinage, are the halfpennies and farthings, firſt ſtruck by Edward I. about 1280, ſome having been previouſly iſſued in Ireland by John. The firſt were continued down to the commonwealth, ſince which time none have been ſtruck in ſilver: the farthings ceaſed with Edward VI. To theſe ſucceeds the groat, from Fr. gros, a large piece, introduced by Edward III. in 1354. The half-groat, or two-pence, is of the ſame date. Next to the groat is the teſtoon, or ſhilling, firſt coined by Henry VII., in 1503. The appellation of teſtoon was derived from the teſte, tête, or head of the king upon it. The ſhilling was at firſt a German appellation, ſchelling; coins of that name having been ſtruck at Hamburgh in 1407. The crown was publiſhed by Henry VIII. in ſilver, whereas it had before appeared only in gold; whence the old phraſe "crowns of gold;" and the half-crown, ſixpence, and three-pence, by Edward VI. Elizabeth, in 1558, coined three-halfpenny, and in 1561 three-farthing pieces, but they were dropped in 1582. From the 43d of Elizabeth, 1601, the denominations, weight, and fineneſs of Engliſh ſilver remain the ſame to the preſent time. It was about the year 1257 that Henry III. formed the deſign of a gold coinage, and ordered it to be current in the kingdom: however, no more than two ſpecimens of it have reached us. It is called a gold penny, but larger than a ſilver one. But it is from Edward III. that the ſeries of gold coinage commences, for no more occurs till 1344, when that prince firſt ſtruck florens, ſo called from the beſt gold then coined at Florence. The floren was then worth 6*s.*, but is now intrinſically worth 19, from the increaſed value of gold, and diminution of ſilver coins. The half and quarter of the floren were ſtruck at the ſame time, and of the ſame proportional value. In the ſame year the noble was announced, of 6*s.* 8*d.* value, and conſequently forming half a mark, being then the moſt general ideal mode of money. This was attended by its half and quarter; the proportion of ſilver to gold being then 1 to 11. This coin, together with its ſubdiviſions, continued the only gold coins till the angels of Edward IV. 1465, ſtamped with the angel Michael and the dragon, and the angelets, half the angel, or 3*s.* 4*d.* was ſubſtituted in their place. Henry VIII. in 1527, added to the gold denominations the crown and half-crown, at their preſent value; and, in the ſame year, gave ſovereigns of 22*s.* 6*d.* and ryals of 11*s.* 3*d.*, angels of 7*s.* 6*d.*, and nobles at their old value of 6*s.* 8*d.* In 1546, the ſame ſovereign, making the value of ſilver to gold as 1 to 5, ſtruck ſovereigns of the former value of 20*s.*, and half-ſovereigns in proportion. The gold crown of Henry VIII. is about the ſize of our ſhilling, and the half-crown of a ſixpence, but thin, as all hammered money was in modern times. His gold coin, like his ſilver, is much debaſed. Theſe coins continued, with a few variations, till Charles II. eſtabliſhed the preſent ſorts of gold coin. Till Edward VI. our monarchs appear upon their gold coin at full, or three quarters, length; that prince being the firſt whoſe buſt only is ſeen. Silver, which had been to gold for ſome time as 1 to 4, was again reduced in 1551 to its old proportion of 1 to 11. Upon the union of the crowns, James I. of England gave the ſovereign the name of unite, it being then of 20*s.* value. Of him are likewiſe roſe ryals of 30*s.* and ſpur ryals of 15*s.* angels of 10*s.* and angelets of 5*s.*; till his ninth year, when gold was raiſed in the proportion of 1*s.* in 10*s.* Silver, which had fallen in its proportion to gold from the degree of 1 to 12, now ſunk further, as 1 to $13\frac{1}{2}$ in weight. The gold crown and half-crown continued to this prince incluſive, and the crown to his ſucceſſor. The ſovereign, which had been commonly termed the broad-piece, under the commonwealth aſſumed the uninvidious name of the twenty-ſhilling piece, which it retained till it was ſupplanted by that of the guinea. The commonwealth likewiſe ſtruck ten-ſhilling and five-ſhilling pieces in gold. Oliver publiſhed none but forty-ſhilling and twenty-ſhilling pieces, and very few even of theſe; the former in particular being moſtly patterns. The guinea, ſo called from the Guinea-gold out of which it was firſt ſtruck, was proclaimed in 1663, and to paſs for 20*s.*; but it never went for leſs than 21*s.* by tacit and univerſal conſent. It is only twenty-two carats fine, and two alloy, which is the ſtandard of our gold coinage to this day. Charles II. likewiſe iſſued half-guineas, double-guineas, and five-guinea pieces, which have been all continued through every reign to the preſent time, though the latter two are not in common circulation. Geo. I. publiſhed quarter-guineas, an example imitated by his preſent majeſty; but theſe laſt of George III. were found ſo troubleſome and apt to be loſt, that they were ſtopped within a year or two when received at the bank of England, and thus ſilently annihilated. Pieces of 7*s.* were likewiſe coined, and have been continued: they are known by the lion above the helmet. The laſt coinage is that of copper. The firſt money coined in ancient Britain ſeems to have been copper. But the Saxons never thought of coining except in the inſtance of the ſtyca. While copper coin continued to be wanting in the Engliſh authoriſed money till the year 1672, with a few ſmall exceptions after the time of Elizabeth, we need not much wonder that in more remote periods its deficiency was not at all felt. The known averſion of that queen,

queen, and of the nation in general, to a copper coinage, was owing to the counterfeit money called "black money," being always of copper mixed or washed with about a fifth part of silver. The term of "black money" evidently arose from contradistinction to "white money," which is yet a name for that pure silver which it was made to imitate. When it is considered, therefore, that the base money was always of copper, it is no wonder that the idea of a copper coinage should be confounded with that of an imposition of authorised bad money. In 1594, when the practice of coining tokens, upon the returning which to the issuer, current coin, or value was obtained, had got to a great length, government had serious thoughts of a copper coinage; and a small copper coin was struck, of about the size of a silver two-pence, with the queen's monogram on one side, and a rose on the other, the running legend being THE PLEDGE OF—A HALF-PENNY. The queen, however, retaining her aversion to a copper coinage, the scheme proved abortive; nor was it revived till the succeeding reign, when, on the 19th of May 1613, king James's royal farthing tokens commenced by proclamation. They are mostly of the same size with the above, and have upon one side two sceptres in saltier, surmounted with a crown, and the harp upon the other. Their legend is the king's common titles running upon each side. These pieces, which were issued merely as pledges or tokens, for which government was obliged to give other coin if required, were not favourably received; but continued in a kind of reluctant circulation through this reign and the beginning of the next. In 1635 Charles I. struck those with the rose instead of the harp. But their currency was stopped by the number of counterfeits and the king's death in 1648; and then the tokens of towns and tradesmen again took their run, and increased prodigiously till 1672, when farthings, properly so called, were first published by government. After many trials for improving the copper coinage, and the issuing of many copper farthings, current half-pence and farthings first began in 1670 to be struck at the Tower; but they were not proclaimed till August 1672. These continued till the last year of Charles II., 1684, when disputes arising about the copper, tin farthings were coined with a stud of copper in the centre, and inscribed round the edge as the crown pieces, with NUMMORUM FAMULUS, 1685 or 1686. Half-pence of the same kind were issued in 1685, and tin continued to be coined till the year 1692. But in 1693 the tin was called in, and the copper coinage commenced anew. All the farthings of the following reign of Anne are trial pieces, except that of 1714, her last year. They are beautifully executed; but the one whose reverse is Peace in a car, PAX MISSA PER ORBEM, is the most esteemed. It is observable with regard to the copper coinage, that the intrinsic worth of the metal is not one-half of its currency. The pound of copper, worth 10*d.*, yields 46 half-pence, or 23 pence, when coined. Hence forgeries even of good metal yield a large profit, and the whole kingdom swarms with counterfeit copper, insomuch that not a fiftieth part of that currency is legitimate; an evil which requires remedy. Before we close this subject of the English coinage, we shall mention the Portcullis coins of Elizabeth, issued in rivalship of the Spanish king, for the service of the East India company, in their settlements abroad. They are of different sizes from the crown downward, and are easily distinguished by the portcullis on the reverse. To them succeeded the various siege pieces of Charles I. in gold and silver, some of the latter being so large as to be of 20*s.* value.

The coinage of Scotland did not commence till a late period. There is room to believe, says Mr. Pinkerton, that silver pennies exist of Alexander I., 1107, as some are found with that name, apparently of ruder and more ancient fabric than those of Alexander II., 1214. Of David, 1124, there are coins. Those of William, 1165, are numerous, with LE REI WILAM, or WILAM RI, or RE; the last word used in Scandinavia for king, or perhaps a various spelling of the old French *Rei*. A large hoard of William's pennies was found near Inverness in 1780. The Scottish money continued to be the same with that of England in size and value till the time of David II., 1355, whose vast ransom drained the Scottish coin, and occasioned the size of that which remained to be diminished. After this ransom, the Scottish coin gradually diminishing, in the first year of Robert III. it passed only for half its nominal value in England; and at length, in 1393, Richard II. ordered that it should pass only for the weight of the genuine metal in it. It sunk by degrees, till, in 1600, it was only a twelfth part value of English money of the same denomination, and so remained till the union of the kingdoms cancelled the Scottish coinage. In silver, we have only pennies of Alexander II., who reigned till 1249; but Alexander III., who reigned till 1293, coined half-pence. Of Robert I., 1306, and David II., there are silver farthings. The groat and half-groat, introduced by David II., completed the denominations of silver money till the reign of Mary, when they all ceased to be struck in silver. In 1544, the second year of Mary, Scottish money was a fourth of that of England. About the year 1553, shillings or testoons were first coined, bearing the bust of the queen, and the arms of France and Scotland on the reverse: they were then worth 4*s.* Marks of 13*s.* 4*d.* Scottish were also struck, worth 3*s.* 4*d.* English. In 1565 the coin was to the English as 1 to 6; the silver crown being then first struck, weighing an ounce, and passing for 30*s.* Scottish; and lesser pieces of 20*s.* and 10*s.* were struck in proportion; and these have the marks upon them xxx, xx, x, to express their value. In the time of James VI., 1571, the mark and half-mark Scottish were struck, the former being worth about 22 pence and the latter 11 pence English. In 1578 the famous NEMO ME IMPUNE LACESSET occurs first upon the coin; the invention of which is ascribed to Buchanan. The Scottish silver, coined after the union of the crowns, it is hardly necessary to mention.

The gold coinage of Scotland resembled the English; Edward III. having given the first currency in this metal in 1344. About 30 years afterwards, Robert II. issued his. The gold coins of Scotland, however, are of much smaller model than the English. They were first called St. Andrews, from the figure of that tutelar saint upon his cross, who appears upon them, with the arms of Scotland, a lion in a shield, on the reverse. The lion was another name for the largest gold coin, from the Scottish arms upon it; next was the unicorn under James III.; and the chief gold pieces of James V. were the bonnet pieces, so called from the bonnet in which that king's head appears upon them. The last gold coinage of Scotland is the pistole and half-pistole, coined by William III. in 1701, worth 12*l.* and 6*l.* Scottish. They have the sun under the head.

The copper coinage of Scotland, though more current than that of England, is not of so early a date as some would ascribe to it. Buchanan speaks confusedly of copper coinage in Scotland before James III.; but in this he is mistaken. During the reign of James III., says Pinkerton, the copper coinage began, and speedily increased in its pieces. The old Scottish coins of copper stood thus:

A Penny	=	$\frac{1}{12}$ of a penny English.
A Bodle	=	2 pennies.
A Hardie	=	3 pennies, the farthing English.

A Plack	=	4 pennies.
A Baw-bee	=	6 pennies.
An Atkinſon	=	8 pennies.

N. B. The penny has a little dot behind the lion; the bodle, alſo called two-penny piece and turner, has two dots. This coinage continued the ſame through the reigns of Charles I. and II. The Scottiſh pennies of Charles II. are not very uncommon; they weigh only 10 grains. In Scotland there are no eccleſiaſtical coins; though they occur in Denmark, Norway, and almoſt all other kingdoms.

With reſpect to the coins of Ireland it may be obſerved, that, from their form and fabric, the old made pennies found in this country were ſtruck by the Danes there. Of Anlaf, 930, and Sihtric, 994, there are coins ſtruck at Dublin, ON DVFLI, or DYFLI, Duflin or Dyflin being the real Daniſh original name of this fine city, as of towns in Scandinavia. Coins of Donald, an Iriſh monarch, probably Donald O'Neal, 956, are publiſhed by Simon. Other Daniſh and Iriſh kings have coins. The pennies ſtruck by Engliſh monarchs in Ireland are remarkable: ſuch, with the name of Dublin, occur of Ethelred, 866; Edred, 948; Edgar, 959; and one of Canute, 1017. The Iriſh coins from John to Henry V. are known by the triangle encloſing the king's head, and by the names of Iriſh towns on them: after Henry V. they are only diſtinguiſhed by the names of Iriſh cities where they were ſtruck. The harp is never ſeen upon Iriſh coin till the reign of Henry VIII. The difference between the Iriſh coin and the other money ſtruck by the kings of England begins in the time of Henry VIII., who coined ſix-pences for Ireland, only worth four-pence in England. Mary iſſued baſe ſhillings and groats for Ireland; and Elizabeth's baſe money for Ireland is notorious. In 1601, copper pennies and half-pence were coined for Ireland by Elizabeth, though ſhe would not conſent to a copper coinage in England. In 1635 a mint was eſtabliſhed in Dublin by Charles I.; but the maſſacre and diſturbances in that country put a ſtop to it, and the plan was never reſumed. After that maſſacre, 1641, the Papiſts ſtruck what are called St. Patrick's half-pence and farthings, known by the legends FLOREAT REX, reverſe ECCE GREX; and the farthing QUIESCAT PLEBS. In Cromwell's time, copper tokens were ſtruck by towns and tradeſmen, as in England. In 1680, half-pence and farthings were given by authority, with the harp and date. James II., arriving in Ireland from France in 1689, inſtituted a mint, and iſſued ſhillings and half-crowns, ſtruck of all the refuſe metal which could be procured: for this purpoſe ſome braſs guns were uſed, ſo that the coinage is generally called gun-money. Pennies and half-pennies of lead mixed with tin were publiſhed in 1690; and other crowns of gun-metal, of the ſize of half-crowns, without the mark of the month, in the ſame year. The crowns of white metal, which are very ſcarce, have James on horſeback, with titles no longer his; and on the reverſe the arms, CHRISTO VICTORE TRIVMPHO, with this legend on the rim, MELIORIS TESSERA FATI ANNO REGNI SEXTO. The patent of William Wood, eſq., acquired from George I, for coining half-pence and farthings, occaſioned great diſcontent, on account of the great loſs that attended it. Theſe coins are of very fine copper and workmanſhip, and have the beſt portrait of George I., perhaps, any where to be found. Sir Iſaac Newton, then at the head of the mint, ſaid they were ſuperior to the Engliſh in every thing but ſize. In 1737, 10th of George II., Iriſh half-pence and farthings were again coined of juſt ſize and weight, with the harp only on the reverſe; and the like are continued to this day. As they have no mint in Ireland, they are all coined here, and ſent to that kingdom. In 1760 the ſcarcity of copper coin in Ireland was relieved by a ſociety of Iriſh gentlemen, who obtained leave to coin half-pence; which appeared with a very bad portrait of George II., and VOCE POPULI round it. Since the abolition of the mint erected by Charles I., which happened about 1640, no gold or ſilver coins have been ſtruck with the Iriſh badge, but copper only. See COIN, COINAGE, and MONEY.

Modern Medals.—In the middle ages medals were quite unknown. Till the 15th century no medals appear of any country in Europe, if we except Scotland, which can boaſt of gold medals of David II. 1330—1370, ſtruck in England during his captivity. In the next century medals appeared in Italy, and from that time ſucceſſively in moſt countries of Europe. The gold medal of the council of Florence, 1439, is one of the earlieſt of theſe medals. Some indeed have mentioned, that of the famous reformer, John Huſs, in 1415, as the firſt. Vittore Piſano, a painter of Verona, is celebrated as perhaps the chief reſtorer of this branch of art. His medals, however, have no ſimilarity to thoſe of antiquity, being very large, and all caſt: they were firſt modelled in wax, then a mould was taken from the model in fine ſand and other ingredients. When a good caſt was procured, it was touched up, and made a model for the reſt. Vaſari, in his lives of the painters, gives us a catalogue of the medals done by Piſano. The papal medals are not only the moſt elegant, but the moſt ancient ſeries in modern Europe. Paul II., created pope in 1464, is the firſt pontiff who has medals of his own time. After Paul II., coeval medals are found of all the popes. In the time of Alexander VI., 1492—1503, the elegance of the papal medals begins to dawn; but his ſucceſſors Julius II, Leo X, Hadrian VI., and Clement VII., were ſingularly fortunate in having many of their medals deſigned by Raffaele, Julio Romano, and other great painters; and executed with correſponding workmanſhip. The medal of Julius II., with Saul, CONTRA STIMULUM NE CALCITRES, is the firſt medal, according to Venuti, that was ſtruck, not caſt. The medal of Julius III., reverſe a Ganymede ΦΕΡΝΗ ΖΗΝΟΣ ΕΥΦΡΑΙΝΕΙ, the dower of Jove delights, the deſign of which is aſcribed to Michael Angelo, is denied to be genuine by the pontifical writers. But there is a fine medal, deſigned by Parmegiano, of Gregory XIII., upon the correction of the calendar; reverſe a ſerpent, with his tail in his mouth, and a ram's head for the ſign Aries, in the centre, ANNO RESTITUTO, M.D. LXXXII. marked I. PARM. beneath the pope's buſt, in the obverſe. Beſides the papal medals, there are many of the various ſtates in Italy. Next to Italy, France is the moſt remarkable country for medals. But the French medals are neither fine nor numerous, till the reign of Louis XIV., who has exceeded all modern princes in this way. In Denmark, there are medals of Chriſtian II. 1516, and of Frederic and Sophia, 1532. Of Frederic II. and Chriſtian IV. there are many medals. The elephant of the houſe of Oldenburg is very frequent on Daniſh medals. In Sweden there are many fine medals of Guſtaf Waſe, or Guſtavus Vaſa. Chriſtina appears on ſeveral, ſtruck chiefly at Rome after her abdication. Of Charles XII., there are ſeveral curious medals. The medallic hiſtory of Holland begins in the year 1566. In the Spectator a Dutch medal is quoted as Engliſh; namely, that on the defeat of the Spaniſh armada, a fleet, FLAVIT ET DISSIPATI SUNT, 1588. Many Dutch medals are remarkable for maps and plans. The Spaniſh medals begin, as Mr. Pinkerton ſuggeſts, with Conſalvo, the great captain, in 1503; and many of them are curious and intereſting. Germany and Spain were as one empire under Charles V., of whom there are many medals. But

But the German ones begin with Frederic III., of whom there is one struck at Rome 1453; next is Maximilian 1504, who appears in the bonnet, worn before hats were invented about 1560, and a wheel on the reverse, PER TOT DISCRIMINA. There is a curious medal upon the death of Louis, king of Hungary, at Mohatz, 1526, when he fell fighting against the Turks; obverse his head, and that of his queen, face to face; reverse a battle. The medals of John of Leyden, leader of the Anabaptists, 1534, 1535, are singular monuments of folly and fanaticism. They bear his bust, with German inscriptions and legends. Amongst other curious medals, there is one of Sebastian, king of Portugal, famous for his unfortunate expedition in Africa, 1578, with his bust, full face, and three quarters length, SEBASTIANUS D. G. REX PORTUGALLIÆ, ARABIÆ, INDIÆ, ET AFRICÆ ANNO ÆTATIS XVI., reverse a shell-fish in the sea, the moon and seven stars, SERENA CELSA FAVENT. There is another singular medal of Catherine of Medici, queen of France, notoriously addicted to astrology. It represents her naked, between Aries and Taurus, with the name EBULLA ASMODÆA, over her head; she holds a dart in one hand, and a heart in the other; in the exergue is OXIEL.

As soon as medals began to revive, they became satiric; a quality almost unknown to the ancient mint. Medals among the moderns have been the chief article of satire, till the printshops took up the trade. The first satiric medal, it is believed, was struck by Frederic, king of Sicily, in 1501, against his enemy, Ferdinand, king of Spain. It bears the head of Ferdinand, FERDINANDUS R. AR. VETUS VULPES ORBIS; reverse a wolf carrying off a sheep, JUGUM MEUM SUAVE EST ET ONUS MEUM LEVE. It is said that in 1588, Elizabeth, queen of England, struck a medal, with the Spanish and English fleets, HESPERIDUM REGEM DEVICIT VIRGO. Philip, king of Spain, caused medals of the same impression to be distributed in England; but with this addition, NEGATUR, EST MERETRIX VULGI. The queen suppressed them, and published another medal, with this legend,

> "Hesperidum regem devicit virgo Negatur,
> Est meretrix vulgi, Res eo deterior."

Above all nations, the Dutch have most distinguished themselves for satiric medals; and have paid dearly for this kind of presumption. A great number of medals have been struck for private men of eminent learning or talents, and in this respect modern medals are superior to the ancient.

Mr. Pinkerton closes his account of modern medals with a comparison between these and the ancient medals. The most surprising difference between the ancient and modern works of art lies in the portraits. The ancient artists, even of the lowest class, marked the character, and exhibited the life and spirit of the person whom they represent; while the moderns only produce a kind of model, with very faint features of the character. The ornaments of the portraits have also this effect; the ancient being simple and picturesque in real life; whereas ours are discordant and ungraceful. The reverses of ancient medals, when consisting of human figures, or detached objects, exceed the modern in every view of strength, elegance, or taste. But in landscape, and all that belongs to perspective, the modern excel the ancient to a prodigious degree. A great fault of modern reverses, as of modern portraits, is that the manners of the time and country are very often totally perverted in them. Personifications are of all ages and countries and languages; but what title have heathen gods or goddesses to exist on our medals, and attract the adoration of our connoisseurs? Mr. Pinkerton, taking advantage of Dr. Coningham's tract on modern medals, makes some remarks on the legends. But for the different kinds of legends that are confined, we refer to the article LEGENDS, in which the reader is desired to correct the error of the press in the name of Coningham.

The first English medal is in the duke of Devonshire's cabinet. It is in brass, of a large size, upon the plan of the early Italian medals, being done without doubt in Italy; and bears on one side a bust IO. KENDAL RHODI TVRCVPELLE-RIVS, reverse the arms of Kendal, TEMPORE OBSIDIONIS TVRCORUM. MCCCCLXXX. The next English medal is that of Henry VIII. struck in 1545; it is of gold, larger than a crown-piece, and has the king's head full-faced on the obverse, with three legends within each other, of his titles and other matter. The reverse contains two inscriptions, declarative of his being head of the church, &c. the first in Hebrew, the other in Greek. This was imitated in all points by his successor Edward VI. in his coronation medal, being the first we have. Elizabeth presents us with a good number of medals, one or two of which are tolerable, but the rest very poor, inferior to those of Philip and Mary, two of whom in silver by Trezzo are of high relief, and good execution. Decent medals appear of James I. and his queen; and a very large one of Charles I. and Henrietta, in 1636, deserves notice for its fine workmanship. The reverse represents Justice and Peace, kissing, aukwardly enough; but the execution of the king's bust, and that of his lovely queen, is very masterly. The medals of Charles I., who was a lover of the arts, are various and curious; but we cannot enlarge in the enumeration of them. The commonwealth and Oliver Cromwell, were singularly fortunate in having the celebrated Simon for their artist in this line. The medals and coins of Simon are deservedly regarded as the most admirable which modern times have produced. Of Charles II. there are several good medals, as on his leaving Holland, his restoration, and coronation. The short reign of James II. has several medals, the most remarkable of which are the NEMO ME IMPUNE LACESSET; that with his queen, FORTES RADII SED BENIGNI; those on the Pretender's birth, FELICITAS PUBLICA. William III. gave occasion for many interesting medals. Those after his accession to the English crown, have generally his head and Mary's joined, as the MAJUS PAR NOBILE; ATAVUM PRO LIBERTATE; NEC LEX EST JVSTIOR VLLA; NISI TU QUIS TEMPERET IGNES; and others. Many medals also occur of James II., after his abdication, and of the other pretenders, done in foreign countries by eminent artists. Queen Anne has several fine gold, silver, and copper medals; of the first only two or three different pieces were struck; but in the other medals of this princess, we have a series of all the great events with which Marlborough illuminated her reign. About 1740, and for some years before and after, Dassier, a native of Geneva, settling in London, engraved a series of medals of all the English kings, with great taste and spirit. They are struck upon fine copper, and amount to thirty-six in number. He likewise gave medals of many illustrious men of this and other nations, which, says Pinkerton, deserve considerable praise. The various medals of eminent private persons in England are very numerous. Those who wish for fuller information of English medals than our limits allow, and the preceding extracts furnish, may consult Pinkerton's Essay so often cited, and Mr. Snelling's plates of them.

Of medals, of Scotland, which are numerous, we can only mention some of the principal. The fine gold pieces of David II. 1330—1370, which we have already noticed, are certainly medals. Another Scottish medal occurs of James III. 1478; it is of gold, weighing near two ounces, and its diameter is $2\frac{1}{5}$ inches. The obverse bears a beardless efs king, with long hair, fitting on a throne, holding in one hand a naked fword, in the other a fhield with the Scottifh arms. On the borders of the canopy, above the throne, is a Gothic infcription, IN MI DEFFEN, in my defence: the legend of the obverfe in Gothic letters is, MONETA NOVA IACOBI TERTII DEI GRATIA REGIS SCOTIÆ. The reverfe bears St. Andrew and his crofs, SALVVM FAC POPVLVM TVVM DOMINE. Another remarkable Scottifh medal is that inaugurative of Francis II. of France and Mary of Scotland, ftruck upon their coronation as fovereigns of France, and prefenting bufts of them face to face, with three legends, the outermoft of which contains their titles, and the middle one this fingular fentence, HORA NONA DOMINUS IHS EXPIRAVIT HELLI CLAMANS: the innermoft legend is the name of the city of Paris. The fine crown of Mary and Henry, 1565, is fo rare as to be efteemed a medal of the higheft value; it is fuppofed to be worth 40 or 50 guineas. Henry and Mary appear on it face to face, with their titles, and the reverfe bears the arms of Scotland, with this legend, QVOS DEVS CONIVNXIT HOMO NON SEPARET. Another remarkable medal of Mary gives her portrait full-faced, and weeping, O GOD GRANT PATIENCE IN THAT I SVFFER VRANG. The reverfe has this infcription in the centre, QVHO CAN COMPARE WITH ME IN GREIF—I DIE AND DAR NOCHT SEIK RELEIF; and this legend around, HOVRT NOT THE (figure of a heart) QVHAIS IOY THOV ART. The laft Scottifh medal, which we fhall mention, is the celebrated coronation medal of Charles I., when he underwent his inauguration at Edinburgh, 18th June, 1633. It was executed by Briot, an eminent French artift; and was the firft piece ftruck in Britain with a legend on the edge, being, it is fuppofed, the only one ever coined of gold found in Scotland. On the front is the king's buft, crowned and robed, with his titles. The reverfe bears a thiftle growing, HINC NOSTRÆ CREVERE ROSÆ. Around the edge is EX AVRO VT IN SCOTIA REPERITVR BRIOT FECIT EDINBVRGI, 1633. Few of thefe were ftruck on the Scottifh gold, three only being known to exift, of which one is in the mufeum. The piece is not uncommon in filver, in which metal it wants the legend on the edge, which conftitutes its chief curiofity and merit. It was in rivalfhip to this that Simon gave his fine medal of Oliver, the reverfe of which is an olive tree, NON DEFICIENT OLIVÆ.

MEDALS, *Hiftory of,* and *Account of Writers on this Subject.* The ftudy of medals affords fuch a variety of amufement and of inftruction, that we may naturally fuppofe it to be almoft as ancient as medals themfelves; and yet ancient writers do not furnifh us with a fingle hint of collections of this kind. In the days of Greece, a collection of fuch coins as then exifted would not be regarded as an acquifition of any great value, becaufe it muft have confifted only of thofe that were ftruck by the innumerable little ftates, which then ufed the Greek characters and language, and of courfe it would be regarded as a fort of domeftic coinage, precluded from extenfion by the narrow limits of the intercourfe that fubfifted between different provinces and countries. As foon as any communication was opened between the Romans and the Greeks, the Grecian coins were imitated by the Roman workmen, and preferved in the cabinets of their fenators among the choiceft treafures. In a more advanced period of the Roman empire, individuals muft have formed feriefes of Roman coins: for we find, in fact, that a complete feries of filver was lately found in our ifland, containing, inclufively, all the emperors down to Caraufius. From the decline of the Roman empire, moft branches of fcience were enveloped in great darknefs, till the revival of literature towards the end of the 15th century. When literature began to be cultivated in Italy, the ftudy of medals, connected with that of ancient erudition, began to engage attention. Accordingly Petrarch, who in modern times was amongft the firft perfons in Europe that afpired to the celebrity of learning and of genius, was likewife the firft to conftitute an example of the fcience of medals. This eminent writer, being defired by the emperor Charles V. to compofe a book that fhould contain the coins of illuftrious men, and to place him in the lift, with a noble pride anfwered, that he would comply with his defire, whenever the emperor's future life and actions deferved it. Availing himfelf of this circumftance, he fent that monarch a collection of gold and filver coins of celebrated men. "Behold," fays he to the emperor, "to what men you have fucceeded! Behold whom you fhould imitate and admire! To whofe very form and image you fhould compofe your talents! The invaluable prefent I fhould have given to nobody but you; it was due to you alone. I can only know or defcribe the deeds of thefe great men. Your fupreme office enables you to imitate them."

In the next age Alphonfo, king of Arragon, caufed all the ancient coins, that could be difcovered throughout all the provinces of Italy, to be collected, which he placed in an ivory cabinet and always carried with him; that he might be excited to great actions by the prefence, as it were, of fo many illuftrious men in their images. Anthony, cardinal of St. Mark, nephew of Eugene IV., who afcended the pontifical chair in 1431, had a vaft collection. Soon afterwards Cofmo de Medici began the grand mufeum of the family of the Medici at Florence; the moft ancient, as well as the moft noble, in the univerfe. Among a profufion of other monuments of ancient art, coins and medals were not neglected. About the fame period Matthias Corvinus, king of Hungary, formed a noble collection of coins, along with ancient MSS. and other valuable reliques of antiquity. The firft perfon who feems to have examined medals, and adduced them as vouchers of ancient orthography and cuftoms, was Agnolo Poliziano, or Angelus Politianus. Maximilian I., emperor of Germany, formed a cabinet of medals, by means of which Joannes Huttichius was enabled to publifh a book of the lives of the emperors, enriched with their portraits, delineated from ancient coins. M. Grollier, treafurer of the armies of France in Italy during part of the 16th century, had a great collection of coins in all metals. When, after the death of Grollier, thefe were about to be fent into Italy, the king of France bought them at a high price for his own cabinet of antiquities. Befides medals of brafs, this collection contained an affortment of gold and filver. Guillaume du Choul, a contemporary of Grollier, had alfo a good collection of medals, many of which were publifhed in his treatife on the religion of the ancient Romans, printed at Lyons in 1557. From the letters of Erafmus we learn that the ftudy of medals was begun, in the Low Countries, about the beginning of the 16th century. About the middle of that century, Goltzius, a printer and engraver, travelled over a great part of Europe in fearch of coins and medals, for works relating to them, which he propofed to publifh. At this time, as he informs us, there were in the Low Countries 200 cabinets of medals, 175 in Germany, more than 380 in Italy, and about 200 in France: to which we may add about 500 for our own country, which Goltzius did not vifit. The greater number, however, of thefe cabinets were of that clafs called cafkets of medals, including from 100 to 1000, or 2000 in number. If we except Italy, there are few countries, in which more ancient coins are found

found, than in Britain. Mr. Pinkerton suspects, that Camden was one of the first, if not the very first, of our writers, who produced medals in his works, and who must have had a small collection. In the 17th century, Speed's Chronicle, published in 1610, was illustrated with coins from sir Robert Cotton's cabinet. Henry, prince of Wales, bought the collection of Gorlæus, amounting, as Joseph Scaliger says, to 30,000 coins and medals, and left it to his brother, Charles I. Archbishop Laud bought 5500 coins for 600*l.* and gave them to the Bodleian library. Thomas, earl of Arundel and Surry, earl marshal of England, had, in his exuberant collection of antiquities, a rich cabinet of medals, gathered by Daniel Nilsum. The dukes of Buckingham and Hamilton, sir William Paston, sir Thomas Fanshaw, sir Thomas Hanmer, Ralph Sheldon, esq. Mr. Selden, and many more, are enumerated by Mr Evelyn, as having collections. To this number we may add the earl of Clarendon, the historian, and Charles I. The fine cabinet of this unhappy monarch was dissipated and lost in the civil commotions. Oliver Cromwell had also a small collection; and that of Charles II. is mentioned by Vaillant. We may add, that his present majesty possesses a tolerable collection of ancient gold coins. Since the time of Mr. Evelyn, many noble cabinets have been formed in this country, which we cannot recount. At present, the chief cabinets in Britain are those of the duke of Devonshire, the earl of Pembroke, earl Fitzwilliam, formerly the marquis of Rockingham's, the Hon. Horace Walpole, the Rev. Mr. Crachrode, the Rev. Mr. Southgate, Mr. Townley, Mr. R. P. Knight, Mr. Edward Knight, Mr. Tyson, Mr. Barker, Mr. Brown, Mr. Bootle, Mr. Hodsul, Mr. Austen; with Mr. Ord's Egyptian, Mr. Douce's small brass, and Mr. Jackson's British.

The museum, lately enriched by some of those abovementioned, and the universities, have also collections; and also the Lawyer's library, and one or two colleges in Scotland; to which might be added private collections both there and in Ireland. But that of the late Dr. Hunter deserves notice, as the greatest in Europe, if we only except that of the late French king. From the middle of the 17th century down to these times, almost every year has produced some new work, or new discovery, in the science of medals.

Of writers in this department of science, Mr. Pinkerton has enabled us to mention the following: in Italy, Enea Vico published, in 1548 or 1555, his "Discourses on the Medals of the Ancients." His example was imitated in France by Antoine le Pois, who in 1579 gave his "Discourse on the Coins and Seals of the Ancients." In 1665, Charles Patin published his "History of Medals, or Introduction to that Science." The last edition appeared in 1695. In 1692, Pere Jobert, or Joubert, presented to the public his "Science des Medailles," the best edition of which is that of 1739, by M. le Baron Bimard de la Bastie. In the year in which Jobert published his book, a work somewhat similar to it was published in the English language, entitled "The Greek and Roman History illustrated by Coins and Medals, representing their Religion, Rites, &c. by O. W. (Obadiah Walker,) London 1692, 12mo." In 1695, a translation of Jobert's work appeared under the title of "The Knowledge of Medals," ascribed to Walker. The "Numismata, or Discourse on Medals, ancient and modern," by Mr. Evelyn, was printed in 1697, fol. In 1720, Nicolas Haym, an Italian musician, published at London his "Tesoro Britannico," or British Treasury, in Italian and English. They who wish to proceed in this science, says Mr. Pinkerton, may peruse the most excellent and useful work of Froelich, entitled "Notitia Numismatum antiquorum illorum, quæ Urbium Liberarum, Regum et Principum, ac Personarum illustrium, appellantur," Viennæ, Pragæ, et Tergesti 1758, 4to.; and afterward such books of medals as they please, in chronological order as published, from Goltzius down to Pellerin and Combe. The following list of the best authors is given by Mr. Pinkerton For the general science he recommends Vico's work, and Patin's already mentioned. The study of the Greek coins may be begun with Goltzius "Historia Siciliæ et Magnæ Græciæ ex antiquis Numismatibus," Antwerpiæ 1644, fol. Recourse may then be h d to Gessner's "Thesaurus Numismatum," Tiguri 1738, two vols. fol. The productions of Pellerin, Paris 1762, and following years till 1778, making, with all the supplements, 10 vols. 4to., ought next to be perused Dr. Combe's publication of Dr. Hunter's coins of Greek cities, London, 1782, 4to., as it is the last, so it is the very best of the kind ever yet given. Of the Greek monarchic coins Gessner's is the most ample assemblage. The Roman consular coins will also be found in full detail in Gessner; and descriptions may be found in Vaillant's "Nummi Antiqui Familiarum Romanarum," Amst. 1703, two vols. fol, or the "Thesaurus Morellianus," Amst. 1734, two vols. fol., a later and a better work. The imperial coins of Rome are likewise amply displayed by Gessner; with whom, for the rare coins, should be read Vaillant's "Numismata Imperatorum Romanorum," published by Baldini at Rome, 1743, three vols. 4to., and Khell's "Numismata Imperatorum Romanorum," Vindobonæ 1767, 4to., a supplement to the Roman edition of Vaillant; Banduri's "Numismata Imp. Rom. a Trajano Decio usque ad Palaeologos," (or to the termination of the Byzantine empire) Lutetiæ, 1718, two vols. fol.; Occo's "Numismata Imp. Rom." The best edition is the second of Occo himself.

Of books on modern coins and medals, the first which ought to be perused by a British subject are those relating to his own country. He should begin with Mr. Clarke's "Connection of the Roman, Saxon, and English Coins," London 1767, 4to.; Mr. Lowndes's excellent "Report, containing an Essay for the Amendment of Silver Coins," Lond. 1695, 8vo.; Snelling's "Views of English Money," Lond. 1763, and following years, 4to.; and Folkes's "Tables of English Coin," Lond. 1763, 4to. Ducarel's "Letters on Anglo-Gallic Coins" are very considerable. English medals are published by Snelling and in Vertue's Account of Simon's works. On the Scottish coins the only books are those of Anderson and Snelling. The Irish are well displayed by Simon, in his "Historical Essay on Irish Coin," Dublin, 1749, 4to., with the supplement by another author 1767, 4to. For the account of the sources of information with regard to other modern countries, we must refer to Mr. Pinkerton's preface. The second edition of Mr. Pinkerton's "Essay on Medals" will supersede the necessity of constant reference to other works, not easily procured; and the reader will find, that the author has cited original authors, and availed himself of an examination of many of the coins themselves, which he has described. This elaborate work, in two small volumes, Lond. 1789, will afford to the student in this branch of science ample satisfaction. This edition, besides many corrections and additions, that very much contribute to the increased value of the work, is illustrated with prints of coins, engraven exactly of the form and size of the originals, forming specimens of all the principal sorts. In the advertisement to this new edition, the author expresses himself in terms of high commendation concerning Monaldini's "Istituzione antiquarion Numismatica," printed at Rome, 1772, 8vo., which, he says, is much superior to Jobert's "La Science des Medailles."

MEDALS, *Utility of the Study of.* Medals are of great importance to the ftudy of hiftory. They, indeed, furnifh the principal proof of hiftoric truth, as their evidence reaches to the moft remote ages and the moft remote countries. Vaillant fet the firft example, in his learned hiftory of the Syrian kings, printed at Paris in 1681, of fixing the dates, and arranging the order of events in ancient hiftorians, by means of thefe infallible vouchers. Thus he was enabled to afcertain, in a very great degree, the chronology and progrefs of events of three of the moft important kingdoms of the ancient world, *viz.* thofe of Egypt, of Syria, and of Parthia. Father Hardouin, Noris, and Bayer, have purfued the fame plan; and to them we may add Froelich, Corfini, and Cary. The ftudy of the Roman medals has a fuperior advantage to that of the Greek coins, as they ferve not only to illuftrate the chronology of reigns, but to aid us in the interpretation of particular events. To this purpofe, befides the portrait of the prince, and date of his confulfhip, or of his tribunitian power, we have a reprefentation, or poetical fymbol, of fome grand event on the reverfe. In a word, the feries of Roman coins prefents the very beft fuite of documents of the Roman hiftory, which the art of man could have invented. Befides its fervice to hiftory, the fcience of medals is without doubt of confiderable ufe to geography, to natural hiftory, to the illuftration of ancient writers, to architecture, and to the knowledge of a connoiffeur, or that of ancient monuments, bufts, ftatues, ceremonies, and the like; in all which views its utility is well illuftrated by examples in Pinkerton's valuable work. He has alfo evinced the connection of the ftudy of medals with the fine arts of poetry, painting, fculpture, and architecture. In the firft refpects, he has greatly improved upon Mr. Addifon's "Dialogues on the Ufefulnefs of ancient Medals." On this very interefting fubject, which Mr. Pinkerton has rendered no lefs amufing than inftructive, we cannot forbear making a few extracts. The Roman coins to a man of poetical imagination are very entertaining by means of the fine perfonifications and fymbols, which are to be found on their reverfe. *Happinefs* has fometimes the caduceus or wand of Mercury, which Cicero tells us was thought to procure the gratification of every wifh. In a gold coin of Severus, fhe has heads of poppy, to exprefs that our prime blifs lies in oblivion of misfortune. *Hope* reprefented as a fprightly damfel, walking quickly and looking ftraight forward. With her left hand fhe holds up her garments, that they may not hinder the rapidity of her pace; while, in her right hand, fhe holds forth the bud of a flower, an emblem infinitely more fine than the trite one of an anchor, which is the fymbol of Patience, not of Hope. *Abundance* is imaged as a fedate matron, with a cornucopia in her hands, of which fhe fcatters the fruits over the ground; but does not hold up her cornucopia, and keep its contents to herfelf, as many poets and painters make her do. *Security* ftands leaning on a pillar, indicative of her being free from all defigns and purfuits; and the pofture itfelf correfponds to her name. The emblems of *Piety*, *Modefty*, and the like, are equally appofite and poetical. The happinefs of the ftate is pictured by a fhip, failing before a profperous breeze; an image of which Gray has admirably availed himfelf in his "Bard." The different countries of the then known world are alfo delineated with great poetical imagery. To a Briton, it affords peculiar fatisfaction to fee his native ifland often reprefented upon the earlieft imperial coins, fitting on a globe, with a fymbol of military power, the "labarum," in her hand, and the ocean rolling under her feet. Coins alfo prefent us with countries and rivers, admirably perfonified. On the reverfe of a colonial coin, rude in execution, of Auguftus and Agrippa, infcribed IMP. and DIVI. F., the conqueft of Egypt is reprefented by the appofite metaphor of the crocodile, an animal almoft peculiar to that country, and at that period efteemed altogether fo, which is chained to a palm-tree, at once a native of the country and fymbolic of victory. Moreover, a cabinet of medals, of which Rubens is faid to have had a very fine collection, may be confidered as forming the claffic erudition of a painter. We may add, that almoft all the ufes which connect the fcience of medals with painting, render it alfo fubfervient to the art of the fculptor, who cannot lefs than profit by the ftudy of the Greek coins in particular. The connection of the ftudy of ancient coins with architecture, confifts in the views of many of the ancient edifices, which are found in perfect prefervation on medals. Froelich obferves, that the coins of Tarfus are very remarkable for a kind of perfpective in the figures. On others are found triumphal arches, temples, fountains, aqueducts, amphitheatres, circufes, hippodromes, palaces, bafilicas, columns and obelifks, baths, fea-ports, pharofes, and the like.

MEDALS *and Coins, Rarity of.* The fcarcity of coins, bearing any particular impreffion, muft be principally owing to the few that were ftruck with that impreffion, or their being called in, and iffued from the mint in another form. The firft is the cafe with the copper of Otho, and gold of Pefcennius Niger; the latter with the coinage of Caligula. Sometimes coins, formerly efteemed almoft fingular, will, in later times, become much more common in confequence of the high price at which they are rated, fo that they are brought to market as hoards of them are found. The firft was the cafe with the farthings of queen Anne; fome of which, formerly fold at five guineas, would not now fetch five fhillings; the latter with refpect to the coins of Canute, king of England, which were very rare till a large hoard of them was difcovered in the Orkneys. The coins of Greek cities are efteemed to be more common in copper than in filver; double the number exifting in the firft metal: thofe of Greek princes the reverfe, with a few exceptions, thofe of filver being more numerous. Of the Greek monarchic coins, the tetradrachms of the Syrian kings, the Ptolemies, the princes of Bithynia and Macedon, excepting Alexander the Great and Lyfimachus, are all rare. Thofe of Cappadocian kings are not found, except of fmall fize, and are fcarce. Of the kings of Numidia and Mauritania, Juba, the father, is common, the fon and nephew Ptolemy are fcarce. The kings of Sicily, in large filver, are rare: as are alfo thofe of Parthia. The kings of Judæa are rare; thofe of Arabia and Commagene only occur in brafs, and are fcarce; and likewife the kings of Bofphorus, who appear in electrum, and a few in brafs. The kings of Pontus, and Phileterus, king of Pergamus, are all rare. All didrachms, both of kings and cities, are fcarce, except Corinth and her colonies. The gold coins of Macedon, Alexander the Great, or Lyfimachus, are common: the others very rare. All filver tetradrachms of kings are accounted medallions, and bear a high price. One of the fcarceft of the fmall filver coins of the Greek princes is the didrachm of Alexander the Great. The Grecian monarchic money of copper may, in moft inftances, be confidered as rare.

Of the Roman coins, the confular ones reftored by Trajan are the rareft of their clafs. The gold confular coins are the moft rare, and the filver the moft common; excepting the coin of Brutus, with a cap of liberty between two daggers, EID. MART. which is fcarce, and a few other inftances.

Among the Roman imperial coins, we fhall only mention that

that of Otho in brafs; the fcarcity of which is owing to the fhortnefs and tumult of his reign. The fcarcity of other imperial coins is largely ftated by Mr. Pinkerton in his tables. The Roman coins in lead are all extremely rare. The heptarchic coins of Britain are moftly rare: the money of Alfred, bearing his buft, is rather fcarce; his other coin is very rare. The coins of Hardicanute are very fcarce. Of kings after the conqueft no Englifh coins of John are found, except Irifh only, and of Richard I. only French. In the Scottifh feries Alexander II. is rather fcarce. Coins of John Baliol are rare, and none of Edward Baliol are found. The gold money of Scotland has always been fcarce. See farther on this fubject the Appendix to Pinkerton's Effay on Medals.

In the fale of medals, thofe that are rare are fold feparate, but the common ones are put into large lots, fo that they are feldom bought but by dealers. The gold coins of Greek cities are generally very fmall; and not above a dozen ftates have thofe in gold: of thefe only Carthage, Cyrene, and Syracufe are rather common, and worth but double their intrinfic value. The other gold civic coins are worth from 5*l.* to 30*l.* The only two gold coins of Athens known to exift are in Dr. Hunter's collection, and if they were fold, they might bring the very higheft price a coin can bear. The filver coins of Greek cities are many of them extremely fcarce; the common ones are priced according to their fize, for the largeft are always the rareft. Thofe of Syracufe, Dyrrachium, Maffilia, Athens, and a few other ftates, are common; drachmas, and leffer fizes, might bring 5*s.* each; didrachms and tridrachms from 5*s.* to 10*s.* according to their beauty and prefervation. The tetradrachms, which are always moft valued, may, when belonging to cities whofe coins are common, bring from 7*s.* 6*d.* to 1*l.* 1*s.* Civic coins of filver that are rare are not eafily valued. Ten guineas have been given for one, and competition might triple that value. The common Grecian civic coins in fmall brafs bring from 3*d.* to 1*s.* 6*d.*, according to their prefervation. Others belonging to cities, which have not above two or more coins that are known, and thofe of brafs, bring much higher prices. With refpect to the gold coins of the Greek princes, thofe of no rarity in the coinage of Philip of Macedon, and Alexander the Great, bear but from 5*s.* to 20*s.* above the intrinfic value. But thofe of the other princes are rare, and bring from 3*l.* to 30*l.* a-piece, or more. Of the filver monarchic money, with Grecian legends, the tetradrachms, which are deareft, fell from 5*s.* to 50*s.*, and thofe that are very rare from 3*l.* to 30*l.* The drachmas may bring half thefe prices, and that of other denominations in proportion. The copper coins of the Greek kings are, generally, fcarcer than the filver, and ought to bring a high price. Ancient Roman Afes, with their divifions, bring from 2*s.* to 2*l.*, according to the fingularity of their devices. Confular gold coins are worth from 1*l.* to 5*l.*: the Pompey, with his fons, 21*l.*, and the two Bruti, 25*l.* The filver rate univerfally from 1*s.* to 2*s.* 6*d.*, except that with the cap of liberty and daggers, and a few others, which, if genuine, may bear from 10*s.* to 5*l.* The confular copper, though rarer than the filver, may be put at an equal price. The confular filver coins, reftored by Trajan, bear 1*l.* a-piece. Among the Roman imperial coins, with uncommon reverfes, we may reckon a filver piece of Auguftus, which will fetch from 4*s.* 6*d.* to 1*l.* 11*s.* 6*d.*; that with the legend C. MARIVS TROGVS bears 3*l.* 3*s.* Common gold coins of Trajan are not worth above 1*l.* The medals, with unknown characters, are fcarce and dear. Saxon pennies of the heptarchic princes are generally rare, and worth from 10*s.*, to 10*l.* each, according to fcarcity and prefervation. Thofe of the kings of all England, which are rare, are worth from 10*s.* to 2*l.* 2*s.*; excepting one or two very fcarce ones, fuch as Hardicanute, which would fetch 10*l.* 10*s.* Of Englifh medals, the gold ones of Henry, 1545, and of Edward's coronation, are worth 20*l.* each: the Mary of Trezzo, 3*l.* The deareft of Simon's works are his head of Thurloe, in gold, 12*l.*; his oval medal, in gold, upon Blake's victory at fea, 30*l.*: his trial piece, if brought to fale, would bring a larger fum. Queen Anne's medals in gold, intrinfically worth about 2*l.* 12*s.* 6*d.*, bear about 3*l.* a-piece. The filver, of about the fize of a crown-piece, will bring 10*s.* each; the copper from 5*s.* to 10*s.* The Scottifh coins are on a par with the Englifh, excepting that the gold fell higher. The fhilling of Mary, with the buft, is very rare, and brings 30*s.*; the half, 3*l.*; the ryal, 5*l.* 5*s.* The French teftoon of Francis and Mary brings 10*l.* 10*s.*; the Scottifh one of Mary and Henry would bring 50*l.*; as would alfo the medal of James IV. The coronation medal of Francis and Mary is worth 20*l.* Briot's coronation medal in gold fold only for 2*l.* 2*s.* at Dr. Mead's fale in 1755, but would now bring 20*l.* The Englifh coins ftruck in Ireland, or appropriated to that kingdom, are moftly of the fame price as the other Englifh coins. The St. Patrick's halfpence and farthings are rather fcarce. The gun-money of James II. is quite common. The rare crown of white metal brings about 4*l.* All other Irifh coins are very common. See the Appendix to Pinkerton's Effay.

MEDALS, *Counterfeit*, are forged imitations of ancient coins; the art of doing which is faid to have arifen at the beginning of the 16th century, and has fince prevailed to an aftonifhing degree. Thefe counterfeit medals are diftributed into fix claffes: 1. Medals known to be modern imitations of the ancient; but which being executed by mafters, fuch as the Paduan, &c. have their value. 2. Medals caft from thefe modern mafterly imitations. 3. Medals caft in moulds taken from the antique. 4. Ancient medals which are retouched, and the obverfes or reverfes altered. 5. Medals which are impreffed with new devices, or which are foldered. 6. Counterfeit medals which have clefts, or which are plated. For the method of diftinguifhing thefe counterfeits from the true, in which the poffeffors or purchafers of medals are particularly interefted, we refer to Mr. Pinkerton's Effay, vol. ii. p. 167, &c.

MEDALS, for the manner of ftriking, fee COINAGE.

MEDALS, *Academy of*. See ACADEMY.

MEDALS, *Cabinet of*, may be divided into three diftinct fizes: 1. The large and complete cabinet, containing, or intended to contain, every iffue of the mint, in every age and every country. The late king of France had the moft richly furnifhed cabinet of this kind in exiftence, and which is calculated to have coft near 100,000*l.* fterling. That of the late Dr. Hunter was, perhaps, one of the beft private cabinets ever formed in this ftyle; and coft about 21,000*l.* 2. The fmaller cabinet, the collector of which, confining himfelf to the forming of five or fix fequences, as of middle and fmall Roman brafs only, of Englifh pennies, or of groats, or any other particular feriefes, confiders other medals as out of his line of collecting, though he may purchafe a few defolate ones, or fuch as belong to other fets, in order to give variety to his collection. Such a cabinet may incur an expence of from 200*l.* or 300*l.* to 1000*l.* 3. The leaft cabinet, or cafket of medals, which may include all little collections of coins, from 100 to 1000 or 2000. In this not above one or two fequences can well be formed; but the amateur pleafes his fancy by the mifcellaneous infertion of any article which curiofity or other motives may incline

cline him to procure. In the formation of the large cabinet, it is to be obferved, that in the grand divifion of ancient coins, as diftinct from the modern, the Greek medals, of every denomination, can never be arranged by the metals, or fizes, like the Roman; for no feries of any one metal, or fize, can be found of this clafs in the moft opulent cabinet. On this account the civic coins of all metals and fizes, are digefted in alphabetical order, and the monarchic in chronological. The fame rule is to be obferved in the Roman confular medals, which are arranged in alphabetical feries of the families, like thofe of the Greek cities. The proper divifions of a grand and complete cabinet, comprehending the part allotted to ancient coins, are ftated by Mr. Pinkerton as follows: 1. The coins of cities and free ftates, in alphabetical order; whether ufing Greek, Roman, Punic, Etrufcan, or Spanifh characters. 2. Kings in chronological feries, both as to foundation of empire and feniority of reign. 3. Heroes, heroines, and founders of empires, and of cities. 4. Other illuftrious men and women. 5. Roman *Afes*. 6. Coins of families, commonly called confular. 7. Imperial medallions. 8. Imperial gold. 9. Imperial *minimi*, of all metals. 10. Imperial filver. 11. Imperial firft brafs. 12. Second brafs. 13. Third brafs. 14. Colonial coins, which are all of brafs. 15. Greek cities under the emperors, of all metals and fizes. In a fmaller cabinet they may be put with the Roman, according to their metal and fize. Thofe without the emperor's head go to clafs 1, though ftruck in Roman times. 16. Egyptian coins ftruck under the Roman emperors, of all metals and fizes. They are moftly of a bafe metal, called by the French writers "potin," being a kind of pot-metal, or brittle brafs. 17. "Contorniati," or ticket medals. 18. Coins of Gothic princes, &c. infcribed with Roman characters. 19. Coins of fouthern nations, ufing unufual alphabets; as the Perfian, Punic, Etrufcan, Spanifh. 20. Coins of northern nations, ufing unufual characters; as the Runic and German.

In the modern part no feries can be found of copper that will go back above two centuries; but fequences of gold and of filver may be arranged of all the different empires, kingdoms, and ftates, fo far as their feveral coinages will allow. Thofe of England and France will be the moft perfect. Modern filver is commonly arranged in three fequences; the dollar fize, the groat fize, and the penny fize. The metals of each modern country ought of courfe to be feparated; though it is beft to arrange each fet in chronological order, whatever be their fize or the metal.

The formation of a cabinet of the fecond clafs will admit of obferving the directions for the former, fo far as this is meant to extend. But as it includes only a few complete fequences, either of ancient or mordern coins, fome particular inftructions may be neceffary. If, *e.g.* the collector means to form a feries of the large brafs, he will find the coins of four or five emperors fo fcarce as not to be attainable in that feries, even at any price. He muft, therefore, fupply their places with a middle brafs, as is allowed with regard to Otho even in the beft cabinets, there not being above three coins of that emperor in large brafs known in the world, whereas of the middle brafs two or three hundred may exift. If this be allowed in one inftance, why not in others? Why may not Tiberius or Pertinax appear in the middle brafs as well as Otho? In cabinets of the fecond clafs the collector may mingle the middle with the large brafs as he thinks proper; and in like manner the fmall with the middle. In the fmall fequences there can be no harm in his mixing gold, filver, and brafs, as chance or curiofity may lead him to purchafe any of thefe metals. In like manner, if, in the modern part of the fmaller cabinet, any coin of a feries is of high price, or of bad impreffion, there can be no impropriety in putting another of the fame reign which is cheaper, or better executed, though of a different denomination, and a little larger fize. In fhort, the collector has no rules, but in the Greek cities and Roman families to obferve alphabetical order, and chronology in every thing elfe. The management in a cafket of medals may be conducted by the obfervations already made upon thofe of the two higher defcriptions.

MEDALS, *Caft,* are thofe which are not ftruck, but caft in a mould.

MEDALS, *Contourniated.* See CONTOURNIATED.

MEDALS, *Covered* or *Plated,* are thofe which have only a thin filver leaf over the copper, but which are ftruck fo artfully, that the cheat does not appear without cutting them; thefe are the leaft fufpected.

MEDALS, *Countermarked,* are thofe which have marks cut either on the fide of the head, or of the reverfe. Thefe countermarks ferve to denote the change of their value; and this kind is much inquired for by the curious. See MEDALS, *fupra.*

MEDALS, *Dipt,* are ftruck of pure copper, and afterwards filvered. This is a contrivance that the curious have frequent recourfe to, in order to complete their filver fets.

MEDALS, *Grained* or *Indented,* are thofe whofe edges are cut, or notched like teeth, which is a fign of purity and antiquity. They are common among the confulars, but we have none later than Auguftus. There are feveral of them, however, among thofe of the kings of Syria.

MEDALS, *Impreffions* or *Cafts of.* A very eafy and elegant way of taking impreffions or cafts of medals and coins is this: melt a little ifinglafs glue, made with brandy, and pour it thinly over the medal, fo as to cover its whole furface; let it remain on for a day or two, till it is thoroughly dry and hardened, and then taking it off, it will be fine, clear, and hard as a piece of Mufcovy glafs, and will have a very elegant impreffion of the coin. In order to render the relief of the medal more apparent, a fmall quantity of carmine may be mixed with the melted ifinglafs; or the medal may be previoufly coated with leaf-gold by breathing on it, and then laying it on the leaf, which will by that means adhere to it; but the ufe of leaf-gold is apt to impair a little the fharpnefs of the impreffion. Impreffions of medals may be likewife taken in putty of the true kind, made of calx of tin and drying oil. Thefe may be formed in the moulds, previoufly taken in plaifter or fulphur; or moulds may be made in its own fubftance, like thofe of plaifter. Thefe impreffions will be very fharp and hard; but the greateft difadvantage attending them is their drying very flowly, and being liable in the mean time to be damaged.

Sulphur is fometimes ufed to take off impreffions of medals, coins, &c. The method is this: having made a ledge of clay about the work whofe impreffion is defired, and carefully oiled the whole, gently pour brimftone melted in a covered veffel, to prevent its firing, upon the metal. About the edge of this mould make a border of clay, as before, and lightly oil the internal furface of both; then gradually put into it, to the thicknefs of about a quarter of an inch, a mixture made up with calcined alabafter and water, to the confiftence of ftiff honey. This foon growing hard, may be taken out of the mould, and gives figures of the coin or medal. Boyle's Works, abr. vol. i. p. 151. A method fomewhat different is defcribed under the article BRIMSTONE.

The brittlenefs of fulphur is a great objection to this method, and the plaifter of Paris, which is often ufed for

taking

taking impressions, is too soft: however, a coat or layer of thin metal, formed over the plaister, would be a considerable defence. This is the cheapest and most convenient metal for this purpose: let thin tin-foil, such as is used for silvering looking-glasses, be laid over the medal or coin intended to be taken off, and then rubbed either with a brush, the point of a skewer, or a pin, till it has received perfectly the impression of the medal; then pare off the tin-foil round the edge of the medal, till it is brought to the same circumference; afterwards the medal must be reversed, and the tin-foil will drop off into a chip-box, or mould ready to receive it; the concave side of the foil, or that which is laid on the face of the medal, being uppermost; upon this pour plaister of Paris, made in the usual manner, and when dry the cast figure may be taken out of the box or mould, with the tin-foil sticking on the plaister, the convex side being now uppermost, in which position it is to be kept in the cabinet after it becomes dry. To have an impression very perfect, the thinnest tin-foil should be made use of. The impressions taken in this manner almost equal silver medals in beauty, and are very durable. If the box or mould be rather larger than the impression of tin-foil, the plaister, when poured on, runs round its edges, and forms a kind of white frame, or circular border round the foil, whence the new made medal appears more neat and beautiful. If this tin-foil is gilt with gold-leaf, by means of thin isinglass glue, the medal will resemble gold.

Casts of medals may be made likewise with iron, prepared in the following manner: Take any iron bar or piece of a similar form; and having heated it red-hot, hold it over a vessel containing water, touch it very slightly with a roll of sulphur, which will immediately dissolve it, and make it fall in drops into the water. When a sufficient quantity of iron is thus dissolved, pour the water out of the vessel, and pick out the drops formed by the melted iron from those of the sulphur which contain little or no iron, and will be distinguishable from the others by their colour and weight. The iron will, by these means, be rendered so fusible, that it will run with less heat than is required to melt lead; and may be employed for making casts of medals, and many other such purposes, with great convenience and advantage.

We have an easy method of procuring the true impression or figure of medals and coins, by Mr. Barker in the Philos. Trans. N° 472. sect. 13. vol. xliii. p. 77.

Take a perfect and sharp impression on the finest black sealing-wax, of the coin or medal you desire. Cut away the wax round the edges of the impression; then with a preparation of gum-water, of the colour you would have the picture, spread the paint upon the wax impression with a small hair-pencil, observing to work it into all the sinking or hollow places, these being the rising parts of the medal; and the colouring must be carefully taken from the other parts with a wet finger. Then take a piece of very thin post-paper, a little larger than the medal, and moisten it quite through. Place it on the wax impression, and on the back of the paper lay three or four pieces of thick woollen cloth or flannel of about the same size. The impression, with its coverings, should be placed between two smooth iron plates, about two inches square, and one-tenth of an inch thick.

These must be carefully put into a small press, made of two plates of iron, about five inches and a half long, one inch and a half wide, and half an inch in thickness, having a couple of long male screws running through them, with a turning female screw on each, to force the plates together. These being brought evenly together by means of the screws, will take off a true and fair picture of the medal; which, if any deficiencies should appear, may easily be repaired with a hair-pencil or pen, dipped in the colour made use of.

If a relievo only be desired, nothing is necessary but to take a piece of card, or white paste-board, well soaked in water, then placing it on the wax-mould, without any colouring, and let it remain in the press for a few minutes, a good figure will be obtained.

This method of taking off medals, &c. is convenient, and seems much more so than the several inventions usually practised in sulphur, plaister of Paris, paper, &c. wherein a mould must be formed, either of clay, horn, plaister, or other materials, which requires time and trouble.

Some take impressions on paper from the medals themselves, by passing them through the rolling-press, and colouring them afterwards; but this is not only more difficult, but does great injury to the medals, by impairing the sharpness of their most delicate and expressive strokes: whereas wax does not hurt the finest medal in the least degree; and though a brittle substance, yet it effectually resists the force of a downright pressure.

Red seems the best colouring, and therefore black wax is directed to be used; but if the pictures are chosen in black and white, to resemble copper-plates, the wax should be red; for the wax and paint ought to be of different colours, in order to distinguish when the colour is laid on properly, or rightly cleared away.

The substance of medals, being metalline, is liable to be corroded; and the figures being raised, are also liable to be effaced by friction. Hence it is rare to find any perfectly preserved. Gems are not subject to these inconveniencies. See GEM.

MEDALS, *Mutilated*, are those that are not entire, or are much defaced.

MEDALS, *Redintegrated*, are those wherein we find the letters rest, which shew that they have been restored by the emperors.

MEDAL, *Repairing a*. See REPAIRING.

MEDALS, *Restitution of*. See RESTITUTION.

MEDALS, *Votive*. See VOTIVE.

MEDALS *without Reverse*. See REVERSE.

MEDALETS, a name given by Mr. Pinkerton to those small coins or missilia, scattered among the people on solemn occasions, those struck for the slaves in the Saturnalia, private counters for gaming, tickets for baths and feasts, tokens in copper and lead, and the like. Baudelot, in his curious and entertaining work, "L'Utilite des Voyages," has produced many singular specimens of medalets; for some of which see Pinkerton's Essay on Medals, vol. i. p. 227, &c.

MEDALLION, or MEDALION, a medal of extraordinary size.

The word is formed from the French *medaillon*, or Italian *medaglion*, which signify the same, or a large medal; and which were originally formed from *metalliones*, a name by which these pieces are frequently called in ancient Latin writers.

Medallions were never any current coins, as some medals probably were: they were struck purely to serve as public monuments, or to be presented by the emperor to his friends, and by the mint-makers to the emperor, as specimens of fine workmanship.

They were struck upon the commencement of the reign of a new emperor, and other solemn occasions; and frequently, the Greek medallions in particular, as monuments of gratitude, or of flattery. Sometimes they were trial or pattern-pieces, "testimonia probatæ monetæ;" and such abound after the reign of Maximian, with the "Tres Monetæ"

netæ" on the reverse. It is observed, that all Roman pieces in gold, exceeding the denarius aureus; all in silver, superior to the denarius; and all in brass, superior to the sestertius, or what the medallists term large brass, are comprehended under the description of medallions. Mr. Pinkerton, however, thinks that the gold medallions, weighing two, three, or four aurei only, passed in currency as the Greek gold didrachms, tridrachms, or tetradrachms, according to their size. The like may be said of the silver, which are commonly of the value of a Greek tetradrachm, which went in currency for four denarii. But it is not of much moment whether any of the pieces called medallions passed as coin with the ancients; it is sufficient to know what kind of coins passed under that denomination. The brass medallions, which are the largest, are commonly of the most exquisite workmanship, and uncommon device. Many of them are composed of two sorts of metal, the centre being copper, with a ring of brass around it, or the contrary. The inscription of such sometimes bites upon both metals, and at other times runs upon one. Medallions of this kind are inimitable, and of undoubted antiquity. Medallions from the time of Julius to that of Hadrian are very uncommon, and of very high price; from Hadrian to the close of the western empire they are, generally speaking, less rare. The types of the Roman medallions are often repeated upon common coin: hence they appear of less importance than the Greek, impressions of which are frequently most uncommon, and no where else to be found. A remarkable distinction between the Greek and Roman medallions lies in their different thickness; the Roman being often three or four lines thick, while the others seldom exceed one. By the Greek medallions we mean those struck in the imperial periods; for few Greek medallions are found prior to the emperors of Rome. Of Greek medallions, preceding the Roman empire, few are known. Some occur of Rhodes; and there is a fine one struck at Syracuse, upon the defeat of Icetas by Timoleon. The medallion is of silver, with the head of Ceres upon one side, and upon the other a female figure, perhaps representing Sicily or Syracuse, in a car, a victory crowning her, and spoils in the exergue. Its workmanship is fine, but not eqnal to the gold coin of the same Icetas, struck at Syracuse, ΕΠΙ ΙΚΕΤΑ, under Icetas, which is a perfect gem, surpassing all description. Syracuse also affords a most remarkable medallion on another great occasion. The only one perhaps existing formerly belonged to Dr. Combe, and was engraven by his order. It is exquisitely wrought, in high relief, and perfect preservation; of copper, and about two inches in diameter. Upon one side is a female head, covered with a helmet, on which is a caduceus, and ROMA. Upon the other is a man's head, with a helmet wreathed with laurel, and M. M. Dr. Combe thinks this fine piece, now in Dr. Hunter's cabinet, was struck by Syracuse, in honour of Marcus Claudius Marcellus, who besieged and took that city, 210 years B.C. This medallion is most remarkable for its being unique; for its beauty, for its preservation, and for the portrait of this great man. These are perhaps the only Greek medallions prior to the Roman empire. Many Roman medallions have S. C., as being struck by order of the senate; others have not, as being by order of the emperor. Of Augustus a noble medallion was found in Herculaneum, and Khell published a dissertation upon it. There are medallions of Augustus and Tiberius, struck in Spain; and one of Livia, at Patræ in Achaia: one in brass of Antony and Cleopatra; reverse, two figures in a car, drawn by sea-horses. Of Tiberius there are many, and also of Claudius. There are also some of Agrippina, Nero, Galba, Vespasian, and Domitian. Those of Trajan and Hadrian have generally a very broad rim, beyond the legend, with indented circles; and of Hadrian, Baldini gives no less than 47. There are fine medallions of Commodus, and his famous mistress Marcia; their heads are joined, and she wears a helmet. One of Pertinax bears, for reverse, that emperor sacrificing, with VOTIS DECENNALIBUS. There are many of Severus, Gordian III., and Philip; afterwards they are numerous of Gallus, Valerian, Gallienus, Aurelian, Probus, Diocletian, Maximian I., Constantius I., Constantinus I. and II., Constans, and Constantius II. Of other emperors they are scarcer. In Dr. Hunter's cabinet, among many others, there is one of Otacilia. The Greek medallions of Roman emperors are far more numerous than the Roman. All medallions, one or two instances excepted, are very rare, and of princely purchase. Even in the richest cabinets, 20 or 30 medallions are esteemed of great weight. In the 17th century, however, queen Christina was so fortunate as to procure about 300; and the king of France's cabinet was possessed of about 1200 medallions. Dr. Hunter's cabinet contains about 400, exclusive of Egyptian. There are also Latin medallions, of a size between first and second brass, or larger than our half-crown, easily distinguishable by their thickness, and uncommon neatness and manner. These are, by Italian medallists, called "Medaglioncini," or little medallions. In Dr. Hunter's collection is a fine one of Alexander Severus and Julia Mammæa, face to face; reverse their figures, with FELICITAS TEMPORVM. Pinkerton's Essay on Medals, vol. i.

MEDALLION, in *Architecture*, is any circular tablet on which are imbossed figures or bustos.

MEDAMA, in *Geography*, a town of the island of Ceylon; 16 miles N. of Candi.

MEDAMPE, a town of the island of Ceylon; 36 miles N. of Columbo.

MEDANIPEK, a town of Servia, on the river Ipek; 22 miles S.W. of Orsova.

MEDARD, ST., a town of France, in the department of the Lot; 8 miles N.W. of Cahors.

MEDAUAR, a town of Arabia, in the province of Yemen; 28 miles N.W. of Dsjebi.

MEDAUSO, a town of Africa, in the country of Bergoo; 150 miles S.W. of Wara.

MEDE, JOSEPH, in *Biography*, a learned divine, was born in 1586, at Berden in Essex, and in 1602 entered of Christ's college, Cambridge, where he studied with intense application, was chosen fellow, and proceeded to his degree of bachelor in divinity. He refused several preferments, particularly the provostship of Trinity college, Dublin, which was repeatedly offered him by archbishop Usher. He died in 1638. His works have been collected into one volume folio. The principal is his Commentary on the Apocalypse; in explaining which, his plan has been followed by bishop Newton, and a number of other great divines. Biog. Brit.

MEDEA, in *Geography*, a town of Algiers, in the province of Titterie, surrounded with mud walls, anciently "Lamida;" 32 miles S.W. of Algiers. N. lat. 26° 5'. E. long. 2° 50'.

MEDEA, *El*, *Mehdia*, or *Mehedia*, a town of Africa, in the kingdom of Tunis, on a peninsula, on the east coast, formerly a place of great strength and importance. The port, which was an area of nearly 100 yards square, lies within the walls of the city, with its mouth opening towards Cap-oudia; but at present not capable of receiving the smallest vessel; 80 miles S. of Tunis. N. lat. 35° 20'. E. long. 11°.

MEDEBACH,

MEDEBACH, a town of Westphalia; 32 miles W. of Cassel. N. lat. 51° 10′. E. long. 8° 48′.

MEDELLIN, a town of Spain, in Estramadura, on the Guadiana, being the native place of Fernando Cortez. It is an ancient town, having been founded by Q. C. Metellus, the Roman consul, and called by him "Metellinum;" 13 miles S.E. of Merida. N. lat. 38° 43′. W. long. 5° 47′.—Also, a town of Mexico, in the province of Tlascala, 25 miles S. of Vera Cruz, on a river of the same name, which runs into the gulf of Mexico, N. lat. 19°.

MEDELPAD, a province of Sweden, in the division called Nordland, bounded on the north-east by Angermanland, on the east by the gulf of Bothnia, on the south-west by Helsingland, and on the north-west by Jamtland, or north by the river Indal, and south by the Niurunda; from 13 to 20 leagues from north to south, and upwards of 30 from west to east. This province, though mountainous and woody, contains several vallies of meadow and arable land, interspersed with rivers and lakes, which yield abundance of fish. The grain, which is sown here about Whitsuntide, produces corn that ripens in ten weeks; and it is sufficient to supply the inhabitants. The forests abound with game of all sorts, elks, rein-deers, beavers, martins, weasels, lynxes, foxes, and wild fowl. The inhabitants have plenty of cattle, and traffic in timber, hops, flax, hemp, butter, fruits, and dried fish. The only sea-port is Sundswall, which is a mean though trading town, situated in a dry and sandy tract, near the bottom of a bay, with a convenient port. This province lies in N. lat. 62° 30′.

MEDELSHEIM, a town of France, in the department of Mont-Tonnerre, and chief place of a canton, in the district of Deux-Ponts. The place contains 338, and the canton 4521 inhabitants, in 15 communes.

MEDEM, a town of Arabia, in the province of Yemen, and the Imam's dominions: it is the capital of Hamdan, and the residence of a schiech; 10 miles N.N.W. of Sana.

MEDEMBLICK, a sea-port town of Holland, at the entrance into the Zuyder see, small though ancient, and, before Enckhuysen and Hoorn were built, the capital of North Holland. The inhabitants trade chiefly in timber, which they bring from Norway, and other northern parts of Europe. Its vicinity abounds with rich pastures. As the land is here lower than the waters, it requires very strong dykes and dams to defend it from the fury of the waves; 26 miles N. of Amsterdam. N. lat. 52° 29′. E. long. 4° 58′.

MEDEN, a river of the Isle of Wight, which runs into the sea between East and West Cowes, but is navigable for small vessels to Newport.—Also, a river, which rises from a lake in the duchy of Bremen, and discharges itself into the Elbe, two miles below Otterndorf, N. lat. 53° 55′. E. long. 8° 44′.

MEDENA, in *Surgery*, a name given by Paracelsus to a particular class of ulcers.

MEDENAM, in *Geography*, a town of Prussia, in the province of Samland; 12 miles N.W. of Konigsberg.

MEDEOLA, in *Botany*, is the Linnæan name of this genus, thought by Professor Martyn to be "a diminutive of *Medea*, the famous sorceress of antiquity." Linn. Gen. 179. Schreb. 240. Willd. Sp. Pl. v. 2. 270. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 327. Michaux. Boreal-Amer. v. 1. 214. Juss. 42. Lamarck Illustr. t. 266.—Class and order, *Hexandria Trigynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* Perianth none. *Cor.* inferior, deeply cloven into six, ovate-oblong, equal, spreading, revolute segments. *Stam.* Filaments six, awl-shaped, the length of the corolla; anthers incumbent. *Pist.* Germens three, corniculate, ending in the styles; stigmas recurved, thickish. *Peric.* Berry roundish, trifid, three-celled. *Seeds* solitary, heart-shaped.

Eff. Ch. Calyx none. Corolla deeply six-cleft, revolute. Berry three-seeded.

Obs. Linnæus remarks that *M. virginiana*, which he received from the celebrated Gronovius, had four petals; and Jussieu further says, that the same species having verticillate leaves, and the habit of *Trillium* or *Paris*, is very nearly akin to those genera. *Jacquinia ruscifolia* was originally considered by Linnæus as a *Medeola*.

1. M. *virginiana*. Virginian Medeola, or Indian Cucumber. Linn. Sp. Pl. 483. Sims in Bot. Mag. t. 1316.—Leaves verticillate.—A native of Virginia, flowering in June. Michaux says that it is common in moist woods throughout the whole of North America. *Root* tuberous and fibrous. *Stem* scarcely a foot high, simple, erect or somewhat scandent, about the thickness of a quill, covered with a reflexed, hairy down. *Leaves* whorled, from six to eight in the upper and three in the lower whorl, ovate, pointed. *Flowers* on pendent stalks, greenish-yellow, with purple filaments, without smell. Its root, which is eaten by the Indians, is said to resemble the Cucumber in flavour, and hence the English name.

2. M. *asparagoides*. Broad-leaved shrubby Medeola. Linn. Sp. Pl. 484. (Asparagus africanus scandens, myrti folio; Til. Pis. t. 12. f. 1.)—Leaves alternate, ovate, unequally heart-shaped at the base.—A native of the Cape of Good Hope. It flowers during the greater part of the winter, and was cultivated in 1702 by the duchess of Beaufort. *Root* composed of several oblong knobs, uniting at the top like that of a *Ranunculus*. *Stems* round, twining, branched, several feet long. *Leaves* sessile, acutely pointed, light-green beneath, but dark above. *Flowers* one or two on a stalk, dull white. Michaux is of opinion that *M. asparagoides* should be referred to another genus, and Mr. Gawler says, in the Botanical Magazine, that the following, *M. angustifolia*, together with this, should be excluded from *Medeola*.

3. M. *angustifolia*. Narrow-leaved Medeola. Willd. n. 3. (Asparagus africanus scandens, myrti folio angustiore; Til. Pis. t. 12. f. 2.)—Leaves alternate, lanceolate.—A native also of the Cape, flowering in the early spring. *Root* similar to the preceding. *Stalks* weaker, not so much branched, but climbing higher. *Leaves* long and narrow, of a greyish colour. *Flowers* lateral, two or three on a stalk, of an herbaceous white appearance.

Professor Martyn observes that "the flowers of these two latter species making no great appearance, the plants are not preserved for their beauty; but as their stalks are climbing, and their leaves are in full vigour in winter, during that season they add to the variety of the green-house."

Medeola, in *Gardening*, comprises plants of the herbaceous climbing kind, of which the species cultivated are the Virginian medeola (M. virginiana); the broad-leaved shrubby medeola (M. asparagoides); and the narrow-leaved medeola (M. angustifolia).

Method of Culture.—These sorts of plants may be increased by planting off-sets, taken from the roots in the summer season, about July, in pots filled with good, rich, light mould, remaining in the open air till autumn, when they should be removed into the green or hot-house; but the latter, when intended to fruit. While the plants have a vigorous growth, they should be frequently refreshed with water; but, as the stems decay, very little, especially when placed in an eastern aspect.

The

The fecond and third forts may alfo be raifed from feed; but they commonly remain long in the earth before they come up.

The firft fort is fufficiently hardy to ftand in the open air during the winter feafon.

They all afford variety in green-houfe and ftove collections, in the winter feafon, among other plants.

MEDERA, or MEDRA, in *Geography*, a town of Africa, in the kingdom of Bournou.

MEDES, *Empire of.* See EMPIRE and MEDIA.

MEDFIELD, in *Geography*, a townfhip in Norfolk county, Maffachufetts; 20 miles S.W. of Bofton; incorporated in 1650, and containing 745 inhabitants.

MEDFORD, a pleafant, thriving, compact town in Middlefex county, Maffachufetts, fituated on Myftick river, three miles from its mouth, and four miles N. of Bofton. The river is navigable for fmall veffels to this place, where it meets the Middlefex canal. The townfhip was incorporated in 1630, and contains 1114 induftrious inhabitants. Here are four diftilleries, which have diftilled in one year 252,450 gallons of rum. About four millions of bricks are made annually in this town, moft of which are conveyed to Bofton.

MEDHERAM, a town of Africa, in the kingdom of Fezzan; 330 miles S.S.E. of Mourzouk.

MEDHERAM *Iza*, a town of Africa, in the defert of Berdoa. N. lat. 24° 35'. E. long. 16° 24'.

MEDHRA, among Hindoo metaphyficians and mythologifts, is a name of the *Yoni;* which fee.

MEDIA, or, as it was fometimes called, *Medena*, in *Ancient Geography*, an extenfive country of Afia, and the feat of a powerful empire, bounded, according to Ptolemy, on the north by part of the Cafpian and Hyrcanian fea, on the fouth by Perfia, Sufiana, and Affyria, on the eaft by Parthia and Hyrcania, and on the weft by Armenia Major. In ancient times it was divided into feveral provinces, which by a later arrangement were reduced to two, the one called "Media Magna," and the other "Media Atropatra," or fimply *Atropatene;* which fee. The cities of note in this latter part of Media were Gaza, the metropolis (which fee); Sanina, fituated between the Araxes and the Cambyfes; Fazina, between the Cambyfes and the Cyrus; and Cyropolis, between the Cyrus and the Amardus. This tract was inhabited by the Cadufians and Cafpians, a barbarous and inhuman race, originally fprung from the Scythians.

Media Magna was bounded by Perfis, Parthia, Hyrcania, the Hyrcanian fea, and Atropatene. The moft remarkable cities in it were Ecbatana, Laodicea, Apamea, Rega or Regaia, and Arfacia. This part of Media was inhabited by the Carduchians, Marandæans, Gelians, Syro-Medians, Margafians, &c. The mountains of this country, according to Ptolemy and Strabo, are Choatra, parting Media from Affyria; Xagrus, dividing it from the fame Affyria on the eaft, which, according to Polybius, was 100 cubits high; Parachoatra, placed by Ptolemy on the borders towards Perfia, and by Strabo on the confines of Media, Hyrcania, and Parthia. To thefe, which are the boundaries between Media and the adjacent provinces, may be added the Orontes, the Jafonius, and the Coronus, in the interior of the country. The rivers of note, according to Ptolemy, are the Straton, the Amardus, the Cyrus, and the Cambyfes; properly belonging to the provinces of Ghilan and Mazanderan, and not to Media Proper, as defcribed by the ancients. The northern parts of Media, lying between the Cafpian mountains and the fea, are very cold and barren: the prefent inhabitants make their bread of dried almonds, and their drink of the juice of certain herbs. The fnow lies on the mountains for nine months in the year. But the fouthern parts produce all forts of grain, and neceffaries of life, and are fo pleafant, that the country adjoining to Tauris, probably the ancient Ecbatana, is called the garden of Perfia. It has large plains, one of which was called Nyfa, and was famous for its numerous ftuds of horfes, that were kept in it for the ufe of the Perfian monarchs. The climate of Media is various: that part which lies between the mountains and fea is cold and fwampy, and fubject to vapours exhaling from the Cafpian fea; but the provinces that are more remote from the fea, enjoy a very falubrious air, though liable to heavy rains and violent ftorms, efpecially in the fpring and autumn. In the neighbourhood of Tauris, it is faid that 60 different kinds of grapes, of exquifite flavour, have been found.

The Medes are faid to have fprung from Madai, the third fon of Japhet; and in procefs of time feveral perfons from the adjacent countries fettled here, on account of the fertility of the foil, and gave rife to the various tribes into which thefe people were anciently divided. Their government was originally monarchical, and they feem to have had their own kings in the earlieft times. They were firft brought under the Affyrian yoke by Pul, faid to be the founder of that monarchy, or by his immediate fucceffor Tiglath-Pilefer. In the reign of Sennacherib they fhook off this yoke, and fell into anarchy until the reign of Dejoces. Their kings after the revolt were quite abfolute, and controuled by no law. The Medes were once a very warlike people, but in procefs of time became one of the moft effeminate nations of Afia. They ufed the fame armour with the Perfians, whom, it is faid, they inftructed in the art of war; and it is likewife afferted, that they firft introduced luxury into Perfia, which ultimately occafioned the downfal of that empire. Polygamy was fo far from being difreputable among them, that they were bound by law to maintain, at leaft, feven wives, and thofe women were regarded with contempt, who maintained fewer than five hufbands. In war they fmeared their arrows with a bituminous liquor called naphta; fo that when the arrows were fet on fire and fhot from a flack bow, they burnt the flefh with fuch violence that water ferved to increafe rather than to extinguifh the flame. They are faid likewife to have bred a number of large dogs, to whom they threw the bodies of their friends, parents, and relations, when at the point of death, confidering it as difhonourable to die in their beds, or be laid in the ground. Some writers charge the Medes with being the firft who made eunuchs; but others impute this execrable practice to the Perfians. With the Medes originate the cuftom of confirming alliances with the blood of the contracting parties, which afterwards prevailed among all the eaftern nations, even in the Roman times. When they concluded alliances, they tied together, with a hard bandage, the thumbs of their right hands, until the blood ftarting to the extremities was, by a flight cut, difcharged. This they mutually fucked, and a league thus confirmed was efteemed moft awful, as myfterioufly folemnized with the blood of the parties. The laws and religion of the Medes were much the fame with thofe of the Perfians. (See PERSIA.) When a law was once enacted, it was not in the king's power to repeal it, or to reverfe a decree he had once made; whence the laws of the Medes are, in the facred writings (Dan. vi. 8.) called unchangeable. Their kings were treated with great refpect; and whenever they appeared in public, they were attended by mufic, and numerous guards, confifting of the prime nobility; their wives, children, and concubines, forming part of their retinue, even when they headed their armies in the field. We are ignorant of their arts, learning, and trade; but this is known, that during

during the ſhort period of their monarchy, they ſeem to have applied their thoughts only to warlike exerciſes, *viz.* to horſemanſhip and archery, in which they ſurpaſſed all other nations; the Median horſe being no leſs celebrated by the ancients than the Perſian infantry in ſubſequent ages.

In detailing their hiſtory, we begin with Pul, or Tiglath-Pileſer, already mentioned, who firſt brought them under ſubjection. From the time of Pul, or Tiglath-Pileſer, who ſucceeded his father in the year 740 B.C, they remained ſubject to the Aſſyrians till about the latter end of the reign of Sennacherib, 710 B.C., when, emancipating themſelves from Aſſyrian bondage, they fell into a ſtate of anarchy. This circumſtance, as Herodotus informs us, gave Eſar-Haddon, or Aſſar-Hadon, who ſucceeded Sennacherib, an opportunity of reducing a great part of Media, if not the whole country, under ſubjection. This anarchy is ſuppoſed to have laſted one year; for Dejoces, called Arphaxad in the book of Judith, was killed by Saooduchius or Nebuchadonoſor, in the year 656. From the commencement of the reign of Dejoces to the deſtruction of Nineveh, 601 B.C., Media may properly be ſtyled a kingdom. From the deſtruction of Nineveh, we may therefore date the riſe of the empire of the Medes. (See EMPIRE.) Their empire laſted till the taking of Babylon; for we learn from Xenophon, that after the reduction of that city, Cyrus went to the king of the Medes at Ecbatana, and ſucceeded him in the kingdom. The empire of the Medes laſted 65 years, at the period in which the Perſian empire took riſe in Cyrus. Paſſing over the fabulous hiſtory of the Medes, we ſhall begin with the reign of Dejoces, who was choſen by them as their judge, and who, aſpiring to the ſovereign power, performed that office with the ſtricteſt regard to juſtice. Upon his reſignation of this office, licentiouſneſs prevailed, and it was found neceſſary to appoint a king; upon which Dejoces was named to the ſovereignty, and with univerſal applauſe placed upon the throne 710 B.C. As ſoon as he was elected king, and veſted with the ſupreme power, he threw off the maſk, and became a tyrant. Ecbatana was built and choſen for the royal reſidence, and a ſtately palace was erected for the ſovereign. Dejoces, having enacted various laws for the government of the kingdom, and having, in a conſiderable degree, civilized his unpoliſhed ſubjects, entertained thoughts of extending the limits of his new kingdom, and with this view he invaded Aſſyria. Nebuchadonoſor, however, at that time king of Aſſyria, met him in the plain of Ragau, and a battle enſued, in which the Medes were utterly defeated, and Dejoces was ſlain, after a reign, according to Herodotus, of 53 years. The Aſſyrian king, availing himſelf of his ſucceſs, reduced ſeveral cities of Media, and among the reſt Ecbatana, which he almoſt utterly deſtroyed. Dejoces was ſucceeded by his ſon Phraortes, 647 B.C., and, not ſatisfied with the kingdom of Media, he invaded Perſia, and is ſaid to have brought that nation under ſubjection to the Medes. Such is the account of Herodotus; but others aſcribe the conqueſt of Perſia, not to Phraortes, but to his ſon and ſucceſſor Cyaxares. Phraortes, however, ſubdued ſeveral neighbouring nations, and made himſelf maſter of almoſt all the Upper Aſia, lying between mount Taurus and the river Halys. Emboldened by his ſucceſs, he invaded Aſſyria, ſubdued a great part of the country, and even laid ſiege to Nineveh, the metropolis. Here he periſhed, with the greater part of his army, after having reigned 22 years. Upon the death of Phraortes, his ſon, Cyaxares I., a brave and enterpriſing prince, ſucceeded him, 625 B.C. Having well diſciplined his troops, and recovered the territories which the Aſſyrians had taken during the reigns of his father and grandfather, he marched againſt Nineveh, but after having laid cloſe ſiege to the city, he was obliged to retreat, and to employ his troops in the defence of his own kingdom, againſt a formidable army of Scythians, who, having driven the Cimmerians out of Europe, purſued their flying enemies, and were ready to enter Media. The two armies engaged, and the Medes were utterly routed. The conquerors overran, not only all Media, but the greater part of Upper Aſia, extending their conqueſts into Syria, as far as the confines of Egypt. Cyaxares, deſpairing of being able to overpower the Scythians by force, had recourſe to ſtratagem; and invited them to a general feaſt, which was prepared in every family. Each hoſt intoxicated his gueſt; and in that condition the Scythians were maſſacred, and the kingdom delivered from a long and cruel bondage. The Medes were afterwards engaged with the Lydians; and during the engagement there happened a total eclipſe of the ſun, ſaid to have been foretold by Thales the Mileſian. Both parties were terrified, and ſoon after concluded a peace by the mediation of Labynetus, that is Nebuchadnezzar, king of Babylon, and Syenneſis, king of Cilicia. This peace was confirmed by the marriage of Aryenis, the daughter of Halyattes, and Aſtyages, the eldeſt ſon of Cyaxares; and of this marriage was born in the enſuing year Cyaxares, who, in the book of Daniel (ch. v. 31.) is called Darius the Mede. Cyaxares, diſengaged from the Lydian war, reſumed the ſiege of Nineveh; and having formed a ſtrict alliance with Nebuchadnezzar, king of Babylon, they joined their forces, and took and deſtroyed the city. (606 B.C.) With this proſperous event commenced the great ſucceſſes of Nebuchadnezzar and Cyaxares; and thus was laid the foundation of the two collateral empires, as they may be called, of the Medes and Babylonians, which roſe on the ruins of the Aſſyrian monarchy. After the reduction of Nineveh, the two conquerors led the confederate army againſt Pharaoh-Necho, king of Egypt, who was defeated near the Euphrates, and compelled to reſign what he had formerly taken from the Aſſyrians. After this victory they reduced all Cœleſyria and Phœnice; then they invaded, and laid waſte Samaria, Galilee, and Scythopolis; and at laſt beſieged Jeruſalem, and took Jehoiakim priſoner. Nebuchadnezzar afterwards purſued his conqueſts in the weſt, and Cyaxares ſubdued the Aſſyrian provinces of Armenia, Pontus, and Cappadocia. Again uniting their forces, they reduced Perſia and Suriana, and accompliſhed the conqueſt of the Aſſyrian empire. The prophet Ezekiel (ch. xxxii. 22. &c.) enumerates the chief nations that were ſubdued and ſlaughtered by the two conquerors Cyaxares and Nebuchadnezzar.

Cyaxares, having thus erected the kingdom of Media into a powerful empire, and ſhared the new acquiſitions with his Babylonian ally, died in the 40th year of his reign, and was ſucceeded by his ſon Aſtyages, called in ſcripture Ahaſuerus. This prince had by Aryenis, already-mentioned, Cyaxares II., called in ſcripture Darius the Mede, who was 62 years of age when Belſhazzar was ſlain at the capture of Babylon. In the year when Cyaxares was born, Aſtyages gave his daughter Mandane, whom he had by a former wife, to Cambyſes, a Perſian; from which marriage ſprung Cyrus, the founder of the Perſian monarchy, and the reſtorer of the Jews to their country, their temple, and their former condition. (See CYRUS.) Aſtyages, after a reign of 35 years, was ſucceeded by his ſon Cyaxares, uncle to Cyrus, 560 B.C. Whilſt Cyaxares lived, Cyrus held the empire only in partnerſhip with him, though he had entirely acquired it by his own valour; but as Cyrus was entruſted with the command of the army, and the whole management of affairs, he alone was regarded as the ſupreme governor of the empire. From

Joſephus

Josephus we learn, that Cyaxares, or Darius the Mede, with his ally, Cyrus, destroyed the kingdom of Babylon. After the reduction of Babylon, Cyaxares, in concert with Cyrus, settled the affairs of their new empire, and divided it into 120 provinces. The governors of these provinces were under the direction of three presidents, of whom Daniel was appointed the chief. (See DANIEL.) From this time Media became a province of Persia. See EMPIRE and PERSIA.

MEDIANA, in *Anatomy*, median, a name given to certain veins of the upper extremity. These are the median veins of the fore-arm, occupying the middle of the limb, between the radius and the ulna. These divide at the elbow into two chief trunks, of which one joins the basilic, and the other the cephalic vein of the arm: they are named respectively, vena mediana basilica, and v. m. cephalica. See VEIN.

MEDIANA, in *Geography*, a town of Spain, in Arragon; 12 miles S.E. of Saragossa.

MEDIANÆ, *Columnæ*, in Vitruvius, are the columns in the middle of a portico, whose intercolumniation is to be larger than those of the columns.

MEDIANTE, *Fr.*, in *Music*, is the string or sound which divides the fifth of a key into two thirds, the one major, and the other minor; and it is their relative position which determines the key. When the major third is the lowest, that is to say, between the mediante and key note, the key is major, or with a sharp third; when the major third is uppermost, and the minor at the bottom, the mode or key is minor, or with a flat third above the base.

MEDIASTINUM, in *Anatomy*, the partition which divides the chest into the right and left halves. See LUNG.

MEDIATE, or INTERMEDIATE, a term of relation to two extremes, applied to a third, which is in the middle between them. See MEAN and MEDIUM.

Substance is a genus with regard to man; but between the two there are other mediate genusses, as body and animal.

Mediate stands opposed to immediate: thus when we say that God and man concur to the production of man; God is the *mediate* cause, man the *immediate*.

MEDIATE *Mode*. See MODE.

MEDIATIO, *Lat.*, MEDIATION, *Fr.*, in *Canto Fermo*, implies the middle of a chant, or the sound which terminates the first part of a verse in the psalms. The punctuation of the psalms in the English psalter, where a colon is constantly placed in the middle of a verse, and frequently when the sense requires not so long a pause, expresses this mediatio, or breath-place, marked out for those who chaunt the psalms in the cathedral service.

MEDIATOR, in *Theology*, is an appellation which belongs in a peculiar, appropriate, and eminent sense, to Jesus Christ, the instructor and saviour of mankind; accordingly, as the doctrine of mediator between God and man is a matter of pure revelation, the New Testament expresly asserts that "there is one God, and one mediator between God and man, the man Christ Jesus," 1 Tim. ii. 5. Divines, however, have differed in their sentiments with respect to the nature and extent of this office, and the mode of its accomplishment. In a general view of this subject, it is argued by bishop Butler in his "Analogy, &c." that the whole analogy of nature removes all imagined presumption against the general notion of a mediator between God and man; so that, as the visible government which God exercises over the world, is carried on by the instrumentality and mediation of subordinate beings, there is no sort of objection against the general notion of a mediator, considered as a doctrine of Christianity, or as an appointment in this dispensation; since we find by experience, that God does appoint mediators to be the instruments of good and evil to us, the instruments of his justice and mercy. He adds, that it is clearly contrary to all our notions of government, as well as to what is, in fact, the general constitution of nature, to suppose that doing well for the future should, in all cases, prevent all the judicial bad consequences of having done evil, or all the punishment annexed to disobedience. And though the efficacy of repentance itself alone, to prevent what mankind had rendered themselves obnoxious to, and recover what they had forfeited, is now insisted upon, in opposition to Christianity; yet, by the general prevalence of propitiatory sacrifices over the heathen world, this notion of repentance alone being sufficient to expiate guilt, appears to be contrary to the general sense of mankind. As there was, therefore, room for an interposition to avert the fatal consequences of vice, revelation affords us such representations of the compassion and goodness of God in the administration of the world, as to give us reason to expect such an interposition; and, moreover, it informs us, that an interposition of this kind has been mercifully provided, in order to prevent the destruction of the human kind. (See John, iii. 16.) As for the particular manner in which Christ interposed in the redemption of the world, or his office as *mediator*, in the largest sense, *between God and man*, it is, as the learned prelate conceives, thus represented to us in the scriptures: 1st. He was, by way of eminence, "the prophet that should come into the world" (John, vi. 14.) to declare the divine will. He published anew the law of nature, which men had corrupted, and the knowledge of which was, to a great degree, lost among them. He taught mankind, authoritatively, to "live soberly, righteously, and godlily in this present world," in expectation of the future judgment of God. He confirmed the truth of this moral system of nature, and gave us additional evidence of it; the evidence of testimony. He distinctly revealed the manner in which God would be worshipped, the efficacy of repentance, and the rewards and punishments of a future life. Thus he was a prophet in a sense in which no other ever was. To which is to be added, that he set us a perfect "example, that we should follow his steps." 2dly. He has a "kingdom which is not of this world." He founded a church, to be to mankind a standing memorial of religion, and invitation to it; which he promised to be with always, even to the end. He exercises an invisible government over it himself, and by his spirit; over that part of it which is militant here on earth, a government of discipline. (See Eph. iv. 12, 13.) Of this church, all persons scattered over the world, who live in obedience to his laws, are members. 3dly. Christ offered himself a propitiatory sacrifice, and made atonement for the sins of the world; which is mentioned last, in regard to what is objected against it. Sacrifices of expiation were commanded the Jews, and obtained amongst most other nations, from tradition, whose original probably was revelation. And they were continually repeated, both occasionally and at the returns of stated times; and made up great part of the external religion of mankind. "But now once in the end of the world Christ appeared to put away sin by the sacrifice of himself." (Heb. ix. 26.) And this sacrifice was, in the highest degree, and with the most extensive influence, of that efficacy for obtaining pardon of sin, which the heathens may be supposed to have thought their sacrifices to have been, and which the Jewish sacrifices really were in some degree, and with regard to some persons.

How and in what particular way it had this efficacy, there are not wanting persons who have endeavoured to explain: but we do not find that the scripture has explained it. We seem to be very much in the dark, concerning the manner in which the ancients understood atonement to be made, *i. e.* pardon

pardon to be obtained by ſacrifices. And if the ſcripture has, as ſurely it has, left this matter of the ſatisfaction of Chriſt myſterious, left ſomewhat in it unrevealed, all conjectures about it muſt be, if not evidently abſurd, yet at leaſt uncertain. Nor has any one reaſon to complain for want of farther information, unleſs he can ſhew his claim to it.

Some have endeavoured to explain the efficacy of what Chriſt has done and ſuffered for us, beyond what the ſcripture has authorized: others, probably becauſe they could not explain it, have been for taking it away, and confining his office as redeemer of the world to his inſtruction, example, and government of the church. Whereas the doctrine of the goſpel appears to be; not only that he taught the efficacy of repentance, but rendered it of the efficacy which it is, by what he did and ſuffered for us: that he obtained for us the benefit of having our repentance accepted unto eternal life: not only that he revealed to ſinners, that they were in a capacity of ſalvation, and how they might obtain it; but moreover that he put them into this capacity of ſalvation, by what he did and ſuffered for them; put us into a capacity of eſcaping future puniſhment, and obtaining future happineſs. And it is our wiſdom thankfully to accept the benefit, by performing the conditions upon which it is offered, on our part, without diſputing how it was procured, on his.

Another writer, *viz.* Mr. Tomkins, in his treatiſe entitled "Jeſus the Mediator between God and Man," ſeems to have entertained ſimilar views with thoſe of biſhop Butler concerning the mediation of Chriſt. The ſcripture, ſays this writer, expreſsly gives Chriſt the title of mediator (the one mediator): this will be allowed even by thoſe who underſtand it of his mediating on the part of God towards us, or of his being inveſted with a mediatorial kingdom, in conſequence of which he diſpenſes the favours of God to men. But this, in the judgment of the author to whom we now refer, is merely half of what the ſcripture deſigns, when it calls Chriſt the mediator; for he ſuppoſes this office to include what he doth or hath done on our behalf towards God. The apoſtle, he thinks, evidently and directly refers to this (1 Tim. ii. 5.) when he adds, "who gave himſelf a ranſom for us." If, then, it appears that Chriſt offered himſelf a ſacrifice; that he makes interceſſion for us; that he is ordained for us an high-prieſt in things pertaining to God; and that we are required to come unto God by him under this character: if theſe, and the like, are in the plain literal ſenſe the doctrine of the New Teſtament, none, he ſuppoſes, can make it matter of diſpute, whether the title of mediator hath not reſpect to theſe things, as well as to his acting on the behalf of God towards us: in confirmation of which it may be obſerved, that the term itſelf ſeems to imply a tranſacting with each party on the behalf of the other; according to the language of the apoſtle "a mediator is not of one." The object of the author in the treatiſe which we have cited, is to lay before the reader the declarations of ſcripture on the ſubjects above ſtated; or to ſhew that they repreſent what it was appointed for Chriſt to do on our behalf, and conſequently what he hath done, or now does for us, in order to our reconciliation with God. Another writer, after ſhewing that the general notion of a mediator is not at all repugnant to the moſt honourable ſentiments we can entertain of the mercy of God, ſtates the ſubſtance of what he conceives to be the true Chriſtian doctrine of a mediator in the following terms: *viz.* "that our bleſſed Saviour was appointed by the ſupreme authority of heaven and earth, to *reconcile* apoſtate and rebellious men to their offended maker and ſovereign, and to be the *diſtributor* of God's favour to mankind." He thinks, that there are ſeveral probabilities that incline us to believe, that our bleſſed Lord never expreſsly aſſumed to himſelf the title of mediator, during the time of his public miniſtry upon earth, and that it never was aſcribed to him till after his exaltation to regal dignity and power; and of courſe that the mediatorial character of Chriſt did not properly commence till after his reſurrection, when he had all power committed to him, and was conſtituted the *one Lord*, through whom are all things. Adverting to the death of Chriſt, as a prominent event in his hiſtory, he obſerves, that it was not intended to render the Deity propitious, *i. e.* willing to be reconciled to his creatures upon fit and honourable terms, becauſe it was propoſed by *himſelf*, and the whole uſe and efficacy of it ſprung from his appointing and declaring it to be an accepted ſacrifice, ſo that it muſt neceſſarily ſuppoſe him to have been antecedently propitious. The truth of the caſe in his opinion ſeems to be, that it was "an expedient originally proceeding from the mercy of God, and not the argument or motive, inducing him to be merciful. The great purpoſes, as this author ſtates them, which are evidently ſerved by the expreſs command of God to conſider the death of Chriſt under the notion and character of a ſacrifice, are thoſe which follow.

Firſt, that it might be a ſtanding memorial of God's being propitious, and inclined to pardon the ſins of men; and an enforcement of that fundamental principle of all religion, that he is a rewarder of them that diligently ſeek him: "A memorial coinciding with the almoſt univerſal ſentiment and practice of the world (among whom ſacrifices were eſteemed as an eſſential part of religion), and likely, upon that account, to have a more certain and powerful influence."—Secondly, that it might be a ſtanding memorial, likewiſe, of the evil and demerit of ſin; and, conſequently, a perpetual incentive to humility and repentance.—And, thirdly, it ſeems to have been wiſely appointed with this view likewiſe, *viz.* to ſuperſede the uſe of all future ſacrifices; which, extending even to human ſacrifices, had been the moſt depraved and unnatural branch of heathen ſuperſtition. And, therefore, that it might the better produce this effect, which was worthy the care of infinite wiſdom and goodneſs, we are expreſsly informed, that Jeſus Chriſt hath, by one offering, "perfected for ever them that are ſanctified." Heb. x. 14.

And, in the laſt place, "there is formed, by this conſtitution, a beautiful analogy in a very conſiderable and important point, between the ſettled methods of God's natural providence, and the extraordinary operations of his grace;" which perhaps may juſtly be eſteemed as one of the principal reaſons of it. Foſter's Sermons, vol. iv. ſerm. xvi. See Atonement.

Mediators *of Queſtions*, in our *Old Writers*, were ſix perſons authorized by ſtatute, who, upon any queſtion ariſing among merchants, relating to any unmercable wool, or undue packing, &c. might, before the mayor, or officers of the ſtaple, upon their oath, certify and ſettle the ſame; to whoſe order and determination therein, the parties concerned were to give entire credence, and ſubmit. 27 Ed. III. ſtat. 2. c. 24.

Mediators, Μεσαζοντες, under the emperors of Conſtantinople, officers of ſtate, who had the direction of all affairs tranſacted at court. Their chief, or preſident, was called *megas meſazon*, μεγας μεσαζων, and anſwered to the prime or grand viſier of the Turks. Hofm. Lex. in voc.

MEDICA, in *Botany*, an old name for ſome plants of the Trefoil or Lucerne family, which Tournefort has retained for the genus *Medicago* of Linnæus. It is ſuppoſed to be derived from Media, the native country of the plants to which it was applied. See Medicago.

Medica

Medica is alſo the Linnæan ſpecific name of the Citron, *Malus medica*, or Median Apple, of the old writers. See Citrus.

MEDICAGO, ſo called by Tournefort, from *Medica*, which is indeed the proper name of the plant, (μηδικη of Dioſcorides), and aroſe from its having been introduced into Greece by the Medes, during the Perſian war in the time of Darius Hyſtaſpes. This name being reſtrained by Tournefort to a few ſpecies with a flat, not ſpiral, legume, he calls the very numerous ones in which that part is more or leſs convoluted, or ſpiral, *Medicago*, as reſembling, or approaching to, his *Medica*. Both tribes are united under the above appellation by Linnæus. The original *Medica* of the ancients, which was a valuable fodder, or, in the modern phraſe, *artificial graſs*, is probably one of the genus; though we cannot determine which, and it may poſſibly be ſome *Trifolium*, or perhaps a *Trigonella*. Lucern, Medick, or Snail Trefoil. Linn. Gen. 389. Schreb. 510. Willd. Sp. Pl. v. 3. 1403. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 795. Ait. Hort. Kew. ed. 1. v. 3. 96. Juſſ. 356. Lamarck Illuſtr. t. 612. Gærtn. t. 155. (Cochleata; Riv. Tetrap. Irr. t. 88. Falcata; ibid. t. 84, 85. 87.)—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Char. *Cal.* Perianth inferior, of one leaf, ſtraight, cylindrical, ſomewhat bell-ſhaped, divided about half way down into five pointed, nearly equal, ſegments. *Cor.* papilionaceous. Standard ovate, undivided, inflexed at its edges, the whole reflexed. Wings ovate-oblong, affixed to the appendages of the keel, cohering by their edges within it. Keel oblong, cloven, ſpreading, obtuſe, bent down by the piſtil, and divaricating from the ſtandard. *Stam.* Filaments in two ſets, united almoſt to the top; anthers ſmall. *Piſt.* Germen ſtalked, oblong, incurved, compreſſed, enfolded by the filaments, ſtarting from the keel, and forcing back the ſtandard, terminating in a ſhort, awl-ſhaped, nearly ſtraight, *ſtyle; ſtigma* terminal, minute. *Peric.* Legume compreſſed, long, inflexed. *Seeds* ſeveral, kidney-ſhaped or angular.

Obſ. The *Cochleatæ* of Rivinus have a ſpirally convoluted legume; his *Falcatæ* a curved, or ſickle-ſhaped one.

Eſſ. Ch. Legume compreſſed, ſpiral, forcing back the keel of the corolla from its ſtandard.

The lateſt edition of Linnæus enumerates but ten ſpecies of *Medicago*, becauſe he always confounded, under his *M. polymorpha*, a numerous tribe, which, though they generally accord very nearly in herbage, differ too widely and conſtantly in their fruit to be eſteemed mere varieties of one ſpecies. Willdenow, following Gærtner, has diſtinguiſhed them all, and has even added ſeveral new ones, making all together 37. He has perhaps gone too far, and the ſubject appears to demand reviſion, which we ſhall here attempt.—*Medicago virginica*, Linn. Sp. Pl. 1096, is ſuppoſed to be the ſame plant as *Hedyſarum fruteſcens*, and is therefore omitted here. On this point however the Linnæan herbarium affords no information.

* *Legumes lunate, ſomewhat twiſted.*

1. M. *arborea*. Tree Medick, or Moon Trefoil. Linn. Sp. Pl. 1096. (Cytiſus ſeptimus cornutus; Ger. em. 1305.)—Legumes lunate, entire at the margin. Stem arboreſcent.—Native of rocky places in various parts of Greece and the Archipelago, as well as about Naples, flowering in the early ſpring. It is with us a hardy green-houſe ſhrub. *Stem* buſhy. *Leaves* ternate, on long ſtalks; their leaflets inverſely heart-ſhaped, hoary and ſilky beneath, like all the ſtalks. *Flowers* in axillary, ſtalked heads, or very ſhort cluſters, of a full yellow. *Legume* reticulated, making ſcarcely more than one complete turn.—This ſhrub has been ſhewn by M. Amoureux in the *Mem. de la Soc. d'Agriculture de Paris*, for 1787, part 2d, to be the real *Cytiſus* of Virgil, celebrated by him for cauſing cows to yield abundance of milk, while its flowers are grateful to goats and to bees.

2. M. *radiata*. Radiated Medick. Gærtn. f. 5. (Lunaria radiata italorum; Lob. Ic. v. 2. 38. Trifolium ſiliquâ lunatâ; Ger. em. 1207.)—Legume kidney-ſhaped, toothed at the edge. Leaves ternate.—Native of Italy. *Root* annual. *Stem* erect, more or leſs branched from the bottom, a ſpan high. *Leaves* ſtalked, ternate, obovate, ſharply toothed, ſomewhat hairy. *Flowers* ſmall, yellow, two or three on each axillary ſtalk. *Calyx* hairy. *Legumes* ſingularly elegant, curved into an orbicular flat form, near an inch broad, naked, glaucous, purpliſh, finely reticulated, fringed with briſtly teeth. *Seeds* numerous, tranſverſely corrugated.

3. M. *circinata*. Pinnate Kidney Medick. Linn. Sp. Pl. 1096. (Falcata foliis anthyllidis; Riv. Tetrap. Irr. t. 87.)—Legume kidney-ſhaped, toothed at the edge. Leaves pinnate, lyrate, entire.—Native of Spain, Italy, and the Levant. Annual. *Leaves* ſomewhat like thoſe of *Anthyllis vulneraria*, pinnate, with obovate, entire, thick, hairy leaflets, the odd one very large. The earlieſt leaves are ſimple. *Flowers* yellow, two or three on a long bracteated axillary ſtalk, like thoſe of a *Lotus*. *Legume* ſmaller and leſs elegant than in the laſt, hairy. Willdenow and Gærtner deſcribe a variety whoſe legume is ſmaller, without teeth, which may well prove a ſpecies. We have never ſeen it.

4. M. *ſativa*. Lucern, or Purple Medick. Linn. Sp. Pl. 1096. Mart. Ruſt. t. 48. Engl. Bot. t. 1749. (Medica legitima; Cluſ. Hiſt. v. 2. 242.)—Flower-ſtalks racemoſe. Legumes contorted. Stem erect, ſmooth.—In dry paſtures and by road ſides in France and Spain, as well as occaſionally in England, but it is hardly wild with us. For its deſcription, and agricultural uſe, ſee Lucern. The *legume* is frequently ſo much convoluted, that it rather belongs to the next ſection.

5. M. *falcata*. Yellow Sickle-podded Medick. Linn. Sp. Pl. 1096. Mart. Ruſt. t. 86, 87. Engl. Bot. t. 1016.—Flower-ſtalks racemoſe. Legumes moon-ſhaped. Stem procumbent.—Found in dry gravelly places in various parts of Europe. In England chiefly about Norwich and Bury. It greatly reſembles the laſt, but does not grow erect, and the *legume* is merely ſickle-ſhaped, not contorted. The *flowers* vary from yellow to purple, and are often of a green hue, combined of both the former tints. Theſe two laſt ſpecies are perennial, and perhaps neareſt akin to the firſt, *arborea*.

6. M. *glutinoſa*. Clammy Medick. Willd. Sp. Pl. v. 3. 1406.—Flower-ſtalks racemoſe. Legumes falcate, twiſted, hairy and viſcid, like the calyx. Leaflets obovate, toothed at the ſummit.—Native of graſſy land in Tauria. Willdenow ſays it is very ſimilar to *M. falcata*, but differs in having obovate *leaflets*, and a hairy viſcid *calyx*. The *ſtems* are aſcending, and downy.

7. M. *lupulina*. Black Medick, or Noneſuch. Linn. Sp. Pl. 1097. Curt. Lond. faſc. 2. t. 57. Engl. Bot. t. 971. Mart. Ruſt. t. 19. (Trifolium luteum lupulinum; Ger. em. 1186.)—Spikes ovate. Legumes kidney-ſhaped, rugged and veiny, ſingle-ſeeded. Stem procumbent.—Frequent in the meadows and paſtures of Europe. It is annual, flowering all ſummer long, and is much cultivated, as an artificial graſs, for a crop of hay, or as fodder for ſheep. The *ſtems* ſpread widely. The *leaflets* are broad, roundiſh-obovate, finely toothed. *Flowers* yellow, ſmall, in denſe ovate ſtalked ſpikes, very much reſembling ſome of the common yellow

ſpecies

species of *Trifolium*, with which indeed the whole habit of the plant accords, but the curved, black, rugged *legumes*, as they ripen, conspicuously distinguish it.

8. M. *obscura* Doubtful Medick. Retz. Obs. fasc. 1. 25. t. 1.—Flower-stalks racemose. Legumes kidney-shaped, with two seeds. Stipulas toothed. Leaflets obovate, somewhat rhomboid. Stems recumbent.—Supposed by Retzius, who had it by accident with other seeds, to be a native of Germany. *Root* annual. The habit and flowers are like many of the next section, but the *legume* is merely orbicular, not cochleated, or truly spiral; its diameter scarcely a quarter of an inch.

** *Legumes spirally convoluted.*

9. M. *prostrata*. Slender Prostrate Medick. Linn. Suppl. 340. Jacq. Hort. Vind. v. 1. 39. t. 89. Ehrh. Pl. Select. 49. —Flower-stalks racemose. Stem procumbent, thread-shaped, much branched. Legumes thrice convoluted, thick-edged, without prickles. Stipulas bristle-shaped, undivided. Leaflets nearly linear.—Native of exposed stony ground in Hungary and Italy. It is known by its long, slender, much branched *stems*, simple *stipulas*, very narrow *leaflets* toothed merely at the point, and small orbicular *legumes*, consisting of two or three complete spiral turns, thick at the edge, destitute of teeth or prickles, and very slightly downy. The *flowers* are yellow, and, like the rest of the plant, vary much in size according to the richness of the soil. The *root* is perennial, in which it differs from most of this second section, and agrees with *sativa* and *falcata*, which also it approaches in habit; but the whole nature of the *legume* has induced us to remove it hither.

10. M. *orbicularis*. Flat Snail Medick. (M. polymorpha orbicularis; Linn. Sp. Pl. 1097. Cochleata fructu orbiculato; Riv. Tetr. Irr. t. 88. f. 1.—Moris. sect. 2. t. 15. f. 1, 2.)—Stalks one or two-flowered. Stipulas in many capillary segments. Legumes orbicular, depressed, with radiating veins, and no teeth.—Native of fields in the south of Europe. Annual. *Stems* long and prostrate, angular, slender, smooth. *Leaflets* obovate, sharply toothed, smooth. *Stipulas* deeply pinnatifid. *Flowers* very small, yellow, on slender axillary stalks. *Legumes* smooth, orbicular, depressed, above three quarters of an inch in diameter, singularly neat, marked with elevated radiating veins, and of a glaucous or purplish hue. This is one of those hardy annuals, cultivated in curious gardens, by the name of *Snails*, the *Scorpiurus vermiculata* generally accompanying them under the appellation of *Caterpillars*, which its legumes strikingly resemble.

11. M. *rugosa*. Rugged Snail Medick. Lamarck Dict. v. 3. 632. (M. elegans; Willd. Sp. Pl. v. 3. 1408. Cochleata fructu rugoso; Riv. t. 88. f. 5. Moris. sect. 2. t. 15. f. 4.)—Stalks about two-flowered. Stipulas toothed. Legumes orbicular, depressed, with radiating elevated veins, a thick edge, and no teeth.—Native of Sicily. We have seen no specimen of this, but it should seem to be only a slight variety of the last, except the *stipulas* may serve to distinguish them.

12. M. *scutellata*. Common Snail Medick. Lamarck Dict. v. 3. 633. (M. polymorpha scutellata; Linn. Sp. Pl. 1097. Cochleata fructu scutellato; Riv. t. 88. f. 2. t. 89. f. 1. Moris. sect. 2. t. 15. f. 3.)—Stalks about two-flowered. Stipulas half arrow-shaped, toothed. Legumes globular, spiral, convex beneath, the convolutions erect, rugose, without teeth.—Frequent in corn fields in the south of Europe, and the most common kind in our gardens. It differs specifically from *M. orbicularis* in having broad *stipulas*, often strongly toothed, but not divided into deep capillary segments. The *legume* moreover differs widely in being globose, in consequence of the edges of its convolutions being turned upwards, or erect, and they may be pulled asunder like a rolled slip of paper. The whole *herb* is more or less downy.

13. M. *Helix*. Small Snail Medick. Willd. Sp. Pl. v. 3. 1409. (M. lævis; Desfont. Atlant. v. 2. 213.)—Stalks many-flowered. Stipulas strongly toothed. Legumes orbicular, flat, of two spiral distant turns, concentrically veined, without spines.—We have from the south of France what answers well to Willdenow's description, nor have we the least doubt concerning the synonym of Desfontaines. The *leaflets* are obovate, rounded, with shallow teeth. *Stipulas* much like the last. *Flowers* four or five on a stalk. *Legumes* hairy, a quarter of an inch only in diameter, marked with concentric or spiral interbranching veins, in which respect it differs essentially from the three last, as well as from *M. obscura*, to which Willdenow compares it; a character which seems to have been noted by Desfontaines.

14. M. *tornata*. Screw-turned Snail Medick. Willd. Sp. Pl. v. 3. 1409. (M. polymorpha tornata; Linn. Sp. Pl. 1098. Herb. Linn. Cochleata fructu tornatili; Riv. t. 88. f. 4.)—Stalks many-flowered. Stipulas deeply toothed. Legumes cylindrical, flat at each end, of many, rather distant, horizontal, smooth, thin-edged turns, without spines. —Native of the south of Europe. The only specimen we have ever seen is that of Linnæus, who by quoting a figure of Morison which belongs to the following, has led some botanists astray. Lachenal took one for the other, and Desfontaines has confounded the two. Whether they are more than varieties may perhaps be doubted, as is the case with some others of the genus; but they appear distinct. The real *tornata*, figured by Rivinus in that curious tab. 88, which is wanting in many copies of his book, has a small *legume*, that appears to be neatly turned, exactly like a screw, the convolutions being flat and horizontal, rather distant, with a thin smooth even edge, parallel and near to which runs a principal concentric spiral rib or nerve, connected by reticulated veins with the centre, and sending off a minute branch, here and there, to the margin. The *stipulas* have generally a few deep taper-pointed teeth. The *flowers* are rather large, four or five on a stalk. *Leaves* sharply toothed.

15. M. *turbinata*. Close-turned Snail Medick. Willd. Sp. Pl. v. 3. 1409. (M. polymorpha turbinata; Linn. Sp. Pl. 1098. Cochleata fructu turbinato; Riv. t. 88. f. 3. Moris. sect. 2. t. 15. f. 5.)—Stalks many-flowered. Stipulas deeply toothed. Legumes ovate, convex at each end, of many, closely imbricated, thick-edged, even turns, without spines.—Native of Italy and the south of France. Like the last in habit and general characters, but the *legume* is twice as large, ovate, its convolutions crowded close together, as if imbricated upwards, presenting a thick edge outwards, along which runs the same spiral concentric nerve which in the *M. tornata* is situated within the margin. Willdenow, who appears to have paid great attention to these plants, has removed a synonym of J. Bauhin, cited here by Linnæus, to the following, to which it evidently belongs. Linnæus indeed confounded the two, and Lachenal, led perhaps by Bauhin's synonym, took the *tuberculata* for *turbinata*. We cannot however follow Willdenow in here quoting Bauhin's *Medica scutellata*, v. 2. 384, which appears to us the real *Medicago scutellata*, our n. 12.

16. M. *tuberculata*. Warty Snail Medick. Willd. Sp. Pl. v. 3. 1410 (M. polymorpha tuberculata; Retz. Obs. fasc. 2. 23. Medica magna turbinata; Bauh. Hist. v. 2. 385. Cochleata fructu verrucoso; Riv. t. 88. f. 6. Moris. sect. 2. t. 15. f. 6.)—Stalks about two-flowered. Stipulas deeply

deeply toothed. Legumes nearly cylindrical, flattiſh at each end, of many horizontal crowded turns, beſet with a double row of corrugated warts.—Native of the ſouth of Europe. This differs from the laſt in having only one or two *flowers* on each ſtalk, which ſeems to be conſtant, and in the rather ſmaller, more cylindrical, *legumes*, the outer edge of whoſe convolutions is cloſely beſet with a double row of bluntiſh warts, imbedded in a ſort of granulated ſkin. In an early ſtate theſe warts are rather bluntiſh ſpines.

17. M. *aculeata*. Prickly Snail Medick. Willd. Sp. Pl. v. 3. 1410. (Cochleata fructu turbinato et echinato; Riv. t. 88. f. 7?)—"Stalks about two-flowered. Stipulas toothed. Leaflets ſomewhat rhomboid. Legumes cylindrical, flattiſh at each end, of many turns, beſet with thick ſhort marginal ſpines."—Native country unknown. Willdenow deſcribes it as very like the preceding, but diſtinct, the *legumes* being beſet with unequal, thick, and very ſhort, prickles. Not having ſeen this plant, we quote with doubt the figure of Rivinus, which anſwers pretty well to the deſcription. Willdenow ſeems not to have known this tab. 88.

18. M. *Murex*. Thorny Snail Medick. Willd. Sp. Pl. v. 3. 1410. (Cochleata fructu duriùs echinato; Riv. t. 88. f. 10?)—"Stalks about two-flowered. Stipulas deeply toothed, or fringed. Leaflets obovate. Legumes cylindrical, rather convex at each end, of many turns, beſet with ſtraight thorns."—Native country unknown, but Willdenow had the plant alive, as well as the laſt. He deſcribes it with cylindrical turbinate legumes, beſet with thick awl-ſhaped thorns, and differing from the laſt in having obovate obtuſe *leaflets*, the lower ones *obcordate*; linear-awl-ſhaped *ſtipulas* with fringe-like teeth, not lanceolate ones toothed only at the baſe; and longer thorns upon the fruit. We quote Rivinus with doubt, for the ſame reaſon as before, though we have ſcarcely any heſitation about either of his figures.

19. M. *intertexta*. Entangled Prickly Medick. Willd. Sp. Pl. v. 3. 1411. (M. polymorpha intertexta; Linn. Sp. Pl. 1098. Cochleata fructu echinato maximo; Riv. t. 88. f. 9; and t. 90. Moriſ. ſect. 2. t. 15. f. 7, 8, 9.)—Stalks about two-flowered. Stipulas deeply toothed. Legumes oval, of many turns, beſet with two rows of long, awl-ſhaped, cloſe-preſſed thorns, alternately divaricated.—Native of the ſouth of Europe. Diſtinguiſhed from all the foregoing by its nearly globular *legumes*, about the ſize of a gooſeberry, compoſed of ſix or ſeven cloſe convolutions, concealed by the long ſharp thorns, which cover the whole fruit, and which being alternately depreſſed, in two oppoſite directions, appear matted together. In all our ſpecimens theſe thorns are ſmooth; Willdenow deſcribes them as pubeſcent. The *flowers* are from two to four on each ſtalk. *Stipulas* fringed with long ſharp teeth. *Leaflets* obovate, or ſomewhat rhomboid, narrow, ſharply toothed. This ſpecies is often met with in gardens.

20. M. *ciliaris*. Hairy Prickly Medick. Willd. Sp. Pl. 1411. (M. polymorpha ciliaris; Linn. Sp. Pl. 1099. Cochleata fructu echinato rotundo; Riv. t. 88. f. 8.)—Stalks about two flowered. Stipulas deeply toothed. Legumes oval, of many turns, beſet with two rows of ſhort awl-ſhaped hairy thorns, ſpreading in two directions.—"Native of the ſouth of France." *Willdenow*. Sent from Sicily by Mr. Bivona Bernardi. In habit and ſize it altogether agrees with the laſt; but the *legumes* are covered with much ſhorter hairy thorns, ranged in two rows along the edge of their convolutions, ſpreading in oppoſite directions, but not depreſſed.

21. M. *carſtienſis*. Creeping-rooted Medick. Jacq. Coll. v. 1. 86. Ic. Rar. t. 156. Curt. Mag. t. 909.—Stalks many-flowered. Leaflets ovate. Stem erect. Root creeping. Legumes depreſſed, of many turns, fringed with two rows of ſtraight ſpreading briſtles.—Native of the alps of Carinthia and Carniola, ſaid to have been introduced into our gardens in 1790. It is remarkable for its perennial creeping *root*, and upright, ſquare, almoſt ſhrubby *ſtem*. The *leaflets* moreover are ovate, not obovate. *Flowers* ſix or eight on each ſtalk, of a bright yellow, their ſtandard ſtreaked with red. *Legumes* black, not half the ſize of the two preceding, of fewer turns, and depreſſed, the edges fringed with two divaricated rows of long briſtles.

22. M. *maculata*. Spotted Medick. Sibth. Oxon. 232. Willd. Sp. Pl. v. 3. 1412. (M. polymorpha arabica; Linn. Sp. Pl. 1098. Fl. Brit. 797. Engl. Bot. t. 1616. Curt. Lond. faſc. 3. t. 47. Mart. Ruſt. t. 76. Cochleata fructu longiùs echinato; Riv. t. 88. f. 12. Moriſ. ſect. 2. t. 15. f. 12?)—Stalks two or three-flowered. Leaflets inverſely heart-ſhaped, ſpotted. Stipulas dilated, ſharply toothed. Legumes depreſſed, their convolutions fringed with numerous, long, ſpreading briſtles.—Native of the more temperate countries of Europe. Found in the ſouth of England, on a gravelly ſoil, flowering in May and June. The *ſtems* are proſtrate. *Root* annual. *Leaflets* diſtinguiſhed by their obcordate ſhape, and a black or purpliſh ſpot in the middle of their diſk, which however diſappears from the later or upper leaves. *Stipulas* half-heart-ſhaped, with ſharp broad teeth. *Flowers* two or three on a ſtalk, yellow, as indeed are all of this ſection of the genus. *Legumes* ſmall, depreſſed, of ſeveral turns, marked with concentric nearly parallel ribs, and fringed with long, ſpreading, ſlender, and rather weak ſpines, or briſtles, the whole pale brown or whitiſh when ripe.—The three varieties enumerated in the Flora Britannica are now eſteemed diſtinct ſpecies, at leaſt the β and γ. The δ we know only by the report of Dillenius.

23. M. *truncatula*. Abrupt Medick. Gærtn. v. 2. 350. t. 155. Moriſ. ſect. 2. t. 15. f. 17. (M. tentaculata, by miſtake; Willd. Sp. Pl. v. 3. 1413.)—Stalks about two-flowered. Stipulas toothed. Legumes cylindrical, ſpiral, flat at each end, beſet with two ranks of ſmooth, lanceolate, cloſe-preſſed prickles.—Native of the ſouth of Europe. Willdenow had it living, and deſcribes the *leaflets* as obovate; *ſtipulas* awl-ſhaped and toothed; *ſtalks* two-flowered; *legumes* as above. We ſhould think it a variety of the following, but not having ſeen it, we dare not decide.

24. M. *coronata*. Coronet Medick. Lamarck Dict. v. 3. 634. Willd. Sp. Pl. v. 3. 1413. (M. polymorpha coronata; Linn. Sp. Pl. 1098. Moriſ. ſect. 2. t. 15. f. 16. Medica coronata cherleri parva; Bauh. Hiſt. v. 2. 386.)—Stalks many-flowered. Leaflets inverſely heart-ſhaped. Legumes cylindrical, hairy, flat at each end, of about two turns, bordered with an aſcending and deſcending row of ſtrong, cloſe-preſſed, awl-ſhaped ſpines.—Native of the ſouth of France. We have it from Gerard. This is a very ſmall ſpecies, about three or four inches high, hardly branched; with lanceolate ribbed *ſtipulas*, ſcarcely toothed except at the baſe; ſeveral ſmall *flowers* on each ſtalk; and curious little *legumes*, well repreſented in the figures quoted. The *leaflets* are hairy, obcordate, ſtrongly toothed.

25. M. *apiculata*. Wheel-toothed Medick. Willd. Sp. Pl. v. 3. 1414. (M. coronata; Gærtn. v. 2. 349. t. 155. Moriſ. ſect. 2. t. 15. f. 14?)—Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes depreſſed, of three turns, ſtrongly reticulated, with two rows of minute, diverging, marginal teeth.—Native of the ſouth

south of Europe. We have it from Professor Lachenal under the name of *M. coronata*, but it is very distinct from the last, being a much larger plant, with deeply fringed *stipulas*, obovate smooth *leaflets*, and flattened strongly reticulated *legumes*, whose teeth are scarcely more prominent than their veins.

26. M. *denticulata*. Sickle-toothed Medick. Willd. Sp. Pl. v. 3. 1414.—" Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes depressed, of two turns, reticulated, with two rows of diverging marginal spines."—Native of the south of Europe. Very near the last, differing only in its longer bristle-like marginal spines. *Willd.* We have from the sea-coast near Cley, in Norfolk, what seems to answer to these characters, except that in ours the *leaflets* are inversely heart-shaped. We know not whether this has been noticed as a British plant, or whether it be the *M. polymorpha* δ of Fl. Brit. adopted there from Dillenius.

27. M. *muricata*. Flat-toothed Medick. Willd. Sp. Pl. v. 3. 1414. (M. polymorpha muricata; Linn. Sp. Pl. 1098. Fl. Brit. 798 γ. Moris. sect. 2. t. 15. f. 11. Trifolium cochleatum, modiolis spinosis; Pluk. Phyt. t. 113. f. 6.)—Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate, somewhat rhomboid. Legumes depressed, of five turns, with short, depressed, radiating teeth.—Native of dry ground in France and Italy. Said by Ray to have been found on the sea bank at Orford, Suffolk. The structure of its *legume* is abundantly different from the foregoing five species, the teeth being horizontal, and in single rows, nor is the surface veiny or reticulated. The *leaflets* are hairy. *Flowers* from two to four on each stalk.

28. M. *Gerardi*. Gerardian Medick. Willd. Sp. Pl. v. 3. 1415. Waldst. and Kitaib. Hungar. Moris. sect. 2. t. 15. f. 18.—" Stalks about two-flowered. Stipulas with setaceous teeth. Leaflets obovate. Legumes hairy, depressed, of five turns, with awl-shaped, projecting, hooked spines."—Native of Spain, Narbonne, and Hungary.—We know it only from Willdenow, who had dried specimens before him.

29. M. *recta*. Upright Dwarf Medick. Willd. Sp. Pl. v. 3. 1415. (M. polymorpha recta; Desfont. Atlant. v. 2. 212.)—Stalks single-flowered. Stipulas entire. Leaflets wedge-shaped, downy. Stem erect. Legumes spiral, with hooked teeth.—Native of Barbary. About four inches high, annual, downy and silky. *Leaflets* small, with minute teeth. *Stipulas* ovate, acute. *Flowers* axillary, on very short stalks. *Legume* orbicular.

30. M. *marina*. Downy Sea Medick. Linn. Sp. Pl. 1097. Willd. Sp. Pl. v. 3. 1415. Cavan. Ic. v. 2. 26. t. 130. (Cochleata incana; Riv. t. 91. f. 2. t. 88. f. 15.)—Stalks many-flowered. Herb procumbent, very downy. Leaflets obovate, crenate or entire. Stipulas undivided. Legumes very hairy, with strong radiating teeth.—Native of the sandy sea-coast in the north of Africa, and south of Europe. *Root* perennial. *Stems* prostrate, much branched, densely clothed with soft hoary hairs, as is every part of the herbage. The *leaflets* are wedge-shaped, broad, but scarcely obovate, either quite entire, or slightly crenate at the end only. *Flowers* numerous, of a full yellow, in dense round heads. *Legumes* with several convolutions, edged with prominent, awl-shaped, strong hairy teeth.—This can be confounded with no other, and even Linnæus keeps it separate from the varieties of his supposed species *polymorpha*.

31. M. *Terebellum*. Prickly Screw Medick. Willd. Sp. Pl. v. 3. 1416. (M. aculeata; Gærtn. v. 2. 349. t. 155. Moris. sect. 2. t. 15. f. 20, 21. Cochleata fructu rarius echinato; Riv. t. 88. f. 11?) Stalks with several flowers. Stipulas deeply toothed. Leaflets obovate, obtuse. Legumes cylindrical, flat at each end, of five turns, with two rows of diverging, very short, awl-shaped spines.—Native of the south of Europe. In habit this is among the more luxuriant procumbent species. The *leaflets* are broad, strongly toothed; the lower ones most abrupt. Spines of the *legumes*, thick at the base, often conical, reflexed in opposite directions. The ripe *legume* is the size of a large pea. Hence we rather cite Rivinus's fig. 7 for our 17th species, *M. aculeata*, than, with Gærtner, for the present, that figure being nearly thrice as large.

32. M. *tribuloides*. Caltrop Medick. Lamarck Dict. v. 3. 635. Willd. Sp. Pl. v. 3. 1416.—" Stalks two-flowered. Stipulas toothed. Leaflets obovate. Legumes cylindrical, flat at each end, of five turns, with two rows of diverging conical spines."—Native of the south of Europe. Willdenow says the *legumes* are very like those of his *tentaculata*, our *truncatula*, n. 23, but larger, with longer spines, which are merely reflexed, not close-pressed. We have seen no specimen that answers to this. Willdenow had it alive.

33. M. *uncinata*. Larger Bur Medick. Willd. Sp. Pl. v. 3. 1417.—Stalks many-flowered. Stipulas toothed. Leaflets obovate. Legumes cylindrical, short, flat at each end, of several distant turns, with two spreading rows of long, awl-shaped, hooked spines.—Willdenow, who had this also alive, supposes it a native of the south of Europe. We find what answers very correctly to his description in the Linnæan herbarium, marked *coronata*, which is most assuredly an error. Linnæus having referred all this tribe to one species, was not sufficiently attentive to their differences, even as varieties. The *legumes* of the present are nearly globose, loosely spiral, and distinguished by their hooked prickles from nearly all the foregoing, in which mark they agree with two hereafter described, *minima* and *nigra*.

34. M. *rigidula*. Bristly Medick. Willd. Sp. Pl. v. 3. 1417. (M. polymorpha rigidula; Linn. Sp. Pl. 1098. Medica fructu cochleato spinoso; Ger. em. 1199. Cochleata fructu echinato rotundo minore; Riv. t. 88. f. 13?) Stalks with several flowers. Stipulas toothed. Leaflets obovate. Legumes cylindrical, of many turns, with conical straight spreading spines.—Native of fields in France, Italy, and Barbary.—This differs from the last in having the convolutions of the *legume* closer, the spines straight, all horizontally spreading; the *flowers* twice as large. It is difficult to adjust the synonyms of all these species. The figure of Gerard, which is also found in Lobel's Icones, v. 2. 37. f. 1, may have been done for either, but it best agrees with this. We are much in doubt concerning Rivinus's f. 13; but we cannot refer his f. 12 to the present species, because that figure so admirably and precisely represents the concentric veins of *M. maculata*, n. 22, which being a common plant, could hardly have been unknown to Rivinus.

35. M. *minima*. Little Bur Medick. Willd. Sp. Pl. v. 3. 1418. (*M.* polymorpha minima; Linn. Sp. Pl. 1099. Fl. Brit. 798 β. Fl. Dan. t. 211. Medica echinata minima; Bauh. Hist. v. 2. 386. Cochleata fructu echinato minimo; Riv. t. 88. f. 14.)—Stalks many-flowered. Stipulas half-ovate, undivided. Leaflets obovate, hairy. Legumes orbicular, hairy, of three or four turns, with two divaricated rows of hooked spines.—Native of Germany, Hungary, Switzerland, France, and England, chiefly on a calcareous soil. Mr. Woodward found it at Narburgh, Norfolk. A small prostrate downy species; its *leaflets* strongly toothed at the very summit only. *Flowers* four or five on each stalk, with a hairy calyx. *Legumes* small, orbicular,

cular,

cular, diftinguifhed by their numerous rigid, fpreading, but ftrongly hooked, prickles.

β. M. polymorpha hirfuta. Linn. Sp. Pl. 1099. (Medica echinata hirfuta; Bauh. Hift. v. 2. 386.) This is faid by Willdenow to be a variety, four times as large as the common *minima*, and lefs hairy. We know it not, but we have from Switzerland, intermixed with the common fort, a few fpecimens diftinguifhed by the long fpines of their fruit, hooked at the tip only. Thefe require inveftigation in a living ftate. They may be Bauhin's plant.

36. M. *nigra*. Black Prickly Medick. Willd. Sp. Pl. v. 3. 1418. (M. polymorpha nigra; Linn. Syft. Veg. ed. 14. 694. M. hifpida; Gærtn. v. 2. 349. t. 155. Morif. fect. 2. t. 15. f. 19.)—Stalks about two-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes cylindrical, rather depreffed, of feveral clofe turns, with long, fpreading, black, hook-tipped fpines.—Native of the fouth of France. We have no fpecimen. It feems to be diftinguifhed by the long black prickles of the fruit, whofe points are faid to be hooked, though no fuch character is fhewn in the figures quoted. Gærtner furely mifapplies Rivinus's f. 12, in which, as we have obferved under n. 34, the veins are concentric, not reticulated as Gærtner reprefents them in his *hifpida*.

37. M. *laciniata*. Jagged-leaved Medick. Willd. Sp. Pl. v. 3. 1419. (M. polymorpha laciniata; Linn. Sp. Pl. 1099. Cochleata fyriaca; Riv. Tetr. Irr. t. 91. f. 1.)—Stalks about two-flowered. Stipulas fringed with capillary teeth. Leaflets linear-wedge-fhaped, abrupt, cut. Legumes cylindrical, of many turns, with two rows of alternately divaricated, ftrong, hook-tipped fpines.—Native of the fouth of Europe and north of Africa. This fpecies is readily known by its narrow jagged *leaflets*. The *ftipulas* are cut into deep capillary fegments. *Flowers* one or two, on long flender ftalks. *Legumes* cylindrical, fomewhat elliptical, the fize of a large pea, compofed of about five clofe turns, armed with a double divaricated row of peculiarly ftrong, awl-fhaped, fmooth, polifhed fpines, very minutely hooked at their tips only.

It is proper to obferve that all the fpecies of this fecond fection have yellow *flowers* on axillary ftalks; the *ftem*, where not defcribed otherwife, proftrate, branched from the *root*, which is generally annual. The *leaflets* are always more or lefs toothed. In quoting Morifon throughout this article, we have not thought it worth while to copy his long names or definitions, but merely to cite his figures. Many of thefe remain ftill unappropriated, for want of better defcriptions. S.

Medicago, in *Gardening*, furnifhes plants of the fhrubby evergreen and herbaceous annual kinds, of which the fpecies moftly cultivated are, the tree medick, or moon trefoil (M. arborea); and the variable medick, or fnail and hedge-hog trefoil (M. polymorpha.)

The fecond fort has numerous varieties and fubvarieties, but the principal ones are, the common fnail medicago, with large fmooth pods, fhaped and twifted like a fnail; the hedge-hog medicago, with large prickly fnail-fhaped pods, armed with fpines pointing every way, like a hedge-hog; with turbinated pods; with globular pods; with orbicular pods; with long crooked pods; with double pods; with twifted pods; and with jagged leaves.

Method of Culture.—The firft fort may be raifed from feeds or cuttings.

In the former mode the feeds fhould be fown in the early fpring, on a warm border, or in pots of light mould, and plunged in a moderate hot-bed, till the plants have attained a little growth; when they fhould be gradually hardened to the full air. And in both methods the plants fhould be kept clean, and have protection in the following winter from froft, and in the fpring they fhould be planted out, fome into pots to have the management of green-houfe plants, and others into borders and nurfery rows, in dry warm fituations, the former to remain, and the latter to be occafionally tranfplanted.

But when they are increafed by cuttings, thefe fhould be planted on a bed of light rich earth, or in pots of the fame fort of mould, and plunged in a moderate hot-bed, due fhade and water being given; and when they have formed good roots, in the autumn they may be removed into other pots, or the fituations in which they are to remain, fhading and watering them till they are well rooted, when they fhould be trained up to fticks, to have ftraight ftems and regular heads, their irregular fhoots being annually pruned to keep them in order. Thefe plants are found to grow ftronger and flower better when kept in warm fituations in the open air, than when managed as green-houfe plants. They fhould, however, be fheltered in very fevere winters.

And the fecond fort and varieties may alfo be raifed from feed, which fhould be fown in the early fpring months in the places where the plants are to remain, in patches of feveral feeds, after thinning the plants to two or three of the beft, when they require no further culture. It is the double forts that are chiefly cultivated in the garden.

They both afford variety in the borders and other parts, and the former in the green-houfe among other fimilar plants.

MEDICAL Electricity. It is natural to imagine, that a power of fuch efficacy as that of electricity, would be applied to medical purpofes; efpecially fince it has been found invariably to increafe the infenfible perfpiration, to quicken the circulation of the blood, and to promote the glandular fecretion. Accordingly, many inftances occur in the later period of the hiftory of this fcience, in which it has been tried, on various occafions, with confiderable advantage and fuccefs. Among the variety of cafes to which it has been applied, there are none in which it feems to have been prejudicial, except thofe of pregnancy and the venereal difeafe. In moft diforders, in which it has been ufed with perfeverance, it has given, at leaft, a temporary and partial relief, and in many effected a total cure. The firft inftance that occurs of its falutary effect, was that of a woman, who was cured in a quarter of an hour of a contracted finger, by M. Kratzenftein, at Halle, fo early as the year 1744. It was afterwards applied in a variety of paralytic cafes, by M. Jallabert of Geneva, in 1747; M. Sauvages of the academy in Montpellier, in the courfe of whofe experiments it appeared, that electrification increafes the circulation of the blood about one-fixth; Mr. Patrick Brydone in Scotland, in 1757; the abbé Nollet and others: in feveral of the cafes concerned prefent relief was obtained; but the beneficial effect does not appear to have been permanent. One inftance occurs, related by Dr. Hart of Shrewfbury, and recorded in the Phil. Tranf. vol. xlviii. part ii. p. 785, in which electrification was injurious, and brought on univerfal palfy on a young perfon, whofe right arm was paralytic; and though this palfy was removed by a courfe of medicine, the difeafed arm remained incurable. It alfo appears from a number of experiments made by Dr. Franklin in paralytic cafes, that no permanent advantage was derived from electricity in this diforder; and Mr. Wefley, who was long engaged in a courfe of medical electricity for the benefit of perfons in his connection, obferves, that though many paralytics have been helped by it, no palfy of a year's ftanding has been thoroughly cured by it. However, a remarkable inftance more lately occurs, in which an hemiplegia was cured by this

this means, under the direction of a physician at Greenwich. The patient was in such a state, that boiling water might be applied from her hand to her shoulder, and from her shoulder to her foot, on the diseased side, without being felt. This person was electrified, by drawing sparks from the palsied side, and giving shocks, beginning with stronger shocks, till she began to feel them, and continuing moderate ones, for 18 days; and in that time, during 31½ hours, the number of shocks was 141; and this perseverance was attended with such success, that her feeling was quite restored, and that she became capable of walking, and of writing with the hand, the use of which she had lost. Dr. de Haen observes, that with respect to partial palsies, electrification never did the least harm; and that one or two persons, who had received no benefit from it in six entire months, were yet much relieved by persevering in the use of it; and that some persons discontinuing it, after having received some benefit from it, relapsed again; but afterwards, by recurring to the use of electricity, recovered, though more slowly than before.

Dr. Hart, in 1756, mentions a cure performed on a woman, whose hand and wrist had been for some time rendered useless, by a violent contraction of the muscles; but the most remarkable case of this kind is that related by Dr. Watson, Phil. Transf. vol. liii. p. 10.

The patient, about seven years of age, was seized with an universal rigidity of her muscles, so that her whole body felt more like that of a dead corpse than of a living person; Dr. Watson electrified her, at convenient intervals, from the middle of November 1762, to the end of January 1763, when every muscle of the body was perfectly flexible, and subservient to her will, so that she could stand, walk, and run like other children of her age. Mr. Miles Partington also communicated to the Royal Society a surprising instance of the cure of a very great degree of contraction and rigidity in the sterno-mastoideus muscle by means of electrical sparks and shocks. (Phil. Transf. vol. lxviii. part i. p. 97, &c.) Mr. Wilson mentions a single instance, in which he had cured deafness of seventeen years continuance; but he acknowledges that he tried similar experiments on six other deaf persons without success.

Mr. Lovet and Mr. Wesley have extended the medical application of electricity to a greater variety of cases than any others. Mr. Lovet observes, in his "Essay," that electricity is almost a specific in all cases of violent pains, of however long continuance, in any part of the body; as in obstinate head-aches, the tooth-ache, the sciatica, the cramp, and disorders resembling the gout; and that it has seldom failed to cure rigidities, or a wasting of the muscles, and hysterical disorders; he adds, that it cures inflammations, and a fistula lachrymalis; that it has stopped a mortification, and dispersed extravasated blood; that it has been of excellent use in bringing to a suppuration, or in dispersing without suppuration, obstinate swellings of various kinds, even those that were scrophulous; that it has cured the falling-sickness, and several kinds of fits, and a disorder that seems to have been a gutta serena. He advises to begin, in general, with simple electrification, especially in hysterical cases; then to proceed to take sparks, and lastly, to give moderate shocks. Mr. Wesley observes, that he has scarcely known an instance, in which shocks all over the body have failed to cure a tertian or quartan ague; he mentions cases of blindness cured and relieved by it, and hearing given by it to a person who was born deaf; and he further says, that it has cured bruises, running sores, the dropsy, and a palsy in the tongue; and that it has brought away gravel from the kidnies. In hysterical cases, he recommends the patient's being simply electrified, by sitting on cakes of resin, at least for half an hour morning and evening; and then taking small sparks, and afterwards giving shocks, more or less strong as the disorder requires. Dr. Antonius de Haen, in his "Ratio Medendi," cited by Dr. Priestley (Hist. Elect. vol. i. p. 485, 8vo.), informs us, that a paralysis and trembling of the limbs, from whatever cause it arose, never failed to be relieved by electricity; and that it also certainly cures St. Vitus's dance; that it has been of some use in cases of deafness; but failed in its application to a gutta serena, and strumous neck. Mr. Hey, surgeon of Leeds, mentions several cases in which the power of electricity has been successfully applied to an "amaurosis." The machine was used twice a day; the patient was placed on a stool with glass legs, and had sparks drawn from the eyes and parts surrounding the orbit, especially where the superciliary and infra-orbitary branches of the fifth pair of nerves spread themselves. After this operation had been continued for half an hour, the patient was made to receive for an equal time slight shocks through the affected parts, which were sometimes directed across the head, from one of the temples to the other, but chiefly from the superciliary and infra-orbitary foramina to the occiput. Med. Obs. & Enq. vol. v. p. 1, &c.

In rheumatic cases, Mr. Ferguson observes, that he has generally found electricity successful, by continuing to take sparks from the places where the pain lies, till the skin has been red and pimpled, and the patient has felt a glowing warmth where the sparks were drawn off; and the same method has also proved effectual in old sprains. The use of electricity has also been recommended in cases of sudden death. See Drowning.

In all cases where shocks are given, gentle ones should be first used: and if the disorder continues, they may be gradually increased; and they should be confined to the affected part. The efficacy of electricity in the tooth-ache is so great, that it seldom or ever fails to give immediate relief, unless the tooth be very much decayed. The following instrument will serve for this purpose: it consists of two wires, A B and B E, fixed in the piece of bored wood H, and bent at C D and F G, and at A and B, as in *fig.* 1, *Plate* XV., *Electricity*. If the affected tooth be brought within the two wires at E, and the ring A or B be connected by a chain with the outside of a charged jar, and the other ring be connected by a chain with the knob of the jar, the shock will pass through the wires, and consequently through the tooth. The modes of applying electricity to the human frame, formerly used, were by the shock and spark, and sometimes, though rarely, by single electrification. These modes are now varied and multiplied according to the circumstances of the patient, and the nature of his disorder. Under the conduct of Mr. Birch, an eminent surgeon, who particularly directed his attention to the improvement and application of medical electricity, and of other gentlemen of the profession who have pursued the same course, the cases in which electricity may be employed with success have been ascertained, and its advantages evinced. For an account of this medical apparatus, and of various modes of applying it in different disorders, see Adams's Essay on Electricity, chap. 15, 8vo. 1785.

Dr. Cullen says, that electricity, when properly applied, is one of the most powerful stimulants that can be used to act upon the nervous system of animals. Mr. Birch considers electricity, applied under the form of a fluid, as a sedative, under that of a spark or friction, as a stimulant, and by way of a shock, as a deobstruent, in its action.

Under this head of medical electricity it may not be improper to mention those medicated tubes, the imaginary virtues of of which were first discovered by Signior Pivati, at Venice, and which were much recommended in the years 1747 and 1748, both in Italy, and by Mr. Winkler at Leipsic. These gentlemen imagined, that odorous substances, confined in excited glass vessels, would transpire through the pores of the glass, and communicate their medicinal virtue to the atmosphere of a conductor, and to all persons in contact with it; and that these substances would yield their virtues by being held in the hands of persons electrified; and they pretended that many cures were wrought in this way by the operation of medicines, without being taken into the stomach; but the whole was soon discovered to be a fallacy; and it was incontestibly proved, that no effluvia could pass from the included substances through the pores of excited glass; and that no method was known for causing the power of medicine to insinuate itself into the human body by electricity. Dr. Franklin, by proving that glass was impermeable to the electric fluid itself, and that its electricity was collected from the rubber, &c. evinced the absurdity of every attempt to transmit the effluvia of any substance through the glass. See Franklin's Letters, p. 82, &c.

MEDICI, Cosmo de, in *Biography*, a citizen of Florence, born in that city in 1389, was the eldest son of John, or Giovanni de Medici, who laid the foundation of that greatness which his posterity enjoyed for several ages. By a strict attention to commerce, John acquired immense wealth; by his affability, moderation, and liberality he ensured the confidence and esteem of his fellow-citizens. Without seeking after the offices of the republic, he was honoured with them all. "The maxims," says Mr. Roscoe, "which, uniformly pursued, raised the house of Medici to the splendour which it afterwards enjoyed, are to be found in the charge given by this venerable old man on his death-bed to his two sons." These, on account of their excellence, of the authority by which they were enforced, and of the successful application of them by his posterity, we shall transcribe. "I feel," said he, "that I have lived the time prescribed me. I die content; leaving you, my sons, in affluence and in health, and in such a station, that while you follow my example, you may live in your native place honoured and respected. Nothing affords me more pleasure than the reflection that my conduct has not given offence to any one; but that, on the contrary, I have endeavoured to serve all persons to the best of my abilities. I advise you to do the same. With respect to the honours of the state, if you would live with security, accept only such as are bestowed on you by the laws, and the favour of your fellow-citizens; for it is the exercise of that power which is obtained by violence, and not of that which is voluntarily conferred, that occasions hatred and violence." At the death of this venerable man, in 1428, Cosmo had already attained to high respectability as well in the political as in the commercial world. He had engaged deeply, not only in the extensive commerce by which the family had acquired its wealth, but in the still weightier concerns of government. In the year 1414, when Balthasar Cossa, who had been elected pope, and had assumed the title of John XXIII., was summoned to attend the council of Constance, he chose to be accompanied by Cosmo de Medici, among other men of eminence, whose high characters might countenance his cause. On the death of his father, Cosmo succeeded to the influence possessed by him as head of that powerful family, which rendered him the first citizen of the state, though without any superiority of rank or title. He supported and augmented the family dignity. His conduct was uniformly marked by urbanity and kindness to the superior ranks of his fellow-citizens, and by a constant attention to the interests and wants of the lower class of citizens, whom he relieved with unbounded generosity. By these means he acquired numerous and zealous partizans, whom he considered rather as pledges for the continuance of the power which he possessed, than as instruments to be employed in the ruin and subjugation of the state.

The authority which Cosmo and his descendants exercised in Florence during the 15th century consisted rather in a tacit influence on their part, and a voluntary acquiescence on that of the people, than in any prescribed or definite compact between them. The form of government was that of a republic, directed by a council of ten officers, and a chief executive officer, called the *Gonfaloniere*, or standard bearer, who was chosen every two months. Under this establishment, the citizens imagined they were possessed of the full exercise of their liberties; but such was the influence of the Medici, that they generally assumed to themselves the first offices of the state, or nominated such persons as they esteemed fit for those employments. In this, however, they always paid great respect to popular opinion. Notwithstanding the great prudence and moderation of Cosmo's public conduct, the discontent of the Florentines, with the bad success of the war against Lucca, gave occasion to the preponderance of a party led on by Rinaldo de' Albizi, which, in 1433, after filling the magistracies with their own creatures, seized the person of Cosmo, and proceeded judicially against him, on the pretence that his influence was hazardous to the state. He was committed to prison, in which he remained for several days, in constant apprehension of some violence being offered to his person; but he still more dreaded that the malice of his enemies might make attempts upon his life by poison. On the news of his danger, several princes and states of Italy interfered in his behalf; and in conclusion, he was banished to Padua for ten years, and several other members and friends of the Medici family underwent a similar punishment. He was received with marked respect by the Venetian government, and took up his abode in the city of Venice. Within a year of his retreat, Rinaldo was himself obliged to quit Florence, and Cosmo being recalled, he returned amidst the acclamations of his fellow-subjects. Some victims were offered to his future security, and the gonfaloniere who had pronounced his sentence, with a few others of that party, were put to death. Measures were now taken to restrict the choice of magistrates to the partizans of the Medici, and alliances were formed with the neighbouring powers for the avowed purpose of supporting and perpetuating the system by which Florence was from that time to be governed. The manner in which Cosmo employed his authority, has conferred upon his memory the greatest honour. From this time his life was an almost uninterrupted series of prosperity. The tranquillity enjoyed by the republic, and the satisfaction and peace of mind which he experienced in the esteem and confidence of his fellow citizens, enabled him to indulge his natural propensity to the promotion of science, and the patronage and encouragement of learned men. The richest private citizen in Europe, he surpassed almost all sovereign princes in the munificence with which he patronized literature and the fine arts. He assembled around him some of the most learned men of the age, who had begun to cultivate the Grecian language and philosophy. He established, at Florence, an academy expressly for the elucidation of the Platonic philosophy, at the head of which he placed the celebrated Marsilio Ficino. He collected from all parts, by means of foreign correspondences, manuscripts of the

Greek,

Greek, Latin, and Oriental languages, which were the foundation of the Laurentian library. He gave great encouragement to the arts of painting, sculpture, and architecture, by the vast sums which he expended in the public edifices of the city, as well as in his private palaces. He also collected the valuable remains of ancient art in statues, vases, gems, and medals; and all his treasures were made liberally accessible to the curious.

Towards the latter period of his life, a great part of the time that Cosmo could withdraw from the administration of public affairs was passed at his seats at Careggi and Caffaggiolo, where he applied himself to the cultivation of his farms; but his happiest hours were devoted to the study of letters and philosophy, or passed in the company and conversation of learned men. In his country retreats he was usually accompanied by Ficino, where, after having been his protector, he became his pupil in the study of the Platonic philosophy. His attachment to the sentiments of antiquity did not render him indifferent to the religion of his country, and he displayed his piety according to the fashion of the age, by numerous religious foundations which he munificently endowed. He even erected a noble hospital at Jerusalem for the relief of distressed pilgrims. The spirit of his government was mildness and moderation. He never assumed a state beyond that of a citizen in a republic, and avoided every open exertion of authority which could lead the Florentines to suspect they had lost their liberties.

The wealth and influence that Cosmo had acquired, had long entitled him to rank with the most powerful princes of Italy, with whom he might have formed connections, by the intermarriage of his children; but being apprehensive that such measures would give rise to suspicions that he entertained designs inimical to the freedom of the state, he rather chose to increase his interest among the citizens of Florence, by the marriage of his children into the most distinguished families of that place. Piero, his eldest son, married Lucretia Tornabuoni, by whom he had two sons, Lorenzo, the subject of the following article, and Giuliano. Cosmo conversed freely with all orders of men, and there was scarcely a citizen whom he had not some time obliged by loans of money of which he never expected the repayment. His immense wealth was not the object of envy, because he chiefly expended it upon the public; so that it was a kind of common fund in which all had an interest. Parties were again formed in Florence hostile to the predominance of the Medici. The popularity of Cosmo, however, was not to be shaken, and while he withdrew from public business, he retained the influence of his benefits and virtues. He had lost his second son, Giovanni, on whom he had placed his chief expectations, as his eldest, Piero, laboured under various bodily infirmities, and he apprehended that at his own decease the splendour of his family would close. These reflections embittered the repose of his latter days: and he exclaimed, a short time before his death, as his attendants were carrying him through the apartments of his palace, "This is too large a house for so small a family." His latter days were, however, cheered by the honourable testimony to his merit, afforded by his fellow-citizens, in a public decree, conferring upon him the noble title of *Father of his Country*, which was inscribed on his tomb, and has ever since adhered to his name.

About three weeks before his death, when his strength began rapidly to decline, he entered into conversation with Ficino, lamenting the miseries of life, and the imperfections inseparable from human nature. As he continued his discourse, his sentiments and his views became more elevated, and from bewailing the lot of humanity, he began to exult in the prospect of that happier state towards which he felt himself approaching. He died August 1st, 1464, at the age of seventy-five years, deeply lamented by a vast majority of the citizens of Florence, whom he had firmly attached to his interest, and who feared for the safety of the city from the dissentions that were likely to ensue. Roscoe's Life of Lorenzo. Univer. Hist.

MEDICI, LORENZO DE, surnamed *The Magnificent*, grandson of Cosmo, and son of Piero de Medici, by Lucretia Tornabuoni, was born on January 1, 1448. He was about sixteen years of age when Cosmo died, and had, at that time, given striking indications of extraordinary talents. From his earliest years he had exhibited proofs of a retentive and vigorous mind, which had been cultivated by a very careful education, chiefly under the direction and good conduct of his mother Lucretia, who was one of the most accomplished women of the age, and who had distinguished herself not only as a patroness of learning, but by her own writings. The disposition of Lorenzo, which afterwards gave him a peculiar claim to the title of "Magnificent," was apparent in his childhood. Having received, as a present, a horse from Sicily, he sent the donor, in return, a gift of much greater value, and on being reproved for his profuseness, he remarked, that there was nothing more glorious than to overcome others in acts of generosity. In his youth he had the advantage of the instructions of some of the wisest and most learned men of the age, in the languages, and philosophy of antiquity, and the principles of polite literature. To the latter he displayed a decided inclination by some early poetical compositions in his native tongue; but he seemed formed for excelling in every thing that becomes an object of attention. He was not less addicted to active sports and laborious exercises, than to the studies of the closet, and was equally dextrous in the management of business, and in the pursuits of arts and science. Tall in his stature, robust in his form, Lorenzo had in his person more the appearance of strength than of elegance. From his birth he laboured under peculiar disadvantages; his sight was weak, his voice harsh and unpleasing, and he was totally deprived of the sense of smell. With all these defects, his countenance was dignified, and strongly indicated the magnanimity of his character; and the effects of his eloquence were conspicuous on many important occasions. At the death of Cosmo, on account of his father's infirmities, it was thought proper immediately to initiate Lorenzo into political life. He was, accordingly, sent to visit the principal courts of Italy for the purpose of forming a personal connection with the rulers, and making observations on the circumstances of each state. He strengthened the interests of his family in an interview with Ferdinand, king of Naples, who was impressed with a high idea of his early wisdom; and the prudence and vigour of his conduct at home were materially instrumental in restoring the superiority of the Medici. In 1469, Lorenzo married Clarice, the daughter of a member of the noble family of Orsini, and in the same year Piero de Medici died, leaving his two sons, Lorenzo and Giuliano, the heirs of his power and property. Immediately after the death of his father, Lorenzo, at the request of the people of Florence, took upon himself that post of head of the republic which Cosmo and Piero had occupied. Upon the accession of Sixtus IV. to the papacy, Lorenzo, with other eminent citizens, were deputed to congratulate him on the part of the Florentine republic. On this occasion he was invested with the office of treasurer of the holy see, and he took the opportunity of his abode at Rome to make valuable additions to the remains of ancient art already collected by his family. One of of the first public occurrences after he conducted the helm of government was a revolt of the inhabitants of Volterra, on account of a dispute with the Florentine republic; by the recommendation of Lorenzo, means of force were adopted, which ended in the sack of the unfortunate city, an event that gave him much concern. In 1472, he was the means of re-establishing the academy of Pisa, and he took up his residence for a considerable time in that city for the purpose of completing the work; exerted himself in selecting the most eminent professors, and contributed to it a large sum from his private fortune, in addition to that granted by the state of Florence. Zealously attached to the Platonic philosophy, he took an active part in the establishment of an academy for its promotion, and instituted an annual festival in honour of the memory of Plato, which was conducted with singular literary splendour. While he was thus advancing in a career of prosperity and reputation, a tragical incident was very near depriving his country of his future services. This was the conspiracy of the Pazzi, a numerous and distinguished family in Florence, the rivals of the house of Medici. The instigators of this foul conspiracy, of which the object was the assassination of Lorenzo and his brother, were pope Sixtus IV. and his nephew, cardinal Riario: and the archbishop of Pisa, Salviati, was the principal agent in the horrid design. Giacopo de Pazzi, the head of that family, gave his name and assistance, and several persons of desperate character undertook to aid in the execution. Nothing could exceed the atrocity of the plan which was to assassinate the two brothers, while they were partaking of the hospitality of Lorenzo; but the absence of Giuliano, on account of indisposition, obliged the conspirators to postpone the attempt. Thus disappointed, another plan was to be adopted, and on further deliberation it was resolved that the assassination should take place on the following Sunday, in the church, at the instant of the elevation of the host.

The immediate assassination of Giuliano was committed to Francesco de Pazzi and Bernardo Bandini, and that of Lorenzo had been intrusted to the sole hand of Montesicco. This office he had willingly undertaken while he understood that it was to be executed in a private dwelling, but he shrunk from the idea of polluting the house of God with so heinous a crime. Two ecclesiastics were therefore selected for the commission of a deed, from which the soldier was deterred by conscientious motives. It was in the month of April 1478, the young cardinal Riario, apostolic legate, a guest in the palace of Lorenzo, proceeded to the church of the Reharata, since called "Santa Maria del Fiore," where the intended victims were present. The conspirators having taken their stations, waited with impatience for the appointed signal. The bell rang—the priest raised the consecrated wafer; the people bowed before it, and at the same instant Bandini plunged a short dagger into the breast of Giuliano. On receiving the fatal wound he took a few hasty steps and fell, when the other fiend, Francesco de Pazzi, rushed upon him with incredible fury, and stabbed him in different parts of his body, continuing to repeat his strokes even after he was apparently dead. Such was the violence of his rage that he wounded himself deeply in the thigh. The priests who had undertaken the murder of Lorenzo were not equally successful: they inflicted only a slight wound, which rather roused him to his defence, than disabled him. He instantly threw off his cloak, and holding it up as a shield in his left hand, with his right hand drew his sword, and repelled the assailants, who fled. Bandini came up with his dagger streaming with the blood of Giuliano, but was instantly laid dead by a servant of the Medici. In the mean time, the friends of Lorenzo assembled round him, and conducted him home in safety. An attack upon the palace of government where the magistrates were sitting, by other conspirators, failed of success, and the people attached to the Medici, collecting in crowds, put to death or apprehended the assassins, whose designs were thus entirely frustrated, with the exception of the death of Giuliano. Signal and instant justice was inflicted on the criminals. The archbishop of Pisa was hanged out of the palace window in his sacerdotal robes, and Giacopo de Pazzi, with one of his nephews, shared the same fate. Lorenzo did himself honour by his efforts to restrain the fury of the populace, and induce them to commit to the magistrates the farther pursuit of the guilty. The name and arms of the Pazzi family were suppressed, its members were banished, and Lorenzo rose still higher in the esteem and affection of his fellow-citizens. The pope, inflamed almost to madness by the defeat of his schemes, excommunicated Lorenzo, and the magistrates of Florence, laid an interdict upon the whole territory, and forming a league with the king of Naples, prepared to invade the Florentine dominions. Lorenzo appealed to all the surrounding potentates for the justice of his cause; and he was affectionately supported by his fellow-citizens. Hostilities began, and were carried on with various success through two campaigns. At the close of the year 1479, Lorenzo took the bold resolution of paying a visit to the king of Naples, and, without any previous security, trusted his liberty and his life to the mercy of a declared enemy. The monarch was struck with this heroic act of confidence, and a treaty of mutual defence and friendship was agreed upon between them. Sixtus, however, persevered in the war, till a descent upon the coast of Italy by Mahomet II. excited such an alarm, that he consented to a peace upon the submission of the Florentine deputies to his pontifical reprimands.

Another attempt was made to assassinate Lorenzo in a church in the month of May 1481, but the plot was happily discovered, and the agent and his accomplices were seized and executed. From this time he generally appeared in public, surrounded with friends as a guard, a circumstance which has been represented by his enemies as a symptom of tyranny. His political conduct as head of the Florentine republic was chiefly directed to the preservation of the balance of power among the Italian states. The death of Sixtus IV. freed him from an adversary who never ceased to bear him ill-will, and he was able to secure himself a friend in his successor Innocent VIII. He conducted the republic of Florence to a degree of tranquillity and prosperity which it had scarcely ever known before, and by procuring the institution of a deliberative body of the nature of a senate, he corrected the democratical part of its constitution.

Lorenzo distinguished himself beyond any of his predecessors in the encouragement of literature and the arts: his proficiency in Italian poetry would have conferred distinction even upon one who had no other merit to adduce. The productions of this great man are distinguished by a vigour of imagination, an accuracy of judgment, and an elegance of style, which afforded the first great example of improvement, and entitle him, almost exclusively, to the honourable appellation of the "restorer of Italian literature." His compositions are sonnets, canzoni, and other lyric pieces, some longer works in stanzas, some comic satires, and jocose carnival songs, and various sacred poems, the latter as serious, as many of the former are licentious. Some of these pieces, especially those of the lighter kind, in which he imitated the rustic dialect, became extremely

tremely popular. His regard to literature, in general, was teſtified by the extraordinary attention which he paid to the augmentation of the Laurentian library. Although the anceſtors of Lorenzo laid the foundation of the immenſe collection of MSS. contained in this library, he may claim the honour of having raiſed the ſuperſtructure. If there was any purſuit in which he engaged more ardently and perſevered in more diligently than the reſt, it was that of enlarging his collection of books and antiquities: for this purpoſe he employed the ſervices of learned men, in different parts of Italy, and eſpecially of his intimate friend and companion Angelo Politiano, who took ſeveral journies in order to diſcover and purchaſe the valuable remains of antiquity. "I wiſh," ſaid Lorenzo to him as he was proceeding on one of theſe expeditions, "that the diligence of Pico and yourſelf would afford me ſuch opportunities of purchaſing books, that I ſhould be obliged even to pledge my furniture to poſſeſs them." Two journies, undertaken at the inſtance of Lorenzo, into the eaſt, by Giovanni Laſcar, produced a great number of rare and valuable works. On his return from his ſecond expedition, he brought with him two hundred copies, many of which he had procured from a monaſtery at mount Athos; but this treaſure did not arrive till after the death of Lorenzo, who, in his laſt moments, expreſſed to Politiano and Pico his regret that he could not live to complete the collection which he was forming for their accommodation. On the diſcovery of the invaluable art of printing, Lorenzo was ſolicitous to avail himſelf of its advantages in procuring editions of the beſt works of antiquity corrected by the ableſt ſcholars, whoſe labours were rewarded by his munificence. When the capture of Conſtantinople by the Turks cauſed the diſperſion of many learned Greeks, he took advantage of the circumſtance, to promote the ſtudy of the Greek language in Italy. It was now at Florence that this tongue was inculcated under the ſanction of a public inſtitution, either by native Greeks, or learned Italians, who were their powerful competitors, whoſe ſervices were procured by the diligence of Lorenzo de Medici, and repaid by his bounty. "Hence," ſays Mr. Roſcoe, "ſucceeding ſcholars have been profuſe of their acknowledgments to their great patron, who firſt formed that eſtabliſhment, from which, to uſe their own claſſical figure, as from the Trojan horſe, ſo many illuſtrious champions have ſprung, and by means of which the knowledge of the Greek tongue was extended, not only through all Italy, but through France, Spain, Germany, and England; from all which countries numerous pupils attended at Florence, who diffuſed the learning they had there acquired throughout the reſt of Europe."

The ſervices of Lorenzo to the fine arts were not leſs conſpicuous than thoſe which he rendered to letters. Coſmo had collected all the moſt valuable remains of ancient taſte and ſkill that he could obtain. His treaſures were vaſtly augmented by Lorenzo, who propoſed to himſelf the improvement of modern art as the chief end of his magnificence in this point. Of the earneſtneſs with which Lorenzo engaged in this purſuit inſtances may be adduced. It is ſaid that thoſe who wiſhed to oblige him were accuſtomed to collect from every part of the world medals and coins, eſtimable for their age or their workmanſhip, ſtatues, buſts, and whatever elſe bore the ſtamp of antiquity. By his conſtant attention to this purſuit, and by the expenditure of conſiderable ſums, he collected, under his roof, all the remains of antiquity that fell in his way, whether they tended to illuſtrate the hiſtory of letters or the arts. It is not, however, on this account only that he is entitled to the eſteem of the profeſſors and admirers of the arts. He determined to excite, among his countrymen, a good taſte, and, by propoſing to their imitation the remains of the ancient maſters, to elevate their views beyond the forms of common life, to the contemplation of that ideal beauty which alone diſtinguiſhes works of art from mere mechanical productions. With this view he appropriated his gardens in Florence to the eſtabliſhment of an academy for the ſtudy of the antique, which he furniſhed with a profuſion of ſtatues, buſts, and other relics of art, the moſt perfect in their kind that he could procure. The attention of the higher rank of his fellow-citizens was incited to theſe purſuits by the example of Lorenzo; that of the lower claſs by his liberality. To the latter he not only allowed competent ſtipends, while they attended to their ſtudies, but appointed conſiderable premiums as rewards of their proficiency. To this inſtitution, more than any other circumſtance, Mr. Roſcoe aſcribes the ſudden and aſtoniſhing proficiency which, towards the cloſe of the 15th century, was evidently made in the arts, and which commencing at Florence, extended itſelf to the reſt of Europe. The gardens of Lorenzo de Medici are frequently celebrated as the nurſery of men of genius, but if they had produced no other artiſt than Michael Angelo Buonarotti, they would have ſufficiently anſwered the purpoſes of the founder. It was here that this great man began to imbibe that ſpirit which was deſtined to effect a reformation in the arts, and which, perhaps, he could have derived from no other ſource. The art of architecture he encouraged by the numerous buildings which he erected, or induced others to erect in Florence and its vicinity, after deſigns furniſhed by the ableſt artiſts. By theſe exertions he prepared the way for thoſe wonders which have rendered the age denominated from his ſon Leo X. one of the moſt ſplendid in the records of mankind.

Lorenzo, in his domeſtic concerns, deſerves conſiderable, but by no means unmixed praiſe. The licentiouſneſs which characterizes ſeveral of his poems is ſaid to have tainted his manners with reſpect to the female ſex. He was neverthelеſs a very affectionate and attentive father, ſolicitous for the inſtruction of his children, whom he placed under the care of Politiano, and he was fond of partaking in their ſports and amuſements. The exigencies of the republic in conſequence of its wars had obliged him to borrow, in his own name, large ſums, which the negligence or infidelity of his commercial agents and correſpondents rendered it difficult for him to repay; and a decree for the diſcharge of his debts out of the public treaſury was neceſſary to relieve him from his embarraſſments. From this period he determined to quit his mercantile concerns, for the improvement of his eſtates under his own eye. He had a numerous family, in the ſettling of which he was as ſucceſsful as an ambitious parent would generally deſire. His eldeſt ſon Piero, deſigned for his own ſucceſſor in the Florentine ſtate, was ſent, at the age of fourteen, to viſit the pope, and cultivate the family intereſt of Rome. The object of his cloſe connection with the pontiff, and the profound reſpect which he always teſtified for the holy ſee, was the attainment of the favourite point of his ambition, the elevation of his ſecond ſon Giovanni to the cardinalate, with the future proſpect of his filling the papal chair. By means of inceſſant applications, he prevailed upon the pope to confer upon Giovanni, at the age of thirteen, the high dignity of one of the princes of the Roman church, which was unqueſtionably a flagrant violation of decorum, diſhonourable to both.

"It was," says one of the biographers of Lorenzo, "a deserved consequence of this prostitution of ecclesiastical honours, that this cardinal, when arrived at the popedom, should, by his levity and extravagance, have given the immediate occasion to that defection from the church of Rome, which has so much reduced her power and authority." (For a farther account of this pontiff, the reader is referred to Leo X.) Of his other children, Giuliano became allied to the royal house of France, and obtained the title of the duke of Nemours; and his daughters married into noble families.

In the year 1488, Lorenzo's domestic comfort was much impaired by the loss of his wife. He was at this time absent at the warm baths, which he was often obliged to use, on account of a gouty complaint that severely afflicted him, and had made an early breach in his constitution. In the intervals of ease and health, he appears to have flattered himself with the expectation of enjoying the reward of his public labours, and partaking of the general happiness, which he had so essentially contributed to promote, in a peaceful and dignified retirement, enlivened by social amusements, by philosophic studies, and literary pursuits. These expectations were built upon the most substantial foundation, the consciousness that he had discharged his more immediate duties and engagements. "Having," says he, "now obtained the object of my cares, I trust I may be allowed to enjoy the sweets of leisure, to share the reputation of my fellow-citizens, and to exult in the glory of my native place." This prospect of relaxation and happiness he was not destined to realize. Early in the year 1492, the complaint under which he laboured attacked him with additional violence, and while the attention of his physicians was employed in administering relief, he contracted a slow fever, which escaped their notice, until it was too late effectually to oppose its progress. He sunk, almost before his attendants suspected danger, into such a state of debility, as totally precluded all hopes of recovery. Having performed the offices of the church, and adjusted with sincerity and decorum his spiritual concerns, he requested a private interview with his son Piero, with whom he held a long and interesting conversation on the state of the republic, the situation of his family, and the conduct which it would be expedient for him to pursue. When Lorenzo had relieved his mind from the weight of its important concerns, he became more sensibly alive to the emotions of friendship. At this moment Politiano entered his chamber: Lorenzo heard his voice, and raising his languid arms, clasped the hands of his friend in his own, and at the same time steadfastly regarded him with a placid and even a cheerful countenance. Deeply affected at this silent, but unequivocal proof of his esteem, Politiano could not suppress his feelings, but, turning his head aside, attempted, as much as possible, to conceal his sobs and his tears. Perceiving his agitation, Lorenzo still continued to grasp his hand, as if intending to speak to him when his passion had subsided; but finding him unable to resist its impulse, he relaxed his hold, and Politiano, hastening into an inner apartment, flung himself on a bed, and gave way to his grief. Having at length composed himself, he returned to the chamber, when Lorenzo enquired with great kindness why Pico of Mirandola had not once paid him a visit during his sickness. Politiano apologized for his friend, by assuring Lorenzo that he had only been deterred by the apprehension that his presence might be troublesome. "On the contrary," replied Lorenzo, "if his journey from the city be not troublesome to him, I shall rejoice to see him before I take my final leave of you." Pico came, prepared with a melancholy pleasure, to share, for the last time, the interest of his conversation. Lorenzo expressed his esteem for him in the most affectionate terms, professing that he should meet death with more cheerfulness after this last interview. He then changed the subject to more familiar and lively topics; and it was on this occasion that he expressed, with some degree of jocularity, his wishes that he could have obtained a reprieve, until he could have completed the library destined to the use of his auditors. This interview was scarcely terminated, when the haughty priest Savonarolo reminded him, that it was his duty to bear death with fortitude, "with cheerfulness," replied Lorenzo, "if such be the will of God." His vivacity as well as his resignation were perceptible almost to the last moment. Being asked, on taking a morsel of food, how he relished it, "as a dying man always does," was his reply. Having affectionately embraced his surrounding friends, and submitted to the last ceremonies of the church, he became absorbed in meditation, occasionally repeating portions of scripture, and accompanying his ejaculations with elevated eyes and solemn gestures of his hands, till the energies of life gradually declining, and pressing to his lips a magnificent crucifix, he calmly expired, in the forty-fourth year of his age. Few persons of his condition have filled so contracted a space of life with so much glory and prosperity.

In summing up his character, Mr. Roscoe says, he is "a man who may be selected from all the characters of ancient and modern history, as exhibiting the most remarkable instance of depth of penetration, versatility of talent, and comprehension of mind.——Of the various occupations in which Lorenzo engaged, there is not one in which he was not eminently successful: but he was more particularly distinguished in those which justly hold the first rank in human estimation. The facility with which he turned from subjects of the highest importance, to those of amusement and levity, suggested to his countrymen the idea that he had two distinct souls combined in one body. Even his moral character seems to have partaken, in some degree, of the same diversity; and his devotional poems are as ardent as his lighter pieces are licentious. On all sides he touched the extremes of human character, and the powers of his mind were only bounded by that impenetrable circle, which prescribes the limits of human nature."

After all that we have said of this great man, and his grandfather Cosmo, those who would rightly appreciate their talents and various virtues, will consult the life of Lorenzo De Medici by Mr. Roscoe, of which the first chapter is chiefly devoted to Cosmo, the remainder of the three volumes to Lorenzo and the fortunes of his house.

MEDICINA Musica, or the medicinal Power of Music; being an essay on the effects of singing, music, and dancing on the human frame, revised and corrected. To which is annexed, a new essay on the nature and cure of the spleen and vapours, by Richard Browne, apothecary at Oakham, in the county of Rutland, small 12mo. London, 1729.

This is the title of a small tract but little known; but as it is not devoid of merit, we shall give some account of the author's principles. We feared we should have had the old stories over again, of Orpheus, Linus, Amphion, and Terpander; but their names do not once occur in the work. The author does not ascribe any miraculous powers to music, as the Greeks, the Chinese, and the Arabians have done; who pretend to cure many diseases with the instrument called *Oüd*, resembling our lute: he only points out its mechanical effects on the nerves and animal spirits. He is moderate in his demands, and modest in his assertions. It is not elaborate composition,

composition, or exquisite performance, that is required to operate the effects which he describes; but the *dulce linimen* of Horace.

The gentle exercise of the lungs in singing, as well as the gratification of the ear in hearing sweet tones well accented, are among the prescriptions. And for this he only requires the patient to have an ear well organized, and the vocal performance to consist of gay and lively strains, so that the body and the mind may be reciprocally affected by the production and sensation of sound. As the motion of the blood is accelerated or retarded during the rise or fall of the mercury in the barometer; so in singing, the pressure of the air upon the lungs is greater than in common respiration.

The author supports his opinions ably and anatomically. He seems to have loved and understood music, though he never speaks of it with the enthusiasm of a rapturist.

Among the possible evils of too frequent and too violent exercise of the lungs, we wish the author had cautioned parents not to let their children, whatever disposition they may discover for singing, begin to exercise the voice seriously in difficult songs, or *solfeggios*, till arrived at their teens: as we have frequently known a promising voice sung away, by tearing and straining the vocal organ beyond its power. Let them hum a tune, or sing a light and pleasing ballad if they please; but leave different intervals, and long and high notes, to a more robust and mature age.

In asthmatic complaints, when the tone of the stomach is relaxed, and appetite fails; and in nervous disorders, as music raises the spirits, and diverts our attention from ourselves and our woes, real or imaginary, singing is not only amusing but salutary.

The author, however, seems to think that nervous and low-spirited persons should refrain from pathetic, melancholy, and languid airs, which, instead of exhilarating and enlivening the spirits, rather tend to their depression. But on the contrary, in affliction, pain, and sorrow, as well as in hypochondriac and calamitous cases, when gay and lively music is to the last degree offensive, we rather enlist with those who think grave music, if it cannot radically cure, can sooth, alleviate, and afford a temporary relief.

And among the medicinal effects of modern music that border on the marvellous, we read in the memoirs of the Acad. des Sciences at Paris, that a musician was cured of a violent fever, by a concert of well selected and well executed music in his bed-chamber. And the effect which Farinelli's singing had on Philip V. king of Spain, who like Saul seemed to have been troubled with an evil spirit, has never been disputed.

As to the author's *Medicina Gymnastica*, as a specific for spleen, vapours, and hypochondriac affections, we shall leave the consideration of these mysterious disorders to the profound sons of Æsculapius, who peradventure may be perfectly acquainted with their nature and existence. Mr. Browne, who has not defined them very clearly, prescribes, however, after other preparatory medicines, dancing to a good band of music for the completion of the cure. And as the music is meant to exhilarate and excite motion, the whole process seems reduced to the two most simple of all Hygeia's agents, *Air* and *Exercise*.

To these Armstrong adds *Sun-shine*.

"Cheer'd by thy kind invigorating warmth,
We court thy beams, great majesty of day!
If not the soul, the regent of this world,
First-born of heaven, and only less than God!"

MEDICINAL Waters. See Waters.

Medicinal *Sacculus*. See Sacculus.

MEDICINE, Medicina, from *mederi, to heal* or *cure*, is the art of restoring health to the sick.

It must be obvious, from a slight consideration of the subject, that various and complicated knowledge must conspire to give perfection to this art. It is not from the labours of an individual, though he were an Esculapius, nor even from the united collections of an age, that the nature and means of curing the disorders of the animal frame can be fully ascertained. For, to trace the matter in detail, it is necessary to be previously acquainted with the structure of the animal machine, or with the *anatomy* of the body; and likewise with the uses and actions of its various organs, in a state of health, the knowledge of which constitutes the science of *physiology*. But to the proper cultivation of this science, a previous knowledge of many other departments of science is absolutely necessary. Almost every branch of natural philosophy, indeed, contributes to the explanation of the functions of the animal economy. The uses of the eye are intelligible only upon the principles of *optics*, as applied to inorganic instruments; the functions of the ear upon those of *acoustics*; and the various mechanical operations of the body, such as those of muscular motion, the circulation of the fluids, the action of respiration, &c. upon the common principles of *mechanics* and *hydrostatics*: not to mention the numerous changes in the combinations and properties of the fluids; in the blood, as it passes through the lungs; in the food and drink, under the process of digestion; and in the various secreted fluids, as the urine, milk, bile, &c.; for the elucidation of which, the science of *chemistry* lends its aid. Upon these branches of knowledge the foundation of medicine is laid; but the superstructure requires many additional materials for its erection. The animal machine differs materially from all other examples of mechanism; principally in the possession of a self-sustaining and self-moving power, upon which alone the operation of every external influence must be directed; and from which result many phenomena, that belong exclusively to its constitution, and are inexplicable on any of the principles of mechanical or chemical philosophy: but it differs likewise, secondarily, in the circumstance that its motions are not (as in other machines) exposed to our view; that we cannot remove, repair, and renew, (as in them,) those parts or organs which become inadequate to their functions, and cannot suspend the motion of the whole but for a moment, without the imminent risk of stopping it for ever. Hence then, in addition to the principles of mere mechanism, the study of the animal constitution includes a series of minute observations on those phenomena, which are the result of *life*; and this study is necessarily rendered more obscure and difficult, from the circumstance last alluded to: for the internal operations of the vital machine, not being directly cognizable, can only be ascertained by indirect inference from external and obvious signs or symptoms. These signs or symptoms, therefore, are the sole object of the examination of the practisers of the art of medicine, and the sole guides of their proceedings. But as the existence and the nature of disease are known only by a comparison of those signs, which are exhibited by the body in health, with those which occur in disease; so the study of symptoms includes not only the science of *pathology*, but also a knowledge of the various *temperaments*, as they have been called, or of those various appearances of the structure, complexion, size, strength, &c. which are all compatible with health. (See Temperament.) The signs of the respective diseases of the different organs of the body we have detailed under their proper appellations, in the

the various articles in *medicine* and *ſurgery*; and a ſeries of the ſigns which are to be inveſtigated, as the indications of diſeaſe in general, will be found under the article DISEASE.

Poſſeſſed, however, of this knowledge, we ſhould ſtill be little more than uſeleſs, though learned, ſpectators of the phenomena of diſeaſe, if we were ignorant of all means of controlling the actions of the vital power. The art of medicine, then, obviouſly requires alſo a knowledge of the various productions of the material world, and of their properties, *i. e.* their agency upon the animal ſyſtem: for theſe productions afford the inſtruments by which alone art can effect any phyſical change in its condition. A ſeries of ages would be requiſite to teach mankind the phyſical properties of the animal, vegetable, and mineral ſubſtances, by which they are ſurrounded; and the nature of many of them could only be aſcertained by accidental trials, from the fatality, injury, or benefit derived from which, a ſlow but multiplying experience would ultimately ariſe. "Hæc ſimiliaque cum quotidie inciderent, diligentes homines notaſſe, quæ plerumque melius reſponderent; deinde ægrotantibus ea præcipere cæpiſſe: ſic medicinam ortam, ſubinde aliorum ſalute, aliorum interitu, pernicioſa diſcernentem a ſalutaribus." (Celſus. Præf.) The knowledge of the *materia medica* has thus been gradually brought to that comprehenſive extent, in which it exiſts at preſent, by a long ſeries of experiments, aided by the reſearches of travellers and naturaliſts, and by the diſcoveries and combinations of chemiſts.

The progreſs of the art of medicine, however, as Celſus has intimated, was the reverſe of the foregoing ſtatement. "Repertis deinde medicinæ remediis, homines de rationibus eorum differere cæpiſſe; nec poſt rationem, medicinam eſſe inventam; ſed poſt inventam medicinam, rationem eſſe quæſitam." (Loc. cit.) The hiſtory of the progreſs of medicine is, in fact, principally a hiſtory of thoſe reaſonings, or hypothetical ſyſtems, adopted by different individuals and their followers; and theſe conſiſted chiefly in transferring to the ſcience of life the doctrines of the collateral departments of philoſophy, which were ſucceſſively cultivated, as the following ſketch will evince.

MEDICINE, *Hiſtory of*. The hiſtory of medicine has for its object to deſcribe the origin and progreſs of the art, and to inveſtigate the cauſes and conſequences of the different revolutions which it has undergone.

Some authors have waſted much time and learning in attempting to depict the firſt origin of phyſic. Thus Schulze, a writer of great erudition, who was profeſſor at Altorf in the beginning of the 18th century, has traced it to the fall of man; ſhewing, with great gravity, what obſervations Adam and Eve were likely to make on the ſubject of their natural appetites, and the evacuations which followed their indulgence; what a rich ſtore of phyſiological knowledge they would collect, "quum ſe mutuo contemplarentur, quum amplecterentur, coirent;" and how probable it is, that Adam, yielding to the neceſſity of the occaſion, "laboranti amicæ, obſtetricias manus adhibuiſſe, ſicque chirurgiæ primam forte operationem exercuiſſe!" Even Le Clerc thinks it neceſſary to diſcuſs the queſtion, "Si la médécine eſt venue immediatement de Dieu?" and to ſhew, that the firſt man muſt have been alſo the firſt phyſician. And Brambilla, a ſurgeon of ſome repute at Vienna, aſſerts that Tubal Cain was the inventor and manufacturer of ſeveral ſurgical inſtruments; whence he endeavours to prove the greater antiquity of ſurgery!

It is evident, however, that medicine muſt have had a very early origin: for mankind, even in the moſt uncivilized ages of the world, would ſoon be led to remark the more or leſs agreeable, and more or leſs ſalubrious, qualities of the different articles of their food; and expoſed, as they would be, in the common courſe of things, to a variety of accidents, they would, by degrees, learn the means of alleviating the pain, or averting the conſequences of the more uſual external injuries. They would thus, in proceſs of time, form to themſelves certain dietetic maxims and rules, for the treatment of thoſe diſeaſes to which they found themſelves liable. Their materia medica would probably, at firſt, conſiſt of only a few herbs, which they had diſcovered to be efficacious in ſuppreſſing hemorrhage, and in healing wounds, or to which they imputed virtues, real or imaginary, in the cure of internal complaints; but all the concomitant circumſtances, under which they had obſerved recovery, in any doubtful caſe, to take place, would be regarded as indiſpenſable in every ſimilar caſe, and would be imitated accordingly. "Tunc non ſanabat medicina," as Meibomius ſhrewdly remarks, "ſed quidquid videbatur ſanaſſe erat medicina." Unacquainted, however, with the economy of the human body, and unable, for the moſt part, to trace the progreſs of diſeaſe, they would aſcribe the more fatal internal diſorders to the powers of ſorcery, or to the wrath of thoſe deities whom they had been taught to fear; and would reſort, for their cure, to thoſe rites and ceremonies by which they conceived they could break the charm, and pacify the offended gods. Hence would ariſe various ſuperſtitious practices, which would be handed down from one generation to another, and of which the prieſts and magicians of the communities would gladly avail themſelves, as affording them the means of extending their influence. Such we may conceive to have been the origin of the medical art; and ſuch nearly is its condition at the preſent day, among the ſavages of Africa and America, New Holland, Zealand, &c. See Winterbottom's Account of the native Africans in the Neighbourhood of Sierra Leone, vol. ii. Millar's Diſquiſitions in the Hiſtory of Medicine.

The Egyptians appear to have been the firſt nation which cultivated medicine in a ſyſtematic manner. Thouth, or Taaut, (the *Hermes Triſmegiſtus* of the Greeks,) who had been, according to Diodorus, the ſecretary of Oſiris, had divine honours paid him, as the inventor of letters, and of all uſeful arts and ſciences. His doctrines were collected, after his death, into a book, to which the title of "Embre" (*Scientia Cauſalitatis*) was given. A great part of this work conſiſted of medical precepts, which the phyſicians or prieſts were bound to obſerve ſtrictly. If they followed the directions, and the patient happened to die, they were held free from blame; but if they deviated in any manner from the rules laid down, they were puniſhable with death, whatever might be the iſſue of the caſe. Another of the Egyptian deities, Apis, is mentioned by ſome as the inventor of medicine; but greater influence is attributed to Serapis, whoſe moſt ancient temple was at Memphis, and who was worſhipped by the Greeks, as well as Egyptians, as preſiding over health. In whatever way theſe divinities may be ſuppoſed to have firſt attracted the adoration of the people, it is certain that the prieſts, from among whom the ancient kings of Egypt were choſen, appropriated to themſelves the functions of the medical art. The chief prieſts exerciſed what was conſidered as the higher branch of the profeſſion, which conſiſted of magic rites and propheſyings. They are the wiſe men and magicians of whom Moſes ſpeaks, and they appear to have been very expert in their tricks. On the *Paſtophori*, or image-bearers, who were an inferior order of the prieſthood, devolved the taſk of ſtudying the ſix hermetical

metical books on medicine. Theſe treated of the ſtructure of the body, of diſeaſes in general, of ſurgical inſtruments, of materia medica, of diſeaſes of the eyes, and of diſeaſes of women. It was the office of the chief prieſts to prognoſticate the courſe and event of the diſeaſe, while the paſtophori applied the remedies as directed in the ſacred books. As the rank of the Egyptian prieſts was hereditary, as the ſon received and obeyed implicitly the inſtructions of the father, and as their knowledge was communicated to none but thoſe who had been adopted into their order, it is evident that their medical knowledge would remain nearly ſtationary. It was obviouſly their intereſt to teach the people, that all diſeaſes proceeded from the immediate agency of the gods, and were to be cured only by ſacrifices and offerings. They concealed their art under the forms of religious ceremony, and conſequently we know very little concerning the details of their practice. Judging, however, from the analogy of other nations, we may infer that they left the cure of diſeaſes, in a great meaſure, to nature; and were content with promoting the diſcharges, which ſeemed to be indicated. This opinion is in ſome degree confirmed by the remarkable circumſtance which Ariſtotle mentions, (Polit. lib. iii.) *viz.* that it was contrary to their rules to venture upon any active treatment before the fourth day of the diſeaſe. We have the teſtimonies of Diodorus and Plutarch, that incubations were practiſed in the temples of Iſis and Serapis; and we learn from Pliny (lib. viii. c. 46.), that predictions of life and death were delivered in thoſe of Apis.

In the time of Herodotus, the ſtate of phyſic in Egypt ſeems to have been ſomewhat altered. According to this hiſtorian, "every diſtinct diſtemper had its own phyſician, who confined himſelf to the ſtudy and cure of that, and meddled with no other; ſo that all places were crowded with phyſicians; for one claſs had the care of the eyes, another of the head, another of the teeth, another of the ſtomach, and another of occult diſeaſes." But Herodotus would ſcarcely have ſpoken thus of the prieſt-phyſicians. We muſt therefore ſuppoſe that his deſcription applies to the exoteric practice of medicine, as profeſſed by Jatraliptæ and others; and we are inclined, notwithſtanding the dogmatical commentary of Warburton, to put a ſomewhat ſimilar interpretation on the paſſage of Geneſis (c l v. 2.), in which it is ſaid, that "Joſeph commanded *his ſervants, the* PHYSICIANS, to embalm his father; and the PHYSICIANS embalmed Iſrael." On the ſtrength of this uſe of the word *phyſicians*, the author of the divine legation (b. iv. § 3) has amuſed himſelf with forming an ideal picture of "the grandeur, luxury, and politeneſs" of the Egyptian people; and the writer of the article MEDICINE in the Encyclopedia Britannica has haſtily concluded that the firſt phyſicians of Egypt were not of the order of prieſts; but, when we conſider what muſt have been the ſtate of medicine in Joſeph's time; and when we find, that, long afterwards, the prieſts of the Jews were, properly ſpeaking, their only phyſicians, it will at once appear, how abſurd and untenable the above cited tranſlation of the original text is. It is far more probable, and it is certainly more conſonant with all that we have learnt concerning Egyptian hiſtory, to believe that the רופאי, whom Joſeph ordered "to embalm his father," were merely *embalmers*, or, as we might term them, *undertakers*. So, in fact, they are deſignated in the ſeptuagint; Και προσεταξεν Ιωσηφ τοις παισιν αυτου, τοις ενταφιασταις, ενταφιασαι τον πατερα αυτου. Και ενεταφιασαν δι ενταφιασται τον Ισραηλ. We know pretty accurately in what manner the ceremony of embalming was performed, and in what degree of eſtimation the perſons who executed the office were held; we know, too, that among the ancient Egyptians, there was a great diviſion of labour, and that no one was allowed to meddle with the trade or profeſſion of another; it is, therefore, not very likely that, if Joſeph had been ſo affluent as to retain a number of phyſicians in his ſuite, as Warburton ſuppoſes, they would have condeſcended, or been permitted, to embalm the body of his father. From the diſtribution of medical practice, as deſcribed by Herodotus, however, one might be diſpoſed to infer, that the Egyptians had already made conſiderable advances in the art; but as they were, in a great meaſure, debarred from all opportunities of acquiring anatomical knowledge, by the horror that purſued every one who cut open a dead body; and as they laboured, beſides, under many other reſtrictions in the cultivation of the ſcience, this could not poſſibly have been the caſe. That the Egyptian phyſicians were even very unſkilful in the treatment of external complaints, is proved by what the author juſt mentioned relates (lib. iii. c. 129.) concerning their inability to cure a common luxation of the foot, which Darius, the ſon of Hyſtaſpes, had met with in hunting. They appear, however, to have been acquainted with the powers of ſome valuable remedies, as of ſquills in dropſy, and of iron as a tonic in cachectic diſeaſes.

Medicine was eſtabliſhed on nearly the ſame footing among the Jews, as among the Egyptians. The prieſts, forming the only learned claſs, conſtituted themſelves the ſole judges and phyſicians of the people. Diſeaſes were believed to proceed from the wrath of "a jealous God;" and prayer was the chief means employed for their removal (Gen. xx. 17. Numb. xii. 13.); an immediate revelation to Moſes even declares, that if the people would give ear to the commandments of the Lord, and keep all his ſtatutes, he would put none of thoſe diſeaſes upon them which he had brought upon the Egyptians, for it was the Lord that healed them. (Exod. xv. 26.) It would appear, however, from different paſſages of the Pentateuch, and, in particular, from the enumeration of the different ſigns and varieties of leproſy, in Leviticus xiii., that the lawgiver of the Jews muſt have been, at leaſt, a very accurate obſerver. Some perſons have concluded, that he muſt have been alſo deeply ſkilled in chemiſtry, from his being able to diſſolve the golden calf, in the wilderneſs, and from his changing the bitter waters of Marah to ſweet, by means of a certain wood; but without more particular information reſpecting the means which he employed on theſe occaſions, it is impoſſible to form any accurate eſtimate of his chemical proficiency. In later times, the *prophets* of the Jews ſignalized themſelves by healing the ſick, raiſing from the dead, and occaſionally denouncing the infliction of diſtempers on thoſe who had rebelled againſt the law of God.

Recent reſearches have ſhewn, that, at a very early period of hiſtory, the inhabitants of Hindooſtan had made great progreſs in ſeveral branches of phyſical ſcience, but there does not appear to be any reaſon for believing that in the art of curing diſeaſes, they were ſuperior to the ſurrounding nations. According to Strabo (lib. xv.), they truſted chiefly to diet, and to external applications; the ſuperintendance of the ſick was committed in the towns to a particular deſcription of magiſtrates, under whoſe inſpection the Samaneans (Σαμαναιοι) were permitted to practiſe. A law prevailed, that whoever diſcovered a poiſon, was bound to keep it ſecret till he had found an antidote to it; if he ſucceeded in diſcovering the latter, he was rewarded with great honours; but if he made known the poiſon without the antidote, he was puniſhed with death.

Under the deſpotic government of China, whatever its admirers may chooſe to ſay, and whatever degree of antiquity they may aſcribe to its inſtitutions, it was utterly impoſſible

poſſible that the liberal arts could attain any high improvement. The medical code, which is aſcribed to Hoangti, and ſaid to have been compoſed 4000 years ago, but which has been proved to be of much later origin, forms the guide of the Chineſe phyſicians. Formerly there were public ſchools in different parts of the empire, in which medicine was taught in conjunction with aſtrology; but theſe no longer exiſt; and the art itſelf, as we learn from ſir George Staunton and other late travellers, is in a very degraded ſtate. The *Specimen Medicinæ Sinicæ*, for which we are indebted to Cleyen, ſufficiently proves that the Chineſe were never acquainted with its fundamental principles.

There is a ſtriking coincidence between the accounts which have been given of the medical divinities among the Greeks, and thoſe of the Egyptians, though it may be doubted whether the Greeks derived their knowledge of the art from the latter people. Like the Iſis and Oſiris, Apollo and Minerva became the gods of phyſic in Greece, and Orpheus, who was ſaid to be the ſon of Apollo and Calliope, performed the part of Thouth; inſtructing his countrymen in the myſteries of religion, in poetry, and in medicine. According to ſome chronologiſts, however, Melampus is reported to have flouriſhed conſiderably before his time, and to have diſtinguiſhed himſelf by his medical ſkill; of which he gave a remarkable proof in the cure of the daughters of Prœtus, king of Argos, who were attacked with leproſy and madneſs. Afterwards it would appear that all the chief heroes of Greece, and particularly thoſe of the Argonautic and Trojan expeditions, were more or leſs verſed in the phyſical art; in which they are ſaid to have received their inſtruction from Chiron the Theſſalian, ſurnamed the Centaur. Cephalus, Æſculapius, Melanion, Neſtor, Amphiaraus, Peleus, Telamon, Meleagrus, Theſeus, Hippolytus, Palamedes, Ulyſſes, Meneſtheus, Diomedes, Caſtor, Polydeuces, Machaon, Podalirius, Antilochus, Æneas, and Achilles, are all mentioned by Xenophon as the pupils of Chiron. Of theſe by far the moſt celebrated is Æſculapius, or Aſclepios, the reputed ſon of Apollo and Coronis. He was probably a Theſſalian prince; and he is deſcribed as particularly ſucceſsful in the cure of external diſeaſes. That, indeed, his merits muſt have been very extraordinary for the age in which he lived, ſeems proved by the fable, that Jupiter was obliged to remove him from the world, to prevent the growing indifference of mankind towards the gods, and the deſolation of Pluto's kingdom. Some time after his death, divine honours began to be paid him; in conſequence, chiefly, of his deſcendants devoting themſelves to the medical profeſſion; pretending to have derived their knowledge immediately from him, and aſcribing all the cures which they effected to his direct influence. His ſons, Podalirius and Machaon, have acquired a durable celebrity from the mention which the author of the Iliad has made of their ſurgical ſkill.

From the Trojan war till the age of Hippocrates, the art of medicine continued chiefly in the hands of the prieſts, who exerciſed it for their own profit in the temples of the gods. In conformity with the ſuperſtitious character of the age, the patients were taught to expect a cure, or at leaſt to learn the means of obtaining it, in dreams, for which they were previouſly prepared, or rather ſtupefied, by a courſe of impoſing ceremonies. The temples were generally ſituated in the neighbourhood of rivers, or mineral ſprings, and in elevated ſituations, where the influence of the freſh air, and the beauty of the ſurrounding proſpects, were likely to excite cheerful ideas, and to conduce to the recovery of the patient. Bathing was an indiſpenſable part of the initiatory proceſs; and this, conjoined with the ſtrict abſtinence which was enforced, doubtleſs often effected a cure. When recovery took place, the patients were led, from gratitude, to preſent various offerings to the deity of the place; ſometimes pieces of money were thrown into the ſpring where they had bathed, or from which they had drunk; at other times drawings and images of the diſeaſed parts, or tablets deſcriptive of the diſorder and cure, together with the names of the patients, were ſuſpended in the temples. Theſe narratives, ſome of which have been reſcued from oblivion by the induſtry of Grüter (Corp. Inſcript.), muſt have doubtleſs contributed to the progreſs of the art, and ſupplied the ſucceſſive generations of prieſts with ſome uſeful practical obſervations. The temples in which they were recorded, particularly thoſe of the Aſclepiades, became, in fact, ſo many medical ſchools, differing however from one another, and that often materially, in their doctrines and practice. Thus, the Cnidian ſchool diſtinguiſhed itſelf by its ſtrict empiriciſm; while that of Cos had more of a dogmatical character, laying much ſtreſs on the knowledge of the exciting cauſes, and the prognoſis of diſeaſe, and purſuing a more methodic and rational mode of treatment. The former produced Euryphon, the author of the Γνωμαι Κνιδιαι, and Cteſias, of whoſe Perſian hiſtory ſome fragments have been preſerved by Photius; in the latter was developed the genius of Hippocrates.

At firſt, they were only the actual deſcendants of Æſculapius who were inſtructed in the art: afterwards other perſons were admitted as pupils, having previouſly undergone a particular initiation, and bound themſelves by an oath to conform to the rules of the Aſclepiades. Some philoſophers of comprehenſive genius, however, accuſtomed to ſpeculate on the origin of things, the nature of man, &c. had already begun to extend their reſearches to medicine, and ſucceeded in reſcuing the ſtudy, to a certain degree, from the dominion of the prieſts. Of theſe benefactors of their race, no one is more deſerving of mention than Pythagoras, who, after viſiting Egypt and India in queſt of knowledge, returned to his own country and eſtabliſhed the ſchool of Crotona. He applied himſelf to the ſtudy of the animal economy; introduced a regular ſyſtem of dietetics; and did not neglect the practice of medicine. His attempts to explain every thing by the power of numbers, were, indeed, ſufficiently ridiculous; and his therapeutical maxims differed ſcarcely from thoſe of the temples; but the rules of regimen which he inculcated were, generally ſpeaking, very judicious, and implied conſiderable powers of obſervation; though they have, no doubt, been carried to an extravagant length by his followers. Among his immediate diſciples, Alcmæon is celebrated as the inventor of anatomy; and though his knowledge of the internal ſtructure of the human frame may be diſputed, yet the concurring teſtimonies of Ariſtotle, Diogenes, and Plutarch, abundantly prove that he made no inconſiderable figure as a comparative anatomiſt. He is alſo the author of the firſt theory of ſleep. "When the blood," he ſays, "returns into the larger blood-veſſels, ſleep is induced: when it is again diſtributed, waking occurs; but a complete congeſtion is followed by death." (Plutarch de Plac. Philoſ. lib. v. c. 23.) Empedocles was another diſtinguiſhed adherent of the Pythagorean ſect. See Empedocles.

Beſides theſe philoſophers, and the Aſclepiadæ, there were, at this period, other perſons who devoted themſelves to the profeſſion of phyſic, and who occaſionally were remunerated by a fixed ſalary. Thus, Democetes of Crotona was retained at the court of the Samian tyrant, Polycrates, with an allowance of two talents yearly: being afterwards taken priſoner, and carried as a ſlave into Perſia, he acquired great repute by curing Darius of a ſprained foot, after the

Egyptian

Egyptian phyſicians had failed; and alſo by his ſucceſsful treatment of a tumour of the breaſt, under which Atoſſa, the daughter of Cyrus, and wife of Darius, had laboured for a conſiderable time. (Herod. iii. 133.) Such practitioners, from their wandering lives, were ſometimes deſignated by the name of περιοδευται. Of this claſs, one of the moſt conſpicuous was Acron of Agrigentum, the contemporary and rival of Empedocles, reſpecting whom Pliny has fallen into a ſtrange error, in deſcribing him as the founder of the empiric ſect "under the ſanction of Empedocles." According to Diogenes, he was the author of ſome books on medicine and dietetics, written in the Doric dialect; and he ſignalized himſelf at Athens, in the time of the great plague, by introducing the practice of fumigations (πυρ καιοντα παρακαλειν τοις νοσουσιν), and thus affording relief to many. (Plut. de Iſid. et Oſir.) The *gymnaſia* of ancient Greece ſeem alſo to have contributed to the improvement of the art. It belonged to the gymnaſiarch, or *palæſtrophylax*, to regulate the diet of the youths who were trained in theſe ſeminaries; the ιατραλειπται were preſumed to be converſant with diſeaſes; and it was the buſineſs of the αλειπται to perform veneſection, to dreſs wounds, fractures, &c. They were ſometimes called phyſicians. It was in theſe ſeminaries that the gymnaſtic ſyſtem of medicine originated, under the auſpices of Iccus of Tarentum, and Herodicus of Selymbria. See HERODICUS.

The firſt year of the eightieth Olympiad gave birth to Hippocrates, the ſecond of that name, who was deſtined to effect a greater revolution in medical ſcience than had hitherto been accompliſhed, and whoſe authority continued to be regarded with almoſt implicit veneration by his ſucceſſors, during a period of more than two thouſand years. "He ſaw," ſays Mr. Cabanis, "that too much, and yet not enough, had been done for medicine; and he accordingly ſeparated it from philoſophy, to which it had never been united by its true and reciprocal relation. He brought the ſcience back again into its proper channel, that of rational experience. However, as he himſelf obſerves, he introduced both theſe ſciences into each other, for he conſidered them as inſeparable; but he aſſigned to them relations which were altogether new. In ſhort, he freed medicine from falſe theories, and formed for it new and ſolid ſyſtems: this, he with juſtice ſaid, was to render medicine philoſophical. On the other hand, he elucidated moral and natural philoſophy by the light of medical ſcience. This we may, with propriety, call with him the introduction of the one into the other.

"The new ſpirit of improvement, which was thus communicated to medicine, reſembled a ſudden light that diſpels the phantoms of darkneſs, and reſtores to bodies their proper figure and natural colour. By rejecting the errors of former ages, Hippocrates learned more fully to avail himſelf of the uſeful part of their labours. The connection and dependence, both of the facts which had been obſerved, and of the concluſions which had been legitimately deduced from their compariſon, were now perceived with a degree of evidence, which, till then, had been unknown. All the diſcoveries were certainly not yet made; but from that moment inquirers began to purſue the only path which can conduct to them; from that moment, if they had been able to preſerve themſelves from deluſion, they would have poſſeſſed ſure means of eſtimating, with preciſion, the new ideas which time was deſtined to develope; and if the diſciples of Hippocrates had underſtood his leſſons well, they might have laid the foundation of that analytical philoſophy, by the aid of which the human mind will be henceforth enabled to create to itſelf, as it were, daily, ſome new and improved methods of advancement." Coup d'Œil ſur les Revolutions, &c. de la Médécine, 76—78.

Unfortunately, however, for the progreſs of the art, the diſciples of Hippocrates either did not "underſtand his leſſons," or, miſled by vanity, or other more ignoble paſſions, they ſoon deviated from the path which he had ſtruck out. Inſtead of purſuing quietly the obſervation of nature, they conſumed their time in framing fanciful hypotheſes to explain her operations: inſtead of ſtudying, in a ſincere ſpirit, the works of the maſter whom they profeſſed to worſhip, they ſhameleſsly falſified his writings, in order to adapt them to their own peculiar views, ſo that it has become, as we have already had occaſion to ſhew, (ſee HIPPOCRATES,) a matter of no ſmall difficulty to diſtinguiſh the genuine from the ſpurious compoſitions that have been aſcribed to the father of medicine. But, notwithſtanding theſe errors, it cannot be doubted, that the genius of Hippocrates exerted a highly beneficial influence on the minds of ſucceeding inquirers; and that, without his writings for a guide, the ſcience of phyſic would have remained, for a much longer period, in a ſtate of infancy. "Au lieu de ces ſyſtêmes, ſinon meurtriers, du moins ridicules, qu'a enfantés la médécine moderne pour les proſcrire enſuite, on y trouve des faits bien vus et bien rapprochés; on y voit un ſyſtême d'obſervations, qui encore aujourdhui ſert de baſe à l'art de guérir." D'Alembert, Melanges, iii. 271.

The Dogmatic ſchool, of which Hippocrates has erroneouſly been conſidered as the head, was founded by his ſons Theſſalus and Draco, and his ſon-in-law Polybus, who are the reputed authors of many of the books that now paſs under Hippocrates' name. Polybus is mentioned by Ariſtotle as the compiler, at leaſt in part, of the book "On the Nature of Man," which contains all the leading tenets of the Dogmatiſts, and which was regarded by Galen not as the compoſition of one individual, but as a collection of fragments by different writers. Applying the myſtical doctrines of the Platonic philoſophy to medicine, the Dogmatiſts proceeded upon the principle which has exerted ſuch baneful influence on the progreſs of ſcience in general, *viz.* "that where obſervation failed, reaſon might ſuffice." (De Arte. Ed. Foeſ. 1657. p. 6.) They accordingly were led to neglect the patient ſtudy of nature; and before they had collected a ſufficient ſtore of facts, they fondly imagined that they had laid the foundation of an incontrovertible ſyſtem. Hence it came, that, in their inquiries, ſophiſtry often uſurped the place of obſervation, and futile hypotheſis was preferred to experience. In this way aroſe a multitude of ſects, who contributed little or nothing to the advancement of the art, but, on the contrary, were daily miſleading their followers more and more from the right path of reſearch. It is therefore highly unjuſt to refer the origin of the Dogmatic ſchool to Hippocrates, in whoſe genuine writings it will be found that the moſt oppoſite principles are inculcated. For a more particular account of the doctrines of this ſect, ſee EMPIRIC.

About the ſame period, Eudoxus of Cnidos introduced the Pythagorean ſyſtem, and a modification of the Egyptian practice, in which he was followed by his diſciple Chryſippus. With the latter, cabbage and other vegetables were the favourite remedies; to purgatives and blood-letting he had an averſion. One of the moſt diſtinguiſhed men of the age, however, was Diocles of Caryſtus, whom Pliny (xxvi. 2.) ranks as almoſt equal to Hippocrates. He employed himſelf in comparative anatomy, and corrected many errors of his predeceſſors: like the two laſt mentioned phyſicians, he united the doctrines of Pythagoras with medicine; aſcrib-

ing

ing great influence to the number ſeven and its combinations. (Macrob. in Somn. Scip. i. 6.) He was alſo the inventor of a ſurgical inſtrument for the extraction of arrows, called after him *Diocleus graphiſcus*. His contemporary, Praxagoras of Cos, is not leſs deſerving of notice on account of his anatomical labours, being the firſt perſon who eſtabliſhed the diſtinction of arteries and veins, and who demonſtrated the abſence of *cotyledons* in the human uterus; whence Sprengel (Geſchichte der Arzneikunde, i. 549.) has with great plauſibility conjectured, that diſſections of the human ſubject could not have been, at that time, entirely unknown. Praxagoras alſo introduced the doctrine of the pulſe, and reduced the humoral pathology to a more regular ſyſtem: he made frequent uſe of veneſection, particularly in hemorrhage, and was a bold ſurgical operator; for he ſcrupled not, as Cælius Aurelianus informs us, to lay open the abdomen, and divide the *inteſtinum rectum*, in the iliac paſſion, in order to remove the accumulated fæces.

Many circumſtances had now concurred to favour the advancement of natural knowledge. The ſpirit of inquiry, which the early philoſophers had excited, was cheriſhed by the eſtabliſhment of ſo many rival ſchools; but, above all, by the number of learned men, who aroſe to adorn and inſtruct the world. Within the ſhort ſpace of a century appeared Ariſtotle, Pyrrho, Theophraſtus, Zeno, and Epicurus, all of them endowed with tranſcendent genius. and conſpicuous for their zeal in the cauſe of ſcience. The influence which they exerted on the character of their age was accordingly very great. While Ariſtotle applied himſelf, with the moſt ſignal ſucceſs, to all the branches of moral and phyſical reſearch, and his pupil Theophraſtus laid the foundation of true botanical ſcience; Zeno and Epicurus developed thoſe beautiful ſyſtems of ethics, which tranſported their contemporaries, and which ſtill, in ſome meaſure, divide the minds of men. However remote from medicine the ſpeculations of moraliſts may at firſt ſight appear, a little obſervation will teach us, that the phyſicians of almoſt every age have allowed themſelves to be carried along by the current of prevailing opinions. In the epoch of which we are now writing, the tenets of Pyrrho and Epicurus were eagerly ſeized upon by the empirical ſect, as favouring their peculiar views; while the ſtoical ſyſtem gave new ſtrength to the dogmatiſts, particularly by the introduction of the dialectic method.

The eſtabliſhment of a magnificent library and muſeum of natural hiſtory at Alexandria, and the liberal patronage which learning there received from the Ptolemies, rendered that city the chief reſort of men of ſcience from all parts of the world, and the great emporium of literature. In conſequence, the Alexandrian ſchool ſoon eclipſed all the rival ſeminaries, and produced a ſucceſſion of eminent phyſicians; among whom Herophilus and Eraſiſtratus are entitled to the firſt place, on account of their important contributions to anatomical knowledge. (See their reſpective articles.) It was in their time, and probably at Alexandria, that the memorable diviſion of the art into three branches took place: "Iiſdem temporibus, in tres partes medicina diducta eſt, ut una eſſet, quæ victu, altera quæ medicamentis, tertia quæ manu mederetur." (Celſ. l. i.) But, however much this diſtribution of practice was calculated to accelerate the progreſs of medical ſcience, in all its different parts, it does not appear that the immediate ſucceſſors of Herophilus and Eraſiſtratus turned the circumſtance to great account; though Celſus affirms, that ſurgery improved rapidly after its ſeparation. Lib. vii. Præf.

Of the eſtabliſhment and doctrines of the Empirical ſect we have already given a ſufficiently minute view under the proper article. We have there ſhewn how decidedly the principles of this ſchool were oppoſed to thoſe of the Dogmatiſts; and that there was ſomething more than a mere diſpute of words between them, as ſome writers maintain. Notwithſtanding, however, all their points of variance; notwithſtanding the violence and bitter animoſity which the contending parties diſplayed in their controverſies; it was found, that when they came to apply their reſpective principles to practice, and to determine on the treatment of diſeaſe, all differences, in a great meaſure, vaniſhed. Nor was this to be wondered at: for the dogmatiſts, though they indulged too much in hypothetical reaſoning, did not altogether neglect obſervation, and were conſequently more or leſs guided by the ſame leſſons of experience, on which the empirics founded their therapeutical maxims. The ſame remark will be found to apply to almoſt all the ſects which have acquired any conſequence in the medical world.

In the article laſt referred to, Heraclides of Tarentum has been mentioned as one of the adherents of the empirical ſchool; but he deviated from the ſtrict empirics in this reſpect, that he did not neglect the inveſtigation of the hidden and remote cauſes of diſeaſe. His practice in ſome of the moſt dangerous diſeaſes, as phrenitis, lethargy, cynanche, tetanus, and cholera, (for the deſcription of which we are indebted to Cælius Aurelianus,) ſeems to have been highly judicious. To the materia medica he contributed largely: he wrote a treatiſe on the compoſition of medicines, in which he obſerved the praiſeworthy maxim of noticing only ſuch remedies as he had adminiſtered himſelf. He is alſo reported to have poſſeſſed no inconſiderable ſkill in ſurgery; and, on the whole, he appears to have fully merited the eulogies of Galen and Aurelianus, the latter of which ſtyles him *empiricorum princeps*. After his death, the ſtudy of the materia medica took a new direction, in conſequence of the attention that was paid to the ſubject of poiſons and their antidotes, by the kings of Pergamus and Pontus. The antidote which was invented by the latter is well known, though its efficacy has never been proved. Even Serenus, who is in general ſufficiently credulous, ſeems to have had no very high opinion of its virtues.

> "Antidotus vero multis Mithridatica fertur
> Conſociata modis, ſed Magnus ſcrinia regis
> Cum caperet victor, vilem deprehendit in illis
> Syntheſin, et vulgata ſatis medicamina riſit." Cap. lx.

Nicander of Colophon, who was the contemporary of Attalus, king of Pergamus, acquired great fame as a grammarian, a poet, and a phyſician. Of his works, only the two treatiſes in verſe, entitled Θεριακα and Αλεξιφαρμακα, have been handed down to us. Though not abounding in poetical merit, they diſplay no mean acquaintance with natural hiſtory.

The Roman people, as Pliny aſſures us (xxix. 1.), had continued without phyſicians, if not without phyſic, during a period of 600 years. On the occaſion of a deſtructive epidemic, in the year 463 A.U.C. however, they ſent a deputation to the temple of Eſculapius at Epidaurus. Inſtead of an oracle, they received one of the ſacred ſerpents, and following the indication of its ſpringing from the ſhip upon the iſland of the Tiber, they there founded a temple to the god of medicine, and eſtabliſhed his worſhip on the ſame footing as at Epidaurus. Shortly afterwards, a temple was dedicated to the Grecian Hygeia, and the worſhip of Iſis and Serapis was borrowed from the Egyptians: but, beſides theſe, the Romans had certain medical deities quite peculiar to themfelves. For example, on the Palatine Mount, there was a temple of the goddefs Febris, who probably received divine honours from a prevalent dread of the difeafe. Tomafini, (in Grev. Thefaur. Roman. Antiquit. v. xii. p. 867.) has preferved the following infcription of a votive tablet to this goddefs:

"Febri divæ febri
Sanctæ febri magnæ
Camilla amuta pro
Filio male affecto p."

There was alfo a goddefs Offipaga, who prefided over the growth of the bones, and one ftyled Carna, who took care of the vifcera, and who had bean-broth and bacon offered to her, as being the moft nutritious articles of diet. (Macrob. Saturnal. lib. i. p. 123. ed. Ald.) The goddefs Mephitis, who is mentioned by Tacitus, as worfhipped at Cremona, had probably the fame attributes as Febris.

With refpect to the queftion, which was fo warmly debated in the beginning of the laft century, (*viz.* Whether the art of phyfic was exercifed by any other perfons than flaves, or freedmen, in the earlier periods of Roman hiftory?) we would obferve, that the probability is againft the fuppofition, that it was fo. Certain it is, that the inferior orders of the profeffion, thofe Greeks, for example, who were employed to perform venefection, to extract corns, or draw teeth, were all dignified with the title of *medici*, in the fame way as the Jatraliptæ were often ftyled ἰατροι. But that in time they raifed themfelves above this fervile condition, is abundantly proved by the honour of citizenfhip, and other privileges, which were conferred upon them. Archagathus is the firft perfon who is mentioned as having come to Rome, of his own accord, to practife the art of furgery. The fenate decreed him the freedom of the city, and purchafed for him a fhop in the Acilian crofsway; but his cruel operations—"fævitia fecandi urendique"—foon brought him into difrepute, and eventually led to his banifhment. Pliny, loc. cit.

In the 654th year A.U.C., or 100 years before the Chriftian era, Afclepiades, a native of Prufa in Bithynia, who had ftudied at Alexandria and Athens, came to Rome as a teacher of rhetoric: but not finding that profeffion fufficiently lucrative, he fuddenly turned phyfician, and by his confummate addrefs, in a fhort time, brought himfelf into great notice. The prototype of all fucceeding quacks, Afclepiades affected to contemn every thing that had been done before him—"omnia abdicavit; totamque medicinam, ad caufam revocando, conjecturam fecit;" he ridiculed Hippocrates for his patient obfervation of nature, and called his fyftem a *meditation on death*, θανάτου μελέτην. His fame, however, would have been incomplete, if he had not introduced a fyftem of his own. Accordingly, taking, for the bafis of it, the philofophy of Epicurus and Heraclides of Pontus, he attempted to explain all the functions of the human body, and all the operations of health and difeafe, by means of corpufcles and pores, ὄγκοι and πόροι. Anatomy was altogether neglected by him. In his practice, he profeffed to be guided by the maxim *tuto, celeriter, et jucunde:* but though he flattered the caprices of his patients, and foothed their complaints by the blandifhments of his rhetoric; yet we learn from Celfus (lib. iii. c. 4.), that he fubjected them to many fevere mortifications; keeping them, for inftance, feveral days without drink or fleep, in the early ftages of fever. That Afclepiades, however, poffeffed no mean talent for obfervation, is proved by his defcription of difeafes, and by the divifion of them into acute and chronic, which appears to have originated with him. The remedies which he employed were chiefly dietetical; but he was no enemy to phlebotomy, though he difcouraged vomiting and purgation: inftead of the latter he recommended clyfters. He was a great advocate for the efficacy of frictions, geftation, and other corporeal exercifes; and he fedulouﬂy prefcribed the ufe of cold water externally as well as internally; though he probably ingratiated himfelf with the Romans more by his free adminiftration of wine, in diforders where it had not formerly been allowed. Sprengel fuppofes him to have been the inventor of the fhower-bath, *balinea penfilis*. Pliny, xxvi. c. 3.

Themifon of Laodicea, a difciple of Afclepiades, adopting the leading doctrines of his teacher, founded upon them the Methodic fyftem. He difcarded the ftudy of remote caufes, the theory of critical days, &c. as wholly ufelefs; and maintained, that all that was neceffary for the phyfician, was an acquaintance with certain general conftituents of difeafe. In his practice he followed the footfteps of Afclepiades, firft famifhing his patients, and then endeavouring to obviate the preternatural condition, which he had induced. His fuccefs, however, would not appear to have been very great, if we are to credit the infinuation contained in the line of Juvenal,

"Quot Themifon ægros autumno occiderat uno."

The object which the Methodic fect had in view, feems to have been the fimplification of the theory and practice of the art. The inveftigations of the Dogmatifts refpecting occult caufes appeared to them to reft on too fallacious grounds; nor were they fatisfied with obferving the *concurfus fymptomatum*, like the Empirics: they therefore fteered a middle courfe between the two, taking for the bafis of their theory certain conditions of the fyftem, which are common to different difeafes (quædam morborum communia, κοινότητα); without confidering, as Sprengel well obferves, that thefe conditions of the body are as often, if not more frequently, concealed from view, than all the occult caufes of the Dogmatifts. The earlier adherents of this fyftem contended, that there were two general morbid conditions to which all difeafes were referrible, *viz.* a ftate of *conftriction*, and a ftate of *relaxation;* but they applied thefe terms not, as it would appear, in the modern acceptation, to particular organs, but to the body at large. Conformably to this view of difeafe, all that the practitioner had to do, was to find out, in each cafe, the morbid condition, and to apply his remedies accordingly: if it was a difeafe of conftriction, he prefcribed relaxing medicines; and if it was one of relaxation, he employed aftringents. But it was very foon difcovered, that thefe two ftates would not comprehend all difeafes: the Methodifts therefore invented a third common condition, which they called the *mixed* ftate. "We may form fome idea," Mr. Cabanis obferves, "of what they meant to defignate by the term *difeafes of conftriction*, though it is certainly not fo intelligible to men of fcience, as it appears to the uninformed clafs; we may alfo conceive the import of the phrafe *relaxed fibres;* but it is difficult to divine, what they could underftand by their *mixed fpecies*, or how they could apply to practice this fpeculative notion, which is fo very fubtle, as to elude all clear conception. Befides, is it not evident, that almoft all difeafes belong to the *mixed* clafs, or may be referred to it? For this word, if it fignify any thing, muft mean an *inequality of tone* in the different organs, or an *irregular diftribution* of the vital power. Now the majority of difeafes prefent the general phenomenon of a derangement of equilibrium,

brium, or irregular expenditure of living energy. In thoſe caſes, in which theſe deviations from the healthy ſtandard are leſs obvious, an obſerving eye may ſtill perceive them; and, perhaps, there is no diſeaſe in which a deficiency of equilibrium is not, in ſome degree, manifeſted, whether it be in the tone of the different organs, or in the exerciſe of life, and diſtribution of the ſenſibility of the ſyſtem. Thus then, the *mixed ſpecies* of the Methodic ſect, by comprehending every thing, becomes, in fact, applicable to nothing." Loc. cit. p. 100.

Notwithſtanding the juſtice of theſe ſtrictures, it cannot be denied, that the doctrines in queſtion had, in one point of view, a beneficial tendency, *viz.* by obliging phyſicians to ſtudy more attentively, than they had hitherto been accuſtomed to do, the different *indications* of diſeaſe. If the Methodiſts had applied themſelves to the inveſtigation of ſuch morbid conditions of the ſyſtem as were manifeſted by the ſymptoms; and if they had not raſhly attempted to ſimplify pathology, by ranging diſeaſes in two general claſſes, according to characters that were but partially applicable; their ſchool would have conduced ſtill more to the improvement of the ſcience of medicine. As to their mode of practice, it may be obſerved, that they wholly overlooked the healing powers of the ſyſtem, and, without regard to the peculiar circumſtances of the caſe, or the nature of the part affected, were ſolely intent on fulfilling thoſe general indications, that were conformable to their theory. It is true, that they paid particular attention to days; not, however, as connected with the doctrine of criſes, for which, as we have already hinted, the founders of this ſect entertained a marked contempt; but only as affording them a meaſure of the duration of the diſorder, and a guide for the method of treatment. In the firſt days, they followed the ſtarving ſyſtem; afterwards they purſued the ſuppoſed general indications of conſtricting, or of relaxing: during the exacerbation of the diſeaſe, they endeavoured to moderate the violence of it; during its decline, they ſupported the powers of the ſyſtem by nutritive diet. This was their mode of proceeding in all acute diſeaſes: but, in chronic complaints to which it was leſs applicable, they had recourſe to what they termed the μετασυγκρισις, or *reincorporation,* of which the profeſſed object was to reſtore the proper relations between the atoms and pores, and for which they prepared the patient by the αναληψις, or *reſumptive circle.* It was, in fact, little elſe than their practice in acute diſeaſes reverſed,—they firſt ſought to ſtrengthen the patient by a generous diet, and then they adminiſtered a ſucceſſion of violent remedies, to ſubdue the original malady. For the details of this mode of treatment, ſee Cæl. Aurel. Chron. i. c. 1. ii. c. 13. 29. &c.

Among the diſciples of Themiſon, one Theſſalus of Trallis, a man of low birth and coarſe manners, made himſelf conſpicuous by the ſhameleſs audacity with which he ſought to diſparage the labours of others—arrogating to himſelf the title of ιατρονικης, or *conqueror of phyſicians,* and that, it would appear, without the ſlighteſt pretenſions to either learning or talents. (Plin. l. xxix. c. 1.) He held forth, that he could qualify any one for a phyſician in the ſpace of ſix months, and actually ſucceeded in obtaining a great number of pupils; but it was from among the loweſt order of artiſans, ſuch as rope-makers, weavers, cooks, butchers, fullers, and ſuch like. Theſe he took with him to viſit his patients for the ſtipulated time, and then he conferred upon them the privilege of practiſing for themſelves. From his time it became the cuſtom for the Roman phyſicians to viſit their patients attended by all their pupils; in alluſion to which, we have the epigram of Martial:

> "Languebam; ſed tu comitatus protinus ad me
> Veniſti, centum, Symmache, diſcipulis.
> Centum me tetigere manus aquilone gelatæ:
> Non habui febrem, Symmache: nunc habeo!"

The methodic ſchool acquired much greater repute from the labours of Soranus and Cælius Aurelianus; the former a native of Epheſus, who had ſtudied at Alexandria, and came to Rome during the reign of Trajan; the latter an African by birth. Free from the prejudices, which had diſgraced his predeceſſors, Soranus cultivated the ſtudy of anatomy, and wrote a book on *the female organs of generation,* which is ſtill extant, and which diſplays conſiderable acquaintance with the ſubject. Many of his obſervations on diſeaſe ſhew, that he was poſſeſſed of great ſagacity and ſtrength of judgment. To Cælius Aurelianus, on the other hand, we are indebted for an account of his doctrines and practice, and for one of the beſt works on medicine, which have come to us from ancient times; written, it is true, in a barbarous ſtyle, but highly deſerving of peruſal on account of the accurate deſcription of diſeaſes, and the different methods of treatment, which it contains.

Anatomy and the other auxiliary ſciences, though they had been ſo much neglected by the methodiſts, were now receiving important additions from other quarters. Rufus of Epheſus, who lived in the time of the emperor Trajan, and whoſe works have been edited by our countryman, Clinch, applied himſelf zealouſly to the diſſection of animals, particularly of apes, and deſcribed from analogy the different organs of the human body. He traced the nerves from their origin in the brain, and divided them into thoſe of ſenſation and thoſe of voluntary motion; he pointed out the decuſſation of the optic nerves at the *infundibulum,* and he ſpeaks of the capſule of the cryſtalline lens, under the appellation ὑμην φακοειδης. The heart he believed to be the ſeat of life, of animal heat, and the cauſe of pulſation, and he ſhewed the difference of ſtructure and capacity between the right and the left ventricle. The ſpleen he held to be an uſeleſs organ. Marinus, whom Galen calls the reſtorer of anatomy, and to whoſe labours he was himſelf probably indebted for much of his knowledge on the ſubject, rendered ſtill greater ſervices to the ſcience. He inveſtigated the abſorbent ſyſtem with great care, and diſcovered the meſenteric glands; he diſtributed the nerves into ſeven pairs: the N. palatinus (then called the fourth pair) was firſt deſcribed by him; and he is ſaid to have been the diſcoverer alſo of the *par vagum,* which he termed the ſixth pair. His numerous writings have all periſhed.

The ſtudy of the materia medica, and of the other branches of natural hiſtory, was proſecuted with no leſs vigour; and we owe to this epoch the invention of many remedies, which are ſtill retained in our pharmaceutical ſyſtems. The elder Pliny, ſecond only to Ariſtotle in the univerſality of his genius, but ſurpaſſing even that great man in his inſatiable thirſt for knowledge, had collected in his Hiſtoria Mundi all that the ancients knew of natural ſcience. Dioſcorides of Anazarba, devoting himſelf to botany and materia medica, produced a work, which ſerved for a guide in theſe ſciences till a very late period. His deſcriptions of ſome of the more valuable drugs, ſuch as myrrh, ladanum, aſſafœtida, ammoniac, opium, ſquills, and their different preparations, are entitled to great praiſe. The efficacy of ſeveral remedies, which he recommends, has been admirably confirmed by later experience, ſuch as of the

the elm-bark in cutaneous diseases, of potash as a caustic, of the male fern against worms, &c. &c. Some of the contemporaries of Dioscorides, as Scribonius Largus, Xenocrates, and Andromachus, cultivated the materia medica, but with less success. To Menecrates, who lived in the reign of Tiberius, and who, according to an inscription in Montfaucon, appears to have been the author of 155 books, we are indebted for the invention of the *diachylon* plaister; and Damocrates is well known as the author of several complicated remedies, which bear his name. Herennius Philo, of Tarsus, is mentioned by Galen as the inventor of an anodyne composition, called, after him, Philonium, and which consisted of opium, euphorbium, and different aromatics; and Asclepiades Pharmacion was the introducer of numerous remedies from the animal kingdom, which, though long honoured with a place in our pharmacopeias, have now deservedly fallen into disrepute.

Before quitting this period of medical history, it will be necessary to say a few words respecting two other sects, which arose soon after the establishment of the methodic school: we mean the Eclectic and Pneumatic sects. The founder of the latter, Aristæus of Cilicia, flourished as a physician at Rome about the middle of the first century, and distinguished himself by his opposition to the tenets of Asclepiades, and his attachment to the Stoical system: he extended the theory of pre-existent germs; treated the doctrine of the pulse with dialectic subtlety, referring its varieties to the exhalation of the πνευμα from the heart and arteries; and cultivated several branches of pathology; but was more successful in his dietetical researches, particularly with respect to the influence of the atmosphere. His pupil Agathinus, endeavouring to reconcile his principles with those of the methodic and empiric sects, acquired the name of the Episynthetic or Eclectic, and thus established the Eclectic system, on which, however, he does not appear to have conferred much repute by his own labours. That merit was reserved for Archigenes and Aretæus, who, adopting the leading tenets of the Pneumatic theory, gave it a more scientific form, and enriched it by many valuable observations. The former attempted to reform the language of medicine, but without much effect; for even Galen has occasion to complain of the obscurity of his phraseology; he was, besides, too fond of subtleties: but many of his practical observations, which Galen has recorded, are excellent. The merits of Aretæus, as a skilful and attentive observer, and as an elegant describer of disease, are familiar to every one. To Cassius, the Jatrosophist, another Eclectic, we are indebted for many valuable pathological remarks concerning the diseases of association, and the sympathies of the nervous system.

During this period, surgery received considerable improvement; particularly from the labours of Heliodorus and of Antyllus. Of the former, who was an eminent surgeon at Rome, in the time of Trajan, Nicetas has preserved several practical observations, on injuries of the head and diseases of the bones, which evince no mean proficiency in his art. The latter is perhaps still more deserving of notice, as being the first who gives any account of the extraction of the cataract: he recommends this operation to be performed while the cataract is small, being of opinion, that, when enlarged, it cannot be extracted without bringing the humours of the eye along with it. (Rhaz. Continent. lib. ii. c. 3.) His directions concerning the preparation of plasters and ointments, and concerning the choice of veins in phlebotomy, are very minute. In dangerous cases of cynanche, he advises bronchotomy; and in *hernia humoralis* he operated by incision. Philagrius, who lived about the time of Valens, appears to have been the first who attempted to extract a stone from the bladder by the high operation. (Aët. Tetrab. iii. s. iii. c. 5.) The last quoted author has also transmitted to us an account of the surgical practice of one Leonides of Alexandria, whose observations on hernia, scrofula, and glandular swellings, on ulcers and warts of the genital organs, on hydrocele, and on inflammation of the scrotum, shew considerable discernment. In cancerous affections of the breast, he resorted to amputation, and the actual cautery; in *fistula*, his method of operation differed but little from that recommended by Pott.

The art of medicine was advancing thus rapidly in all its branches, when Galen appeared, a man of signal talents, who soon outstripped all his competitors in the profession, and divided with Hippocrates the admiration of the medical world. "Endowed with a genius sufficiently comprehensive to embrace all the sciences, and to cultivate them all with equal success," if we may borrow the language of Cabanis, "he, even in early infancy, gave proofs of uncommon capacity; and while pursuing his youthful studies, began to perceive the futility of the prevailing systems. Dissatisfied with what his masters taught him as incontrovertible truths, and as the immutable principles of the art, he read Hippocrates' works, and was struck, as it were, with a new light. In comparing them with Nature, his astonishment and admiration redoubled; and Hippocrates and Nature thenceforth became the only preceptors to whose instructions he would listen. He undertook the task of commenting upon the writings of the father of medicine; he presented his opinions in various lights, in which they had not hitherto been regarded; he repeated his observations, he extended them, and supported them with all the aids which philosophy and physics were capable of affording them, either by the simple comparison of facts, or by the collation of different theories, or, finally, by the combination of different methods of reasoning. In short, Galen revived the Hippocratic system of medicine, and communicated to it a lustre, which it did not possess in its primitive simplicity. But, at the same time, what it gained in his hands, must be allowed to have more the appearance of dress and ornament, than of real solid acquisition. The observations which had been collected, and the rules which had been laid down by Hippocrates, in assuming a more splendid and systematic form, lost much of their original purity; nature, whom the Coan physician had always followed with so much accuracy and caution, became obscured, and, as it were, stifled, by the foreign pomp of various sciences and dogmas; and the art of medicine, overcharged, as it already was, with subtle and superfluous rules, became entangled in a number of new and unnecessary difficulties." Q. c. p. 113.

Though possessed of more extensive erudition than either Hippocrates or Aretæus, Galen was decidedly their inferior as a pathological observer; not, however, so much from any defect of his mental powers, as from his attachment to false theory. It was on the pseudo-Hippocratic doctrines, particularly as developed in the book περι φυσιος ἀνθρωπου, that he founded his system. Although, therefore, he professed to follow Hippocrates, he did not always follow him in his genuine spirit. But all the departments of the art have been enriched by his labours: to anatomy and physiology, in particular, he made many useful additions by the information which he collected in his travels, and by his assiduous dissections of the inferior animals. For the history of his life and writings, and for an account of the ſyſtem which took its name from him, ſee GALEN and GALENICAL *Syſtem.*

Unfortunately the exertions of Galen, to preſerve the ſcience in the path of improvement, were not ſeconded by his immediate ſucceſſors. During a period of thirteen centuries, medicine remained nearly ſtationary, and, in ſome inſtances, aſſumed even a retrograde courſe. The beſt writers who appeared among the Greeks, ſuch as Oribaſius, Aëtius, Alexander Trallianus, Paulus Ægineta, Nicetas, &c. contented themſelves, in a great meaſure, with the merit of compilation; while among the eaſtern nations an unnatural union was attempted between medicine and the favourite ſtudies of magic and aſtrology. The Arabians, from their vicinity to Alexandria, from their intercourſe with the ſect of Neſtorians and with the Greek philoſophers, who had been compelled by the perſecution of Juſtinian to take refuge in the Mahometan ſtates, had acquired a taſte for literature and the ſciences. About the commencement of the ſeventh century, the works of ſeveral of the Greek philoſophers and phyſicians were tranſlated into Arabic, under the patronage of the caliphs; ſeveral of whom were zealous encouragers of learning. In the eighth century, the caliph Almanſur eſtabliſhed an academy and hoſpitals for the ſick at Bagdad, which ſoon became ſo great a reſort for men of letters from all parts of the world, that, as Leo Africanus aſſures us, it at one time contained ſix thouſand. His ſucceſſor, Harun-Arraſchid, patroniſed the medical ſchool of Jondiſabur, the teachers in which were chiefly Neſtorians; and both he and Almamun were unremitting in their exertions to procure tranſlations from the Greek, and the ſettlement of men of ſcience in their dominions. But it was in Spain that Arabian learning roſe to the higheſt pitch, and produced the moſt brilliant fruits. The univerſity of Cordova, which had been founded by Alhakem, became the moſt celebrated in the world, and maintained its repute for a long courſe of years. As early as the tenth century, Cordova could boaſt of the largeſt library in the Weſt; a library of 250,000 books, and of which the catalogue is ſaid to have filled forty-four volumes. In the twelfth century, there were no leſs than ſeventy public libraries in Spain: Cordova had produced 150 authors, Almeria 52, and Murcia 62. At Seville, at Toledo, and at Murcia, academies were alſo eſtabliſhed, which continued to flouriſh during the whole period of the dominion of the Arabians.

Notwithſtanding theſe numerous incitements to learning, notwithſtanding the multitude of authors which they produced, the labours of the Arabians in the field of ſcience were attended with but ſmall fruits. Worſhipping the authority of Ariſtotle and of Galen, they conſumed their time in commenting upon theſe writers, and neglected the path of individual obſervation and experiment. To anatomy they contributed nothing; the tenets of their religion forbad all attempts at diſſection; and the only thing they ventured upon was the inſpection of the ſkeleton. Their pathology, though disfigured by numberleſs extravagances, was enriched by the deſcription of ſome new diſeaſes, particularly of the ſmall-pox, which, according to the Arabian writers, broke out about the year 558, and of which the firſt account was given by Ahrun, the author of a work in the Syriac tongue, intitled "Pandects." Their practice, in as far as it deviated from the Grecian model, was miſerable quackery. The only improvement deſerving of notice was the introduction of lenitive medicines, in the place of draſtic purgatives, which had been too freely employed by the Greeks. A predilection for the wonderful led them to cultivate with great aſſiduity the arts of aſtrology and uroſcopy, and to deliver their judgments with all the airs of propheſying. National prejudices, and a falſe delicacy, prevented their making any progreſs in ſurgery; and Albucaſis had much reaſon to complain of the ignorance of his countrymen in that department of the ſcience. In the auxiliary arts of chemiſtry and pharmacy they were more ſucceſsful. The former had been cultivated by the later Alexandrians, principally with a view to the tranſmutation of metals; an art which ſeemed to poſſeſs great attractions in the eyes of the Arabians, and to which they accordingly applied themſelves with eagerneſs. Geber, who lived in the commencement of the eighth century, and who is ſaid to have been the firſt alchemiſt of his nation, ſeems to have been acquainted with various preparations of mercury, ſuch as corroſive ſublimate and red precipitate, with the nitric acid, aqua regia, &c. Pharmacy was an object of ſtill greater attention among them; and the Arabians have the credit of having ſet the firſt example of publiſhing regular diſpenſatories, or collections of authorized formulæ. The firſt pharmacopeia was the production of one Sabon-ebn-Sahel, head maſter of the academy of Jondiſabur, and appeared towards the end of the ninth century, under the title of "Krabadin." The ſhops of the Arabian apothecaries were placed under the immediate ſuperintendance of the magiſtracy, who took care that they ſhould be provided with genuine drugs, and that theſe ſhould be ſold at a reaſonable price. Many of the pharmaceutical terms ſtill employed are of Arabian origin, *e. g.* alcohol, naphtha, camphor, julep, ſyrup, &c. &c. For a more particular account of Arabian medicine, ſee Sprengel, G. d. A. Th. ii. ſ. 324—450 (2le Augs.): the modes of practice have been ſufficiently deſcribed by Freind.

If the Mahometans, generally ſpeaking, contributed little to the improvement of the ſcience, they have yet more claims on our gratitude than the Chriſtian profeſſors of the art during the ſame period. To the former we owe, in ſome meaſure, the preſervation and diffuſion of the writings of the Greek phyſicians: the latter did every thing in their power to degrade the profeſſion, and bring it back to its condition in the moſt barbarous times. The clergy, actuated by avaricious motives, ſeized upon the province of the phyſician, and the moſt ignorant prieſts and monks ventured upon the practice of medicine, without any proper ſtudy or preparation. At length the evil became too crying to be any longer endured; and the firſt Lateran council, held in 1123, forbad the regular clergy to viſit any longer the ſick. The prohibition was repeated, in other terms, by the council of Rheims, in 1131, and by the ſecond general Lateran council in 1139; and thoſe monks and canons, who applied themſelves to phyſic, "ordinis ſui propoſitum nullatenus attendentes, *pro deteſtanda pecunia ſanitatem pollicentes*," were threatened with ſevere penalties, and all biſhops, abbots, and priors, who connived at their miſconduct, were ordered to be ſuſpended from their eccleſiaſtical functions. "But the French prieſts and monks," ſays Cabanis, "bade defiance to theſe thundering anathemas; and it was not till three hundred years after, that common ſenſe and a regard to propriety and the public good, triumphed finally over their artifices. A ſpecial bull, procured by the cardinal d'Eſtonteville, which permitted phyſicians to marry, effected their complete ſeparation from the clergy; and, by this means alone, put a ſtop to a variety of ſhameful abuſes." To the honour of our own country, however, be it mentioned, that theſe abuſes do not appear to have prevailed to ſuch an extent among us; but that, on the contrary, England could reckon many ſcientific men among its clergy, even as early

as

as the seventh and eighth centuries, whose fame was so great as to procure them the chief literary appointments abroad. The learned society, which was formed at the court of Charlemagne, consisted chiefly of Britons, with the celebrated Alcuin at their head; and it would appear from the verses of the last-mentioned personage, that the members practised medicine:

> " Accurrunt medici mox Hippocratica tecta;
> Hic venas fundit, herbas hic miscet in olla,
> Ille coquit pultes, alter sed pocula præfert."
>
> Carmin. 228.

The Benedictine monks of Salerno, in the Neapolitan territory, after having exercised the art for several centuries, according to the taste of the age, and performed many miraculous cures with the relics of St. Matthew and other holy persons, betook themselves to the study of the Arabian and Grecian writers on physic, but especially of Galen, whom they esteemed the prince of physicians; and by their successful labours procured for their residence the title of *Civitas Medicinæ*. In the twelfth century, Salerno arrived at its highest fame; and was much frequented by the crusaders in their passage to and from the Holy Land. Among these, Robert, the son of William the Conqueror, had the honour of having the well-known " Regimen Sanitatis Salerni" dedicated to him. In the year 1140, the emperor Frederic II. conferred particular privileges on the school of Salerno, and regulated the course of studies, and the probations which physicians and surgeons should undergo before they were permitted to practise. Many of the ordinances shew great judgment. The Salernian school continued accordingly to flourish till the middle of the fourteenth century, when it appears to have begun to decline. " Fuisse Salerni," says Petrarch, " medicinæ fontem fama est; sed nihil est, quod non senio exarescat." Gariopontus, Nicolaus, Ægidius, Enos, and John of Milan, the author of the " Regimen Sanitatis," are the chief writers whom this school boasts.

Medicine was now generally taught in the universities of Europe, among which those of Montpellier, Paris, Bologna, Padua, Ferrara, Pavia, Milan, and Piacenza, were the most distinguished; but it was taught in a slavish spirit of adherence to the dogmas of Galen and Hippocrates, and, what was still worse, in combination with the scholastic philosophy. In 1271, the College of Surgeons at Paris was established by Pitard, a man who, according to Quesnay, was born for the advancement of his art; and surgery was henceforth cultivated with much success in France, as a distinct branch of the profession. Several writers on physic appeared in England; among whom Gilbert has the merit of having furnished the best description of the leprosy of the middle ages; but he trod in the footsteps of the Arabians, and gave into the scholastic style. The same remark applies to his successors, John of St. Giles, Richard of Windermere, Nicolas Farneham, John of Gaddesden, &c. It was in Italy that medical science was revived in the truest spirit. In the year 1315, Mondini de' Luzzi, professor at Bologna, astonished the whole world, to use Vicq d'Azyr's expression, by the public dissection of two human bodies. His example was followed in other universities; but the utility of the practice was in a great degree frustrated by the predilection for ancient opinions, which made the anatomists of the age less anxious to discover facts, than to reconcile the appearances which they observed with the dogmas of Galen and Avicenna. An absurd bull of pope Boniface VIII. forbidding the maceration and preparation of skeletons, also concurred to impede the progress of anatomy (Blumenbach, Hist. Med. Litterar. p. 99.): but from this time forward, the Italian professors maintained a high repute for anatomical science, and have ranked among the most zealous contributors to our knowledge of the human frame.

Though the crusades had conferred no direct benefits on science, but, on the contrary, had tended to prolong the reign of prejudice and folly, they had given a new impulse to the human mind, by the spirit of commerce which they excited. They were also the occasion of the rapid spreading of leprosy and some other diseases in the West, and of the consequent increase of institutions for the relief of the sick, after the example of the Oriental nations. Several orders of knighthood, as the Templars, the knights of St. John, of St. Lazarus, the *Hospitalarii Sancti Spiritus*, &c. were founded with this charitable view; the members devoting themselves to the cure of such pilgrims as were afflicted with disease.

In the fifteenth century several new diseases appear to have invaded mankind, or, at least, to have attacked them with a degree of violence that was before unknown; such as the hooping-cough, which was epidemic in France in the year 1414, and which, according to Mezeray, attacked all descriptions of persons, even the oldest men; the sweating sickness, that broke out first in 1486; the scurvy, of which some traces had been observed in earlier times, but which became much more common, perhaps in consequence of the greater frequency of sea voyages about this period; and, lastly, the venereal disease, the origin of which we shall investigate in a separate article. The rules of the ancients proving but little applicable to the treatment of these complaints, physicians began to doubt the infallibility of these guides, and to perceive the necessity of observing and judging for themselves. Nor was the influence of the revival of letters, and the great events by which it was followed, lost upon medicine. But, unfortunately, the taste for astrological studies continued to prevail, and to obstruct the progress of the art in all its branches. The auxiliary sciences received little improvement during this epoch.

The very general attention which was now paid to classical literature in the universities of Europe contributed to the restoration of the Hippocratic system of medicine. Among the Italians, Leonicenus and Manardus laboured to expose the errors of the Arabians, whom the latter justly designated as *ex commentario medicos;* among the Germans, Fuchs, Koch, Winter, and Hagenbut, made known to their countrymen the merits of the Greek physicians, by their translations and commentaries; and a similar service was performed in this country by Linacre and Caius. The Parisian school was still more zealous in the cause; Houlier, Duret, and Gorræus, elucidated the doctrines of Hippocrates with much success; and Foësius produced an edition of his works, which even at this day ranks as the most accurate and the most complete. Medical literature was still farther enriched by the magnificent collections of pathological observations, which the industry of Dodonæus, Schenckius, Forestus, and Platerus accomplished. A controversy respecting the mode of performing venesection in pleurisy, was begun in the early part of the sixteenth century by Brissot, a physician of Poitou, who observing the good effects of abstracting blood as near as possible from the seat of inflammation, had the courage to oppose the Arabian method, and to revive the Hippocratic practice. This important innovation, however, was opposed by the physicians of the time with great warmth, and continued the subject of violent dispute till the anatomical discoveries of Vesalius, Faloppia, and Amatus, turned the scale in Brissot's favour. The credulous and superstitious character of the age, however, was still opposed to any great improvement in the art of observing and curing disease:

disease: physicians were more anxious to collect what was wonderful than what was useful; their practice was directed chiefly by the theory of the elementary qualities, and was disfigured by many remnants of the barbarous ages. The best observer which the sixteenth century produced was Jodocus Lommius, the author of a classical work on the cure of continued fevers, and of "Three Books of Medical Observations."

Though the futility and absurdity of astrological science had been successfully exposed by Picus of Mirandola, Marlianus, and Paulus Florentinus, yet it continued to be pursued with unabated ardour, and to obtain many votaries, among men of otherwise great judgment and learning. Even those who evinced the greatest contempt for this nugatory art, could not divest themselves of a partiality for studies of an equally frivolous nature. Of this weakness we have a remarkable instance in Picus of Mirandola himself; who, after combating astrology, applied himself to the study of the Cabbalistic philosophy. The belief in the influence of demons, the efficacy of magic, and the powers of witchcraft, became very prevalent throughout Europe, and perhaps in no part of it to a greater degree than in England, which acquired the repute of being the country of witches. Even the illustrious Luther was so completely biassed by the prejudices of his age, that he ascribed the majority of diseases to the arts of the devil, and found great fault with physicians, when they attempted to account for them by natural causes. Alchemy had been hitherto cultivated only by the most illiterate men; but the introduction of theosophism and the cabbalistic art brought the study into great vogue, and it was thenceforth prosecuted with much eagerness by the monks and wandering scholastics (*scholastici vagantes*), under the patronage of kings and princes, who fondly hoped to augment their revenues by the products of this art. Though a law was passed by Henry IV., condemning as impostors the alchemists, who were then very numerous in England, yet they contrived to maintain their ground; and practised so adroitly on the weakness of his successor, Henry VI., that this monarch, finding his treasures exhausted by the unfortunate wars in which he had engaged, granted to certain transmuters of metals the privilege of making gold, and preparing the elixir of life. (Henry's Hist. of G. B. b. v. ch. iv. § 7.) The labours of Basilius Valentinus, the reputed author of the "Currus Antimonii Triumphalis," and of Isaac le Hollandois, were rather more usefully directed; but it was reserved for Paracelsus to appropriate to himself all the knowledge which his predecessors had attained in this branch of learning, and to apply it with success to medicine.

It has been too much the fashion to ridicule this singular man, and to overlook his merits as one of the great reformers of our art; though it must be acknowledged, that the extravagance of his pretensions, his insolent behaviour, and his dissolute manners, afford strong grounds for much of the contempt with which he has been visited. The early education of Paracelsus, or, as he called himself, Philippus Aureolus Theophrastus Paracelsus Bombast von Hohenheim, would appear to have been greatly neglected: and, notwithstanding his asseveration, that he had been at German, French, and Italian universities, it is sufficiently evident from his writings, that he could never have enjoyed the benefit of proper classical instruction. From his father, who is said to have been a physician, he obtained a smattering of medicine, astrology, and alchemy: he afterwards served as surgeon in several wars, and visited most of the countries of Europe, seeking information not only from physicians and other men of learning, but from old women, from the gipsies, and from conjurers. From these he boasts of having learned the preparation of several valuable remedies: from his intercourse with the miners, he became acquainted with various processes for extracting metals. Returning to Germany, he soon acquired great repute by his cures, and was believed to have discovered the elixir of life. In the year 1526, his increasing fame procured him the appointment of professor of medicine and surgery in the university of Basle; where he commenced a course of lectures on the theory and practice of physic, in the German language, and succeeded in attracting a considerable audience, but chiefly from among the dregs of the people, who, seduced by his vauntings, were eager to obtain the knowledge of his secrets. He began by burning the works of Galen and of Avicenna, in his auditory, assuring his hearers "that his shoe-latchets possessed more knowledge than Galen and Avicenna; that all the academies of the world had not so much experience as his beard; and that the hair of the back of his neck was more learned than the whole tribe of authors." The lectures, however, which he delivered, consisted of little else than the recommendation of a number of empirical remedies, of the infallibility of which he spoke with much assurance. But his disciples soon became disgusted with him, on account of the drunken irregular life which he led; and though he still continued to perform many wonderful cures, his fame as a practitioner began to decline, and a dispute with the magistracy compelled him suddenly to quit Basle, and to take refuge at Alsace. He, however, did not settle there, but continued to lead a wandering life through different parts of Germany and Switzerland, till the year 1541, when he died at Salzburgh, in the hospital of St. Stephen.

The obscure and barbarous style in which the writings of Paracelsus are composed, has rendered it a matter of great difficulty to give a clear account of his speculative opinions. Even the indefatigable Hensler (Geschichte der Lustseuche, s. 120.) complains, that it was with him the business of several months to unravel the confusion of his system. Certain, however, it is, that there never was a more glaring example of the error to which chemists have been ever prone—that of carrying into other sciences what Bacon appropriately calls "the smoke and tarnish of the furnace." The elements of the living system he fancied to be the same as those of his laboratory; and sulphur, salt, and quicksilver, were, according to Paracelsus, the constituents of all organized bodies. They were combined by chemical operations, and their relations were governed by the *Archeus*, or demon, who performed the part of alchemist in the stomach, who separated the poisonous from the nutritive part of the food, and who communicated the tincture by which the food became capable of assimilation. This governor in the stomach, this *spiritus vitæ*, this *astral body* of man, was the immediate cause of all diseases, and the chief agent in their cure; yet each member of the body was supposed to have its peculiar stomach, by which the work of secretion was effected. Diseases were produced by certain influences, of which Paracelsus reckoned five, *viz. ens astrale, ens veneni, ens naturale, ens spirituale,* and *ens deale.* When the archeus was sick, putrescence was occasioned, and that either *localiter* or *emunctorialiter. Tartarus,* or a certain morbific matter, was the cause of all disorders, exhibiting a viscidity of the fluids, rigidity of the solids, or a concretion of earthy matter, and was believed to be secreted when archeus operated in an irregular or too potent a manner, and digestion was too fully performed. Such speculations, considered abstractedly, are no doubt very absurd; but when divested of the cabbalistical jargon in which they have been enveloped, they will be found to contain a certain portion of truth. Of so great value have

have the views of Paracelsus respecting the functions and diseases of the digestive organs latterly appeared, that they have been revived with little alteration, though clothed in a new dress, by a writer at the commencement of the nineteenth century, in a treatise "On Disorders of the Stomach."

The best and most original of Paracelsus' works is his treatise, in three books, on the venereal disease, entitled "Von den Imposturen in den Franzosen;" in which he has given a minute description of the various forms of syphilis, and shewn in what manner other disorders were liable to be modified by its presence; and in which he has successfully exposed the errors, or, as he terms them, "impostures," of the then prevailing practice. Instead of the inert fumigations, quintessences, and diet drinks, which were in vogue, he recommended mercury as the only remedy on which dependence could be placed, and exhibited it both internally, and by the way of friction. Medicine, in general, was indebted to him for the free introduction of this and other mineral remedies, and of opium, and for pointing out the necessity of attending to chemical actions in pharmaceutical operations. To complex prescriptions he was no friend, and he ridiculed with considerable effect the absurdity of imagining, that 40 or 50 simples in a compound would all retain and exert their separate virtues. The treatment of wounds and ulcers received great improvement at his hands, and his observations on the *balsam* (coagulable lymph), by which he supposed nature to effect their cure, display no small degree of discernment. His confidence in his *arcana* led him to condemn the use of cauterizing instruments, and even to reject the employment of sutures.

The *anatomy of Mundini* was servilely followed as a text-book in all the universities of Europe till towards the middle of the sixteenth century, when the discoveries of Achillini, Berengar of Carpi, Serveto, Sylvius, and Eustachius, but, above all, of Faloppia and Vesalius, threw a new light on the science, and established it on an unalterable basis. Galen was no longer appealed to on doubtful points; on the contrary, anatomists seemed to vie with each other in exposing his errors, and in multiplying the proofs of their observations, by repeated dissections. The structure of the organ of hearing, and other parts of the osseous system, which had escaped the notice of the ancients, was now fully investigated; the arrangement and formation of the muscles were examined, and the mistake of supposing them to consist of an union of tendinous and nervous fibres was satisfactorily confuted; the nerves were traced from their origins, and the base of the brain was minutely described. But it was in respect to the vascular system, that the most brilliant and fruitful discoveries took place. Berengar, who had paid great attention to the structure of the heart, conjectured the right use of the semilunar valves. So early as 1547, Cannani and Amatus had observed the valve at the termination of the vena azygos; but they had not turned the discovery to account; and it was reserved for Fabricius of Aquapendente to prove the presence of valves throughout the whole course of the veins. Five years afterwards, the circulation of the blood through the lungs was imperfectly described by Servetus, who had availed himself of the researches of Berengar and Vesalius. In the year 1571, Cæsalpini had the merit of stating it more clearly, and even of suggesting the first hint of the greater circulation (De Plantis, lib. i. c. 2.); but the full honour of the latter discovery, at least of its complete demonstration, must be ascribed to our countryman, Harvey. See CIRCULATION.

It is sufficiently apparent, even from the above imperfect account, that nothing but a succession of fortunate events could ever have brought about this great improvement in physiological science. The discovery of the circulation of the blood was one of those occurrences, which, to use the language of Bacon, "are more the birth of time than of genius;" and, though the merit of it could only belong to a man of transcendent talents, yet we rather detract from, than add to the glory of Harvey, by supposing him to have hit upon it by chance, unguided by the light which he had received from the instructions of his predecessors and contemporaries. We may also observe, that the beneficial consequences of the discovery in question have been greatly overrated, at least as far as practical medicine is concerned; and, in this point of view, we cannot help subscribing most fully to the opinions of a writer, whom we have had frequent occasion to quote. "The new light," Mr. Cabanis remarks, "which was thrown upon the animal economy by this important discovery, served only, in a manner, to redouble the rage of systems. Nothing else was thought of, but to cause the blood to circulate more freely, to destroy its viscosity, to draw off from the body that which was supposed to be corrupted, to purify it, correct it, and renew it, and to preserve the blood-vessels in a relaxed and pervious state. Hence those torrents of aqueous and diluent drinks, with which Bontekoe and his adherents deluged their patients. Hence that sanguinary fury, which the partisans of Botalli thought themselves entitled to exercise in their treatment of all sorts of diseases; a fury which, though so often damped, in some measure, by systematic murders, has ceased only for intervals, and still from time to time re-appears in the schools. Hence, too, that wretched mania of the transfusion of blood, of which the practice almost always deprived those who had the temerity to subject themselves to so dangerous an operation, of their reason, or their lives.

"Thus, one of the most beautiful discoveries of modern medicine, far from elucidating the practice of the art, as there was every reason to expect, only had the effect of misleading weak imaginations, dazzled by its splendour; and it may still be doubted, whether its application to the knowledge and cure of internal diseases has been of any real use. In surgical cases, even where its assistance is generally regarded as indispensable, might not observation almost always supply its place? And must we not limit its importance to the elucidation of a point in anatomy and physiology, very curious, no doubt, in itself; but which, if it did not indirectly affect many other interesting questions relative to the animal economy, would probably have contributed very little to our knowledge of its true laws?" Loc. cit. p. 166—8.

A system that is founded on mysticism, and clothed in obscurity of language, is sure to find numerous votaries. Accordingly, the doctrines of Paracelsus, notwithstanding the opposition of Erastus, Dessenius, Libavius, and others, continued to attract adherents in all the countries of Europe, but particularly in Germany. They were eagerly embraced by the fraternity of Rosicrucians, among whom our countryman, Fludd, made himself conspicuous by his uncommon proficiency in cabbalistical and astrological learning. But of all the followers of Paracelsus, Van Helmont was the only one who could be said to tread successfully in the footsteps of his master; attacking vigorously, on the one hand, the Galenical system; and labouring, on the other hand, with unremitting zeal in the prosecution of chemical research. Though misled in his speculations by a strong bias to theosophism, he must be allowed to have shewn himself, on many occasions, a skilful observer of nature: he was the first who pointed out distinctly the influence which the epigastric organs exert upon the other parts of the system,

ſyſtem, in health as well as diſeaſe; he determined the nature and cauſe of inflammation more accurately than any of his predeceſſors had done; he gave the firſt ſatisfactory explanation of the origin of calculi; he expoſed the abſurdity of the prevailing theory of putrefaction of the blood; and he placed in a ſtrong point of view the pernicious conſequences and the dangers of exceſſive blood-letting. Chemiſtry owes to him the diſcovery of carbonic acid and hydrogen gas, and the firſt inveſtigation of their properties. In his practice he made great uſe of calomel, of antimony, wine, and opium; and it is ſomewhat remarkable, that with regard to the virtues of the laſt mentioned remedy, he in ſome meaſure anticipated the Brunonian doctrine; for he maintained that opium was not to be conſidered as a *refrigerant* medicine, but as a *tonic* and *anodyne*. The utility of Van Helmont's labours, however, was leſſened by his attachment to the Paracelſian phraſeology; and, as his works were not publiſhed till a conſiderable time after his death, when other ſyſtems had come into vogue, his doctrines had few adherents, at leaſt in their original ſtate.

We have already had occaſion to obſerve the influence which the prevailing ſyſtems of philoſophy have exerted on medicine. In no period of medical hiſtory was this influence greater than in that of which we are now about to treat: in no period has it been productive of more marked effects. From the revival of letters to the commencement of the ſeventeenth century, Ariſtotle had continued to be the great authority of the ſchools; dialectic ſtudies were conſidered as the beſt preparative for all the other branches of learning; and natural philoſophy, in particular, was confined within very narrow limits by its union with the ſcholaſtic diſcipline. Some philoſophers, it is true, had ſtumbled, as it were, on the proper road of its inveſtigation, and, freeing themſelves from the ſlaviſh admiration of received opinions, had proſecuted, with conſiderable ſucceſs, their inquiries in ſeveral departments of phyſical reſearch: but the ſlow and uncertain advances which they made, prove, that their march was wavering and their footing inſecure; that they had ſoon deviated from the path, and had never diſcovered its whole extent. It was reſerved for the genius of Bacon to point out the various ſources of error, by which they had been miſled; to demonſtrate the true end and uſe of all ſcientific inquiry; to ſhew the only method by which it could be ſucceſsfully purſued; and to deliver the code by which the ſtudy of nature muſt be thenceforth conducted. Embracing in his comprehenſive mind the whole circle of human knowledge, he ſaw that in medicine much remained to be accompliſhed; and recalling the attention of phyſicians to the proper objects of inveſtigation, he inculcated the neceſſity of a ſtrict adherence to the path of obſervation and experiment, as the only way by which their art could be improved. By this recommendation, he juſtly remarks, that he was only enforcing the example of Hippocrates, which had been too long neglected: but his views were more correct and enlarged than thoſe of the father of phyſic, and more fully adapted to the exiſting condition of the ſcience, or rather, to ſpeak more accurately, to its future progreſs; for it has been only in very late times, that ſome of the more important *deſiderata*, which Bacon indicated, have been completely realiſed; as, for inſtance, his directions concerning the proſecution of morbid anatomy, and his ſuggeſtion of "an imitation by art of natural bathes and medicinable fountaines &c." Medical ſcience, however, has profited much leſs than it ought to have done by the labours of this truly great man; his writings were for a long time neglected; and, even at this day, though we talk of the reform in the method of inveſtigation which Bacon introduced, the undigeſted knowledge and crude ſpeculations of too many of our phyſicians demonſtrate, that they neither obſerve his model, nor fully comprehend his precepts. Till the preſent age, Baglivi appears to have been the only writer who knew how to appretiate the importance of the "Novum Organum," as a guide in medical inquiries; but his unfortunate predilection for the chemico-mechanical theory, led him too often to forget the maxims to which he had given his cordial aſſent, and to commit thoſe very errors which in others he had ſeverely reprehended.

The efforts of Bacon to overthrow the Ariſtotelian philoſophy were powerfully ſeconded by Deſcartes. As the opinions of the latter found a much readier reception among the learned, eſpecially on the continent, than thoſe of our illuſtrious countryman, they accordingly had a more immediate operation, and impreſs their character more diſtinctly on the ſpeculations of the age; but their tendency was in many reſpects injurious to the intereſts of medical ſcience. Adopting ſome of the moſt objectionable parts of Van Helmont's ſyſtem, particularly the doctrine of fermentation, and combining them with his own hypotheſis of vortical motion, Deſcartes attempts to explain all the chief functions of the living body on chemico-mechanical principles. Thus, the circulation of the blood and animal heat were produced by the ebullition or fermentation that took place in the heart; digeſtion was likewiſe performed by a ſpecies of fermentation; and the ſenſation of hunger proceeded from the acid which was evolved during the proceſs. To explain the nature of ſecretion, Deſcartes had recourſe to the corpuſcular philoſophy; comparing the ſecreting organs to ſieves, which allowed only the more minute and homogeneous particles to paſs through, while the coarſer and heterogeneous bodies were rejected:—the round particles were ſuppoſed by him to enter into cylindrical tubes; pyramidal particles penetrated by triangular pores, and cubical particles by ſquare pores; and in this way each ſecretion remained diſtinct, at leaſt in the healthy ſtate. Theſe ideas were eagerly embraced by the Dutch phyſicians of the time, and may be conſidered as forming the groundwork of the chemical and mechanical ſyſtems, which divided the medical world at the end of the ſeventeenth century, notwithſtanding the claims to originality which ſeveral of their followers have put in.

If the importance of the chemical ſyſtem of medicine were to be eſtimated by the portion of good which it has effected, its hiſtory might be brought within a very ſmall compaſs; but if it ſhould be viewed as one of the chief impediments to the free progreſs of the art, which ſo many circumſtances had conſpired to favour; if it ſhould be conſidered in relation to the miſchievous bent which it gave to medical ſpeculations, and, above all, in relation to the fatal errors of practice which it countenanced; few ſyſtems would appear entitled to more ſerious notice. Its firſt and great ſupporter was Francis de le Böe Sylvius, a man of no mean talents, a ſkilful anatomiſt, and the firſt inſtitutor of clinical lectures in hoſpitals. Though he perceived the full value of experience in medicine, and ſtrenuouſly inculcated the neceſſity of ſubjecting all theories to its teſt; yet he allowed himſelf to be dazzled by the glare of opinions, which not only were not confirmed by experience, but which were, for the moſt part, in direct oppoſition to its leſſons. Fancying that all the operations of life might be explained by a few chemical principles, he could diſcern nothing but fermentations, ebullitions, and combuſtions, in the different organs of the body, except, indeed, that he ſuppoſed the animal ſpirits to be produced by a diſtillation in the brain; diſeaſes were referred by him to an exceſs of either acid or

 alkali

alkali in the fluids, to which he gave the name of *acrimony*, and the consequent inspissation or attenuation of the blood and lymph; and they were to be cured only by neutralizing the morbific cause. Thus, he sought to correct the acrimony of the bile by opium and other narcotic remedies; in intermittent fevers, which he believed to proceed from the acid acrimony of the pancreatic juice, he administered the *sal succini volatile* and opium; and in malignant fevers, which he ascribed to an alkaline acrimony and attenuation of the humours, he gave acids, ethers, opium, absorbent earths, and cordials,—paying no regard to the different stages of the disorder, or the character of the prevailing epidemic; but solely intent on fulfilling the indications of his mistaken theory. In this way, the practice of medicine may be said to have commenced a retrograde march, from which it long suffered, and from the injurious consequences of which it has scarcely yet entirely recovered.

After a slight opposition, the doctrines of Sylvius were almost universally adopted. In England, indeed, they experienced some modification, without becoming more rational, as we have elsewhere shewn (see HUMORAL *pathology*); and in Italy, where mathematical studies had acquired the ascendency, though they were received by many, yet they never obtained that exclusive sway which they enjoyed in other countries. The professors of Paris and Montpellier, refining upon the Helmontian and Cartesian hypothesis, divided the fermentations of the fluids into several distinct species; attempted to account for their production by the admixture of the animal spirits from the brain; and formed a classification of fevers into *fievres chyleuses*, and *fievres sanguines*. Attempts were even made, and with apparent success, by Viridet, Vieussens, and others, to demonstrate, by experiment, the presence of alkali in the bile, and of acid in the blood, in the pancreatic and gastric juices. But it was in Holland and Germany that this system had its most bigotted votaries, and was pushed to the most absurd and pernicious extreme. Thus one physician conceived, that acidity was the sole and universal cause of disease; another affirmed, that gout originated from the effervescence of the synovia of the joints with the vitriolated blood, and recommended alcohol for its cure; while a third deduced all disorders whatever from inspissation of the fluids, and expatiated on the sovereign efficacy of diluent drinks, especially of tea. "Tea," says Bontekoe, who is loudest in his praises of this panacea, and who, as Blumenbach remarks, deserved to have been pensioned by the East India Company for his services,—"tea is the best, nay the only remedy for correcting viscidity of the blood, the source of all diseases, and for dissipating the acid of the stomach; as it contains a fine oleaginous volatile salt, and certain subtle spirits, which are analogous in their nature to the animal spirits. Tea fortifies the memory and all the intellectual faculties: it will therefore furnish the most effectual means of improving physical education. Against fever there is no better remedy than 40 or 50 cups of tea, swallowed immediately after one another: the slime of the pancreas is in this way carried off." (Abhandlung vom Menschlichen Leben, Budissen, 1685.) A physician of Minden, named Van der Becke, attempted an union between the chemical hypothesis and the peripatetic philosophy,—taking water, or alkali, for the *matter*, and fire, or acid, for the *form*, of all organized bodies; and was followed by one Van Rustingh, who derived all diseases from a deficiency or a redundancy of fire or water; maintaining, for example, that, where the water predominated, the fluids became viscid, and intermittent fevers and arthritic complaints arose: these were to be cured by volatile salts, which contain many fiery particles. Condemning the employment of venesection *in t to*, this author did not scruple to adopt the same *fiery* treatment in various inflammatory distempers: so completely had false theory obscured his mind; and to such a deplorable state was medical practice reduced, in the hands of these chemical dreamers!

Some few, however, had the sagacity to perceive the inadequacy of such speculations to illustrate the phenomena of life, and ventured to call in question the propriety of applying them to the treatment of disease. Boyle, in his "Sceptical Chemist," and other essays, had refuted the hypothesis of acid and alkali; and Le Mort, pursuing his ideas, attacked the doctrine of fermentation, and substituted a theory of his own, which was more immediately grounded on the corpuscular philosophy. Bohn, a professor of medicine at Leipsic, brought forward a number of arguments to prove that digestion was not effected by any fermentative process; that, in the healthy state at least, there was no acid fermentation in the stomach; and that the presence of acidity, instead of assisting, rather impaired the functions of that organ. He shewed, by experiment, that the bile did not effervesce on the addition of acids; and he controverted the doctrine of a nervous fluid, as inconsistent with the structure and properties of the nerves. Pechlin and Brunner proved, that the hypothesis of the acid nature of the pancreatic juice was utterly unfounded; that this fluid did not effervesce with the bile; and that it was not even necessary for digestion. In this manner several physiological facts became ascertained; and this is the only way in which the chemical theory can be said to have done any thing for the progress of science.

The practical errors of the chemists were ably exposed by Sydenham, who, having applied himself late in life to the study of his profession, was never so strongly imbued with the prejudices of the schools, but that he could easily shake them off when they would not bend to his experience; and who, living on terms of intimacy with Boyle and Locke, brought into medicine many of those sound and enlightened views, which had guided their researches in other departments of learning. Adopting the suggestion of Bacon, Sydenham returned to the Hippocratic method of collecting histories of disease, and shewed the necessity of coming to its observation with an unbiassed mind; of attending more carefully to its distinguishing characters; and of marking all the circumstances by which it was liable to be modified. He saw that sufficient diligence and discrimination had not been used in these particulars; that observers either had confined their attention to uncommon cases, or, misguided by false hypothesis, had given imperfect and erroneous views of the disorders which they attempted to describe. It was only, he maintained, by discarding all hypothetical reasonings, and by investigating minutely the succession of symptoms, that we should ever be able to arrive at the knowledge of the causes, and the curative indications of disease. Accordingly, though he forgot his own precept, and indulged much in fanciful speculation, Sydenham laboured assiduously to improve the practice of medicine, and has justly acquired the title of its reformer. The descriptions which he furnished of the various epidemics of his time have served as models to succeeding writers, and in point of simplicity and accuracy have scarcely ever been surpassed: his "Treatise on the Gout" is still consulted as one of the best accounts of that disease. Sydenham is also to be regarded as the reviver of the antiphlogistic method; for he was the first who pointed out all the dangers of the stimulant plan which the chemists pursued in the early stages of acute disorders, and which, in many instances, but especially in small-pox, had been attended with the most fatal consequences. The practical doctrines of Sydenham, indeed, were adopted by few of his

his contemporaries; and at the commencement of the following century a large proportion of the English physicians continued to advocate the Sylvian hypothesis, or some of its modifications.

In proportion as true chemical science advanced, the partiality for chemical explications of the functions of the living system abated; and physicians seem to have discovered, for the first time, that the theory of the humours, even with all the improvements which it derived from the corpuscular philosophy, threw no light whatever on the actions of the solids. A new hypothesis, therefore, was projected; and as men, in avoiding one error, are apt to run into the opposite extreme, physiologists now attempted to explain all the phenomena of life according to the mere mechanical powers of the organs, and to reduce the laws of the animal economy to the rigid calculations of geometry. They imagined, that they could illustrate every operation of the human body, by comparing it to a system of ropes, levers, and pullies, united with a number of rigid tubes of different lengths and diameters, containing fluids, which, from variations in the impelling causes, moved with different degrees of velocity. When the fibres of this machine were not sufficiently flexible; when the pullies and joints of the levers were not kept in sufficient repair; or when the apertures of the pipes were not sufficiently free; the movements were necessarily suspended, or less perfectly performed, and they were only to be brought into proper regulation, according to the practitioners who adopted this fanciful theory, by removing the above described impediments. The composition of the fluids was supposed to be the result of their motion in the tubes; and in these nothing was attended to but the forces of gravity and cohesion; as in calculating the action of a pump, or other hydraulic engine. "If the chemical school," to use the words of Sprengel, "had degraded the physician to the rank of a brewer or distiller, the disciples of the iatro-mechanical school, on the other hand, were glad to be esteemed as hydraulical engineers; and several of them, in fact, served in the double capacity of engineers and professors of medicine." One of them, Dionis, a professor of surgery at the Jardin du Roi, went so far as to compare the circulatory system to the water-works at Marly, by which the water of the Seine is raised to considerable height, and from thence made to fall again upon the great wheel.

Among the causes which conduced to the establishment of this sect, the discovery of the circulation of the blood is the most prominent. When it was found that the blood flowed in a regular manner, through certain conduits, from the heart, and returned to that organ, by other vessels, from the extremities, physicians set about calculating the mechanical force which they supposed necessary for enabling the heart and arteries to produce this effect; and, elated with their apparent success, were led by degrees to transfer their calculations to the other functions of the body. Geometry had become the prevailing study of the learned; and societies for the promotion of experimental philosophy were established in the different countries of Europe, among which the Florentine academy del Cimento took, in some measure, the lead. It was in Italy that mathematics had been most assiduously cultivated; and it was there that the first attempt was made to introduce them into medicine. In the year 1614, Sanctorius published his "Medicina Statica," in which he endeavoured to shew the great influence which the insensible perspiration has upon health, and to calculate with precision all the variations in its quantity, in the different conditions of the body. According to his theory, diseases originated from the noxious particles of the food being retained in the system, in consequence of the stoppage of the transpiration; and till the latter function was restored to the proper standard, no cure could well take place. Sanctorius distinguished the different alimentary matters according to their specific gravities, and according as they appeared more or less fitted to pass off in the way of insensible perspiration; he even ventured to apply his maxims to the passions of the mind; shewing how joy and equanimity favoured the excretions, while sorrow and fear impeded them; how fevers and melancholy arose from the obstructed perspirable matter, where grief was long continued; and how they were to be removed by restoring the suspended exhalation. Among the "Aphorisms" of Sanctorius, there are many sound observations; and medical science is under considerable obligations to him for having directed the attention of physiologists to the functions of the skin, which, till then, had been in a great measure overlooked; but his views, like those of most theorists, were far too partial; and there can be little doubt that, in one respect, they had a most injurious influence, *viz.* by encouraging physicians in the universal employment of sudorifics, to which they were already too prone; and no one will now subscribe to the judgment of Boerhaave, who says of Sanctorius and his work, "Nullus medicorum, qui ante eum scripserunt, cardinem rei ita adtigit—nec ullus liber in re medica ad eam perfectionem scriptus est."

Such were the advances towards the formation of that system on which the talents of Borelli, Baglivi, and Bernouilli, in Italy, and of Pitcairne, Keil, Wintringham, and Mead in England, afterwards shed so much lustre. Among the French it found comparatively few supporters, though a certain Peter Chirac was captivated with Borelli's ideas to that degree, that he bequeathed 30,000 livres towards the establishment of two professorships at Montpellier; the one for comparative anatomy, and the other for the iatro-mechanical theory: but in Holland and Germany it soon made its way, and was taught at all the principal universities. That the labours of Borelli and his successors were often confirmed by observation, and have served to illustrate those movements of the living body which are clearly referrible to mechanical laws, such as the compound actions of the muscles, the functions of the eye, &c. will not be denied: but when mathematical reasonings were applied to phenomena, which furnished no fixed data for calculation, and which were, in fact, to be investigated by very different methods, no useful result could be expected. Accordingly it happened, that almost every calculator came to a different conclusion from those who had preceded him in the inquiry. Borelli, comparing the mass of the heart with that of the temporal and masseter muscles, concluded that that organ was capable of supporting a weight of 3000 pounds, and that its absolute power was therefore equal to 3000; but, as it had to overcome a resistance in the smaller arteries at least sixty times greater, its relative power must be estimated at 180,000 pounds. Keil, on the other hand, applying the Newtonian doctrine of gravitation to the motion of the blood, maintained that the power of the heart was only from five to eight ounces: but his calculations were controverted by Jurin, who made it fifteen pounds three ounces. Again, with regard to digestion, which these mechanists conceived to be only a species of trituration, Borelli instituted a comparison between the human stomach and the stomachs of different species of birds, estimating, for example, the power of that organ in the turkey-cock at 1350; Hecquet calculated the power of the coats of the human stomach and abdominal muscles at 261,000; while Astruc asserted that it amounted to only four pounds three ounces. Secretion, in like manner, was supposed to depend on the various

diameter

diameter of the secreting vessels, on their different convolutions, and on the angles at which they branched off from the arteries. But in order to ensure success in the most simple of these inquiries, "it would be necessary," as D'Alembert has shewn, "to know exactly to what degree the vessels are capable of dilatation; in what manner, and according to what law, they are dilated; to be perfectly acquainted with their figure, with their various elasticity, with their different anastomoses, with the number, the strength, and the position of their valves; with the heat of the blood, and the degree of tenacity which it possesses; and with the moving powers which impel it. Even supposing each of these particulars to be accurately known, still the great number of elements, which would enter into such a theorem, would probably render all our calculations fruitless." Elemens de Philosophie, Amst. 1764, p. 268. It is almost needless to add, that not one of these circumstances was ever properly ascertained: the laborious calculations of the mechanical physicians were therefore, for the most part, wholly nugatory.

In some respects, however, they must be allowed to have had a beneficial tendency. By accustoming the mind to the strictness of mathematical methods; by fixing the attention of physiologists on points of the animal economy that had been previously but little investigated; and by inducing them to seek occasionally for experimental proofs of their theories; they led to discoveries which probably would otherwise have long remained unmade. From the time of Harvey to the middle of the last century, in fact, anatomy continued to make great progress; the errors which had obscured its study were gradually dissipated; and the more important functions of the organic frame were explained with all the rigour of demonstration. A summary view of the principal discoveries of this epoch will shew the importance, and also, in some degree, the share which the followers of the mechanical sect had in them.

The heart had been regarded as a parenchymatous vessel by the ancients, with the exception of the author of the pseudo-Hippocratic treatise, περὶ καρδίης, who calls it a *strong muscle*. In the year 1663, Stenonis ascertained the muscularity of its structure; and three years afterwards the work of Lower appeared, in which all the circumstances of its position and organization were more fully demonstrated. Wepfer, a physician of Suabia, instituted various experiments with cicuta and other poisons, which proved that the blood was only the exciting, and not the proximate cause, of the motion of the heart; and that this motion depended solely on the organic powers of that organ. Lange, a professor at Leipzig, gave, in the year 1680, an account of some experiments with injections, by which several important facts connected with the circulation were brought to light. He succeeded, for example, in injecting the cells of the lungs from the pulmonary artery, and the placenta from the arteries of the uterus. In 1683, a Dublin professor of the name of Molyneux demonstrated, by aid of the microscope, the circulation in the amphibia: but it was chiefly through the indefatigable exertions of Leeuwenhoek, that this new instrument of anatomical observation was brought to perfection, and that full ocular proof was afforded of the Harveian discovery. By successive improvements on his magnifiers, he was at last enabled to perceive distinctly the passage of the blood from the smallest arteries into the veins, and the continuity of these two sets of vessels; and to observe the figures of the globules of the blood. The art of injection, which was carried to a great degree of nicety by Ruysch, served also to throw new light on the vascular system. Vieussens gave a minute description of the *vena cava*, and pointed out the *fossa ovalis* and the ring by which it is encompassed: and, in the year 1700, he discovered the serous vessels of the *uvea*. Gastaldy, having divided the intercostal and eighth pair of nerves, above the heart, found that it still continued to contract; whence he justly inferred, that its action did not depend on the nervous influence. The experimental labours of Hales and Wintringham served to determine several questions relating to the motion of the blood, the connection of the veins and arteries, and their relative strength; but their calculations concerning the force of the heart and the velocity of the blood were all founded on the arbitrary principles of the mechanical system. Weitbrecht and De Gorter proved the independent action of the arteries; and, lastly, Senac and Haller put an end to all controversy on the subject by their masterly descriptions of the heart, and the complete analysis of its functions.

Previously to the publication of Harvey's work on the circulation, Faber, a physician at Rome, had ascertained by experiment, that no air passed into the heart by the lungs; but very erroneous ideas concerning the functions of the latter organs continued to prevail, till Malpighi ascertained their real structure, and Mayow proved the necessity of oxygen gas for the due performance of respiration. Lower, adopting the doctrines of Mayow, was led to the conclusion, that the red colour of the blood depended on the presence of the "*nitro-aëricus* particles" of the atmosphere. Borelli, however, had the merit of giving the first complete explanation of the mechanism of respiration; shewing how the ribs and sternum are elevated by the action of the intercostal muscles, and how the cavity of the thorax is in that manner enlarged, while the lungs remained in a great measure passive; and how the air, which is inspired, is never entirely expired, though it becomes more rarefied. He rejected the hypothesis of a vital heat in the heart, and referred the exhalation from the lungs to an excretion from the bronchial glands. These opinions were adopted and extended by Pitcairn, Strœm, and Lister. In the year 1715, Muschenbroek published his dissertation "De Aëre in Humoribus," in which he refuted several erroneous notions that had been entertained on the subject of respiration, particularly the doctrine of the admixture of the air with the blood, and of the presence of air between the pleura and the lungs. A controversy that arose between Hamberger, a disciple of the mechanical school, and Haller, had the effect of determining some disputed points relative to the action of the intercostal muscles and the state of the lungs in respiration; and the experiments, which Hales instituted with the air-pump, shewed the effects of the deprivation of air on the sensible properties of the blood.

On the 23d of July, 1622, Caspar Aselli, while dissecting a live dog, at the request of some friends, in order to demonstrate the recurrent nerves, observed a number of small white threads crossing the mesentery. At first he conceived they were nerves; but happening to cut into one of them, he remarked a small portion of a milky fluid flowing from the opening. Full of joy at this unexpected discovery, he cried out to the bystanders εὕρηκα, and resolved to lose no time in repeating the experiment. Finding, accordingly, that these vessels were observable in living animals, only after a full meal, he concluded that they were the true *vasa chylifera*; which was further proved by their origin in the villous coat of the intestines, and by the valves with which they were furnished: but he erroneously supposed them to unite in the pancreas, and from that to pass into the liver. The observation of Aselli was soon afterwards confirmed in the human body by Peiresc, Vesling, and others;

others; but the same false notions of their termination continued to prevail, till Pecquet, in the year 1647, struck with the appearance of a milky fluid in the vena cava of a dog, was led to the discovery of the thoracic duct. This great discovery, like that of the circulation of the blood, was disputed with much warmth; and it is a blot in the character of Harvey, that he sided with the opponents of Aselli, and would not even be convinced by the demonstrations of Pecquet and Vesling. How different the conduct of his own adversary, Plempius, who, after having long contended against the circulation, made a voluntary acknowledgment of his error, and freely embraced the new doctrine; and who, upon the present occasion, displayed the same amiable candour. In 1651, Olaus Rudbeck discovered the absorbent vessels of the large intestines, and remarked, that the supposed lacteal vessels of the liver served only to convey a lymphatic fluid to the hepatic glands; whence he conjectured, that the received opinion concerning the assimilating powers of that organ was altogether wrong. Shortly afterwards, Glisson and Wharton produced their respective works on the Liver and on the Glands, in which their structure and functions were more fully described. The latter gave the first account of the ducts of the parotids. Experiments were undertaken by Lower, Drelincourt, Lister, and Musgrave, to determine the motion of the chyle, and the changes to which it is subjected in its course; and before the close of the century the anatomy of the absorbent system was brought to a great degree of perfection by the labours of Nuck, Pacchioni, and Duverney.

The discoveries relating to the nervous system, and the organs of sense, were not less remarkable. Casserius, Sylvius, and Willis, applying themselves to the dissection of the brain, gave accurate views of its different parts, and of their relative position, and shewed the difference between the human brain and nerves, and those of other animals. Willis gave to the hypothesis of a nervous fluid a degree of consequence, which it had never before attained, supposing it to be the vehicle of the animal spirits, and the cause of various disorders, when it became vitiated; and he may be regarded as the precursor of Dr. Gall, in referring particular faculties of the mind to certain parts of the brain. His ideas on the former of these subjects were controverted by Malpighi, who investigating, with great industry, the nature of the cortical substance, shewed, that it extended to the innermost parts of the brain, and in some animals even to the *medulla oblongata;* that its structure was fibrous; and that the fibres of which it consisted united in the great commissure and medulla oblongata, and again diverged into the brain; whence he infers, that the brain is to be considered as the appendage of the spinal marrow. The *tunica arachnoides* was described by Blaes and Swammerdam; and Leeuwenhoek and Ruysch ascertained, by the microscope, and by injections, the vascularity of the substance of the brain. The theory of vision had received considerable improvement from the labours of Kepler, who had pointed out the true use of the crystalline lens, and shewn how the images of external objects were formed, in an inverted position, on the retina. A public experiment with the eye of an ox, which was made at Rome, in 1625, by the Jesuit Scheiner, fully confirmed Kepler's theory; but afterwards Mariotte, having found that the images of objects disappeared when they fell on the spot where the optic nerve enters the eye, called in question the sensibility of the retina, and maintained that the choroid coat was better calculated to receive and transmit the perceptions of sight; and a controversy arose concerning the actual seat of vision, which was carried on, with great eagerness, by Pecquet, Perrault, and St. Yves, and which had the effect of eliciting many valuable observations. The Newtonian discoveries, respecting the properties of light, contributed still more to the accurate analysis of the functions of the eye; and the treatises of Du Petit, Porterfield, and Zinn, which followed soon after, have left little for their successors to accomplish.

Passing over the improved descriptions which Casserius, Duverney, Riverius, Vieussens, and others, gave of the structure of the ear; the interesting experiments of Harvey, Malpighi, and Redi, on the generation of animals; the discovery of the seminal animalculæ by Leeuwenhoek; and the various discussions and theories to which they severally gave rise; we conceive that we have adduced sufficient proofs of the great increase which took place in anatomical knowledge, and of the indirect advantages which medical science derived from the application of mathematics, and from the improved methods of physical research, which came into use after the time of Bacon. Wherever the laws of mechanics were properly applied, as they were by Borelli to muscular motion, and by Kepler and his followers to the theory of vision, they explained and illustrated the phenomena of life; and even when they were transferred to questions, which they were altogether incompetent to determine, as in the calculations of Borelli, Keil, Hales, and Wintringham, respecting the action of the heart and arteries; they suggested and led the way to many luminous experiments. In these respects the mechanists had greatly the advantage over their chemical brethren, whose speculations being founded on vague and puerile hypothesis, and implying no acquaintance with the laws of nature, led only to an accumulation of errors.

Descartes had taught his followers to consider matter as purely passive, and to refer all the changes to which it is subjected to a spiritual cause: the union of body and spirit was, in his estimation, merely one of its modes, or accidental conditions. Malebranche, extending the Cartesian doctrine, endeavoured to explain more fully the nature of this union, and to shew that the soul had a more or less distinct consciousness of all the movements and affections of the body. The part which the animal spirits were made to perform has been already frequently noticed. From these tenets, the transition to the system which came to be afterwards developed by Stahl was very easy; and an attentive review of the progress of the opinions in question must convince every one that the Stahlian hypothesis, far from being entitled to the merit of originality which its author claimed, was nothing more than an offspring of the Cartesian philosophy. Educated under Wedel, who was a devoted adherent of Sylvius, and an assiduous teacher of his doctrines, Stahl began very early to question the sufficiency of those chemical explanations, which he heard applied to all the phenomena of life. It appeared very wonderful to him, that the humours of the body, which are, of themselves, so disposed to putrefaction, should yet so seldom fall into that state; and that the daily presence of so many saline substances, as we are in the habit of receiving in our food, should produce so few symptoms of acrimony. He also remarked the great influence which the passions of the mind had in the production of diseases, and their instantaneous operation, in general, on the corporeal frame. The intervention of animal spirits he conceived to be a very unsatisfactory supposition; and all the attempts which had been made to explain the theory of life on pure chemical and mechanical principles he held very cheap. Taking the passiveness of matter for the basis of his system, he maintained, "that the body, as body, had no power to move itself, but was put in

motion

motion only by immaterial subſtances; that all motion, therefore, was immaterial, and a ſpiritual act." The origin of all the actions of the living ſyſtem, by which it is enabled to preſerve itſelf, and to fulfil the ends for which it is created, muſt, according to Stahl, be ſought for in the *ſoul*, or immaterial principle which animates it,—the nature, or ψυχη of the ancients. A little obſervation will teach us, that many ſenſations are experienced, and many corporeal actions performed, which are either altogether unnoticed at the time, or of which we have only an obſcure conſciouſneſs; but in which it cannot be doubted, that the mind more or leſs participates. Finding this to be the caſe with reſpect to our perceptions, and the anatomical movements, as they have been termed, of the body, Stahl thought himſelf juſtified in ſuppoſing the ſame power to preſide over all the other functions, and accordingly referred the performance of digeſtion, abſorption, and aſſimilation, to the immediate agency of the ſoul. As the ſoul regulates thus inceſſantly the ordinary movements of the animal machine, and is thus conſtantly intent on its preſervation, the ſame ſalutary vigilance may be naturally expected during diſeaſe. In fact, diſeaſe may be generally ſaid to conſiſt in a deranged idea (*perturbata idea*) of the regulation of the animal economy; and this poſition Stahl conceives to be proved by the greater frequency of diſeaſes in the human ſpecies, than among the inferior animals, and from their attacking, moſt readily, thoſe perſons who are endowed with a high degree of ſenſibility. Several ſecondary cauſes, however, appeared neceſſary to the further illuſtration of this peculiar pathology, among which plethora had the moſt extenſive agency aſſigned to it. To this condition, Stahl believes that there is a conſtant tendency in the human body, and that it proceeds from the quantity of aliment received being always greater than is neceſſary for the ſupport of the organs: it ſhews itſelf in different parts of the frame, at different periods of life; in infancy, for example, in the head; afterwards in the lungs; and finally in the digeſtive organs. Hemorrhages were, for the moſt part, occaſioned by an effort of nature to moderate this diſpoſition to plethora, by what Stahl called the *tonic vital action*; as exemplified in menſtruation, and in the hemorrhoidal diſcharges which occur in advanced age, and which Stahl aſcribed to the tonic action of the *vena portæ*, the ſource of the great majority of chronic diſtempers, "porta malorum." Rejecting, as altogether unfounded, the doctrine of the acidity and alcaleſcence of the humours, Stahl inculcated the neceſſity of ſtudying, in diſeaſe, the organic movements of the ſyſtem, and of obſerving the proceſſes by which nature effects a cure. Fever, according to his view, was merely an autocratic effort of nature, to conquer the morbific cauſe, and to expel it from the body, and all the ſymptoms, not excepting *rigor*, were only ſo many proofs of the tonic action which was thus excited. Congeſtions were ſuppoſed, in contradiſtinction to obſtructions, to reſult from an afflux of the fluids occaſioned by the ſame tonic power; when obſtruction followed, or when the object of the congeſtion, *i. e.* evacuation, was not accompliſhed, inflammation took place; and the tendency of the violent actions, which accompanied it, was to diſperſe the obſtructed humour. If this end was not attained, the obſtructed matter became vitiated, and pus was formed. Hypochondriaſis, gout, melancholy, and almoſt all cachectic diſorders, were attributed to a diminution of the tonic power of the *vena portæ*, and the conſequent ſtoppage of the blood in it; while ſpaſmodic diſeaſes were thought to indicate an exceſs of the general tonic power of the ſyſtem.

In the treatment of diſeaſes Stahl proceeded in conformity to theſe views. The chief duty of a phyſician, he maintained, was to watch the healing efforts of nature; to leave the cure to them, when they ſeemed adequate to its accompliſhment; but to aſſiſt them when they were too feeble, and to moderate their violence when they were too powerful. Thus, holding evacuation to be indicated in fevers, he recommended the aſſiduous employment of ſuch means as were likely to promote it, particularly diaphoretics. Purgation, indeed, he conceived to be ſeldom neceſſary or uſeful; but veneſection he had little heſitation in adminiſtering, as it ſerved, in his opinion, to bring about the criſis, and to favour the efforts of nature to relieve herſelf from the ſuperfluity of blood; it might, however, prove injurious, if due attention was not afterwards paid to the excitement of ſweating. The Peruvian bark was admitted by Stahl to operate in the cure of intermittents by its aſtringent qualities; but he believed it rather ſuppreſſed the diſeaſe, than effected its complete removal. Generally ſpeaking, his favourite remedies were evacuants, ſuch as antimony, aloës, rhubarb, and jalap; to the uſe of chalybeate medicines in chronic complaints, he objected, that they cauſed too powerful contractions of the parts; and opium tended, as he thought, to counteract too much the tonic vital action; yet he preſcribed hyoſcyamus, without any ſcruple.

"The ideas of Stahl," obſerves M. Cabanis, "have, in general, been very imperfectly underſtood; we may even aſſert, that they have been almoſt equally disfigured by his cenſurers and by his admirers. The cauſes of this miſunderſtanding deſerve to be detailed in a particular work. It would be uſeful to exhibit the Stahlian ſyſtem, in more determinate points of view, than the author himſelf could poſſibly have done. Hitherto the points, by which it is diſtinguiſhed from the doctrines of the ancients, and thoſe by which it is related to them, have never been preciſely aſcertained. Perhaps, too, it would be adviſable to conclude a work of this deſcription by a ſyſtematic view of the progreſs of medical ſcience ſince the time of Stahl, and of the advances which we have reaſon to expect at no very diſtant period. It would probably reſult from this inveſtigation, that the reforms, which have been already effected, and thoſe which may be hereafter accompliſhed in the ſame ſpirit, muſt be aſcribed, in a great meaſure, to this extraordinary man; both on account of the ſound ideas which he directly eſtabliſhed, and of the impulſe which he communicated to public opinion. It would too, I am perſuaded, appear, that notwithſtanding the haughty manner in which the adverſaries of Stahl have attacked him; notwithſtanding the aukwardneſs with which ſome of his diſciples have defended, explained, and commented upon his works; ſtill his influence has not been leſs powerful in medicine than in chemiſtry, and that to both ſciences he has rendered everlaſting ſervices." Coup d'Œil, p. 148—9.

Of Stahl's merit as a chemiſt we ſhall have occaſion to ſpeak at large in a future volume; in this place we ſhall be content with obſerving, that, although he effected a complete revolution in chemical ſcience, and continued to lecture upon it, with great applauſe, during the whole period of his academical career; yet he had the good ſenſe to refrain from all application of chemiſtry to medicine, and repeatedly cautioned his diſciples of the futility of any ſuch attempt; contending, that the true theory of phyſic conſiſts in the ſtudy of the vital actions, and has little or nothing to do with the laws of mechanics, with the minute anatomy of the ſolids, or with the mixture of the fluids; that its chief object is to aſcertain by experience the laws of organic life; that it is therefore little elſe than rational empiriciſm;

and

and in the neglect of this empirical method is to be found the origin of all the controversies of physicians. Notwithstanding these salutary admonitions, it is evident that Stahl himself forsook this empirical method, when he gave "to an airy nothing a local habitation and a name," by personifying the principle of life, and ascribing to the direct agency of a rational intelligence all the corporeal functions of the system. Some persons, it is true, have imagined that they could perceive, through the obscurity of Stahl's style, the glimpses of a more enlightened physiology, and Cabanis even contends that Stahl selected the term *anima* or *soul*, merely in order to save himself from persecution; not as thinking it by any means the best calculated to express his views: but this would have been a species of deception, to which it is not probable that the haughty spirit of Stahl would have stooped; and nothing appears in his writings to warrant the belief, that he wished the phrase in question to be understood in any but the literal and vulgar acceptation.

Stahl's contemporary and colleague, Frederic Hoffmann, though endowed with less genius, was his superior in learning, and in the faculty of displaying it to advantage; and he accordingly obtained, as a teacher, a much higher degree of repute. But while he professed himself the enemy of hypothesis, and the follower of Hippocrates, he gave in to many of the prevailing errors, and supported many doctrines which had no foundation in truth. Mathematical studies had taught him to reason closely; and, if the premises be admitted on which he constructed his system, the consequences must be allowed to be, for the most part, correctly deduced: but in his illustrations he is extremely diffuse and fatiguing; and his repetitions are endless. At first a follower of the mechanical sect, he seems to have gradually approached to the opinions of Stahl, and that at the very time when he was engaged in controverting them, and was exclaiming against their supposed atheistical tendency. His theory, accordingly, is a heterogeneous mixture of speculations, few of which would be now deserving of notice, were it not for the celebrity of their author, and the tone which he gave to succeeding theorists. Vindicating the active qualities of matter, Hoffmann considered the human body as a machine, which is governed by the laws of mechanics, and put in motion by a nervous fluid, or ether, contained in the brain and nerves, and the blood. The heart and all the organs of the system were supposed by him to receive their strength, their tone, their contractile and elastic power, from this subtle fluid: he even ascribed to it a certain degree of intelligence, "vim sensitivam et imaginativam," by which each particle is enabled to form a correct idea of the mechanism of the body, and to regulate its agency accordingly! Medicine, he believed, was to be improved, not so much by experience, as by the skilful application of mechanical principles, and by the sedulous study of proximate causes. All disease he held to consist in irregularity of action: when too violent, spasms were produced; when too weak, atony was the consequence. Yet he agreed with Stahl in referring much to obstructions of the humours, particularly in the *vena portæ*; but maintained that they always implied relaxation, or atony, of the vessels. He even admitted the doctrine of corruption of the fluids; ascribing gout, rheumatism, calculi, and cutaneous diseases, to acids generated in the body, and converted into neutral salts, upon admixtion with the blood. Plethora was also allowed by him to be one of the chief causes of disease. The *spasm*, or constriction of the membranous and minute vessels, particularly of the skin, by which the blood is repelled to the interior parts, and the heart and larger arteries are incited to greater action, till they are enabled to overcome the resisting cause, was, according to Hoffmann, the origin of every description of fever; and inflammation was explained by him on similar principles.

As a practitioner, Hoffmann appears to have been more successful than his rival, and to have had, indeed, a just title to that fame which he enjoyed. Though he inculcated the strict observation of critical days, yet he had the courage to maintain, in opposition to the universally received opinion, that it was not always necessary to wait for the concoction of the morbific matter in fever; for he believed the disorder might be sometimes stopped, in the commencement, by the administration of powerful means. Venesection was employed by him in all violent affections of the vascular system; and he trusted much to the antiphlogistic regimen in sthenic disorders. Among sudorifics he chose only the mildest; and drastic medicines were in little repute with him. The use of Peruvian bark in intermittents was rescued by Hoffmann from the contempt with which the Stahlians affected to view it; he demonstrated the great efficacy of chalybeates in various chronic complaints, and fully refuted the notion that they produced too great a constriction of the fibres. He investigated the nature of several of the most famous mineral waters; shewed their safety and utility in disorders for which they had been thought unfit; and taught to imitate them artificially. Warm and cold bathing were much commended by him for their virtues in restoring the proper tone of the system; and wine, camphor, and the well-known *liquor anodynus*, were favourite remedies with him in most chronic diseases: the last mentioned was generally used by him in the place of opium.

While Hoffmann was thus usefully employed in diffusing more sound practical doctrines among his contemporaries, Boerhaave was labouring, with equal zeal, and even with greater success, in the same path. Like Hoffmann, he began by commending the Hippocratic method; and, like him too, he soon deviated from it, by yielding to the influence of his early studies, and by acquiescing too much in the spirit of his age. He had enjoyed but little opportunity of acquiring a practical acquaintance with anatomy; and this want, as has been justly remarked, is perceivable throughout his writings. Fancying that the best system of physic would be that which reconciled all opinions, he sought to combine the doctrines of Hippocrates with those of Sylvius and Bellini, and was therefore, in the strictest sense of the word, an *Eclectic*, and not the founder of a new theory, as he has been sometimes considered. He refuted, it is true, many of the errors of the chemical school, and, in particular, the idea of a fermentation in the stomach and blood; but he embraced, in its fullest extent, the notion of an acid and an alkaline *cacochymia*: the tenets of the mechanists were adopted by him with less reservation. In general, however, less extravagant than his predecessors, he enlarged the boundaries of medical science by his observations; while, by the charms of his style and delivery, he gave a lustre and attraction to his doctrines, which procured him disciples from all parts of the world.

To this triumvirate, as they have been called, to Boerhaave, Stahl, and Hoffmann, pathology and therapeutics owe many of their greatest improvements. All succeeding systematics have borrowed more or less from their speculations: and, in certain universities, their theories, or at least modifications of them, are still taught. However fanciful the views of Stahl may at first sight appear, it cannot be doubted that they had the effect of fixing the attention of physicians on a most important branch of the animal economy, the influence

fluence of the nervous system upon the other organs of the body, and its co-operation in the production and cure of diseases. However much we may be tempted to laugh at Hoffmann's etherial fluid, and the sagacity and prudence which he ascribed to it, a careful examination of his writings will probably teach us, that by this very hypothesis he was led to the discovery of the relations which he pointed out between the different functions of the living frame, and of the sympathies which are the consequence. Considering how little this part of pathology had been investigated, and by what erroneous notions the study of it was obscured, we must allow, that Hoffmann and Stahl had no small merit in opening the way to its illustration, though they afterwards may have cast, upon the object of their researches, the false colouring of their respective theories. Hoffmann, in particular, has collected many valuable observations, in his treatise "De consensu partium nervosarum," proving the reciprocal influence which the various organs exert upon one another, especially those which are connected by means of the sympathetic nerve.

Among the adherents of Stahl, Porterfield, Whytt, Bordeu, and Sauvages, are the most eminent. The last-mentioned is well-known as the author of the first methodical Nosology, a work of great labour and research, which, notwithstanding the imperfections of its arrangement, contains much practical information, and which has served as the model of all similar subsequent undertakings. Bordeu had the merit of pointing out the importance of the cellular membrane, and of determining many of its properties which had been overlooked; while Porterfield and Whytt endeavoured to trace the laws that govern the muscular actions of the body, and to shew their dependence on the nervous influence.

The majority of the physicians of the age, having studied under Boerhaave, or his immediate disciples, followed the system of the Dutch professor. But the new light which was thrown on physiological science by the experiments and the splendid discoveries of Haller, tended to wean them from opinions which were but little consonant to experience, and the fallacy of which they were now in many instances compelled to acknowledge. Boerhaave, in his posthumous work "De Morbis Nervorum," had espoused the ancient dogma of an ἐνορμων, or *impetum faciens*, which he figured to himself as an intermediate substance between matter and spirit, and to which he attributed all the sensations and motions of the animal frame. His nephew, Kaau-Boerhaave, developed more fully his ideas on this subject; and De Gorter and Gaubius, taking up the same views, and giving them somewhat greater precision, obtained for the hypothesis of a *vital principle* that distinction which, unfortunately for the interests of science, it has, till within these very few years, been allowed to claim in physiological disquisitions.

Such was the state of things, when Cullen ascended the professorial chair. Led, by the duties of his office, to review and examine the various systems of physic which were in vogue, he soon perceived the inconsistencies of the Boerhaavian theory, and accordingly resolved to abandon it. Stahl's doctrines, to which some of his contemporaries adhered, did not appear to him more satisfactory; and, in particular, he deemed them objectionable on account of the inert practice which they countenanced. Nor could he altogether assent to the system of Hoffmann, though he conceived it to approach nearer to the truth, and was induced to adopt some of its fundamental principles. Among others, he took up the doctrines of spasm and debility, from which he deduced all the phenomena of febrile disorders; and he endeavoured to confirm his theory by proofs drawn from the laws of the nervous system, and from the consideration of the remote causes of the diseases in question. Rheumatism was referred by him to a spasm of the muscular fibres, arising from an increased afflux of blood; but gout he conceived to originate in atony, especially in atony of the digestive organs. In these latter diseases, he rejected the idea of a peculiar morbific matter; yet in his explanations of certain other complaints, as, for instance, of scrofula, he had recourse to the supposition of an acrimony of the fluids. He laid much stress on the efforts of the *vis medicatrix naturæ*, advocated the hypothesis of a nervous fluid and vital principle, and ascribed to the brain a peculiar faculty, by which it was enabled to excite the muscles to action, independently of the mind, and to which he gave the name of *irritability of the sensorium*. As we have had frequent occasion to review the opinions of Cullen, in various parts of this work, especially under the article FEVER, we may be excused from entering more fully into detail in this place; particularly as there is so little essential difference between them and those of his predecessor Hoffmann, and as the great majority of them have been exploded by the more recent improvements in physiology. Cullen, indeed, seems to have been much in the same situation with Boerhaave, as to anatomical and physiological learning, of which many of his speculations betray a miserable deficiency. Yet his system continues to be taught, and, in some measure, to form the present creed of the Edinburgh school; a distinction which it would scarcely have maintained, had it not been for the transcendant merits of the author as a practitioner, and for the rational and consistent method of treating diseases which he inculcated.

In another point of view, however, the speculative doctrines of Cullen seem to deserve notice, *viz.* as having afforded the first hint of the Brunonian theory of *excitability*. In a passage of his "Institutions of Physiology," Cullen speaks of a state of *excitement*, or *collapse*, of the brain and nervous system, on which he supposes the strength or debility of the other parts of the body to depend; and in his other writings, he is constantly labouring to prove in what manner these conditions may be occasioned by the agency of various causes. Brown, seizing upon this idea, set about the formation of a new theory, according to which all the actions of life were to be referred to the *excitement* of the body by *stimuli*, and all diseases reduced to the two general heads of *direct* and *indirect debility*, or debility arising from a deficiency, or a previous excess of excitement. That the doctrine of morbid excitement is so far founded on truth, and that many of the leading symptoms of disease may be referred to it, we are not inclined to dispute; but when Brown proceeds to account for all the deviations from health upon this simple principle, we conceive that he has generalised too much, and evinced but small power of discrimination. The excitability and the excitement of the living body doubtless vary much at different times, and disease is often the consequence; but it is not true, as Brown contends, that when the excitement of any part has been unusually increased or diminished, a correspondent increase or diminution of excitement must take place in all the rest of the system: on the contrary, it will be found, that when one part or series of organs has been incited to greater action than common, the other parts generally exhibit a decrease of action; and *vice versâ*. The Brunonian theory, in truth, takes but a gross view of the laws of organic life; and, with respect to the classification of diseases, it cannot be considered as much more refined and satisfactory than the theory

theory of the *strictum* and *laxum*, as taught by Themison and his followers. To the practical maxims which its author laboured to establish, the same observation applies. Brown mistook a single property of animal matter for the primary cause of life and disease; neglecting the consideration of those various powers which the different organs possess, according to their peculiarities of structure, and overlooking entirely those laws by which they influence each other, and communicate or modify the affections to which they are severally liable. This has been the grand defect of almost all pathological systems; and it was not to be expected that Brown, whose practical knowledge was confined, and whose acquirements in general were superficial, should have outstripped his predecessors. Many of those who were most zealous in their devotion to his system, and who defended it most strenuously on its first promulgation, have found it so incompetent a guide at the bed-side of the patient, that they have deemed it advisable to qualify their belief in several essential articles; while others, as Frank and Reid, have been reduced to the necessity of completely recanting their faith. But we are, nevertheless, disposed to think, that the general spread of Brunonianism, especially on the continent, has had the beneficial effect of loosening the attachment of physicians to ancient prejudices, and of simplifying their complex, and too often incongruous, modes of practice. See EXCITABILITY.

Previous to Darwin, no one seems to have conceived the idea of applying the doctrine of *association* to the theory and the treatment of disease; although the tenets of Hartley were embraced by a large proportion of his countrymen, and his illustrations of the associative actions of the nervous and muscular systems were universally received. It is true that Hoffmann, and even some writers before his time, had remarked the sympathy, or *consensus*, which subsists between particular organs of the body; but their observations were blended with much erroneous hypothesis, and the rude state of physiological science, at the time, prevented them from discovering the extensive application of which they were susceptible. Darwin saw that the chief errors of preceding theorists had arisen from the partial views which they had taken of the animal economy; from their considering the living system as a simple whole, and not paying due regard to the reciprocal influence which the different organs, of which it is composed, have upon one another: he saw, too, that it was only by the same organic powers, by which the body is preserved and developed, that disease was generated, and formed, and finally removed from the system. Taking advantage of all the facts which had been accumulated by his predecessors, placing them sometimes in new lights, and at other times confirming and illustrating them by his own observations and experiments, he proceeded to the construction of a system of pathology and therapeutics, founded on the general laws of animated nature. Unfortunately, however, as he advanced in his design, he fell into many incongruities; and the difficulties increasing upon him, he was led to assume positions, which were not supported by any evidence, or countenanced by the slightest analogy. Such are his doctrine of the configurations of the organs of sense, many of his remarks on the exertions of the sensorial power, and the hypothesis of a retrograde action of the absorbents. Add to this, that the language which he employed is vague and inconsistent, and has occasioned much confusion and contradiction in his statements. Nor can we highly commend his division of diseases into those of irritation, sensation, volition, and association; the distinctions being frequently arbitrary and inconclusive, and the whole arrangement savouring of metaphysical subtlety. The best part of his works, and that in which he has evinced the most penetration, is unquestionably his account of the "Catenation of Animal Motions," and of the "Diseases of Association," particularly his "Theory of Fever." Rejecting, as illusive, all the explications which had been given of febrile disorders, on chemical and mechanical principles, Darwin has traced the succession of the symptoms of fever to the irregular actions of the nervous, vascular, and absorbent systems; shewing how the derangement of one part produces a similar or opposite affection of other parts, in consequence of the intimate connection of the organs in question, and the influence which they mutually possess. (See FEVER.) This was a great improvement in pathology, and it is only to be regretted that it should have been disfigured by the imperfections to which we have before adverted. Had Darwin possessed the profound anatomical knowledge, and the acute discernment of Bichat, he would have probably erected a system as finished in its parts, and capable of as extensive application, as the theory of gravitation; and as superior to the feeble creations of his predecessors, as the philosophy of Newton is to that of Descartes. But in his eagerness to explain every thing, he sometimes mistook words for facts; and his ardent imagination too often got the better of his judgment. It cannot, however, be doubted, that he had struck into the right path, and pursued it to a certain extent; and that his views have served to elucidate the nature of many disorders, which before had been greatly misunderstood. His writings contain a rich store of physiological observations, and many useful practical hints. If his theoretical doctrines have been regarded with distrust by his countrymen, they have experienced a more favourable reception on the continent: they have been partially adopted and improved upon by some enlightened physicians, particularly by Brandis and Hufeland; and when stripped of the hypothetical phraseology in which they are enveloped, they bid fair to become the foundation of a rational system of physic.

To complete the history of medical science, of which we have now pointed out the principal revolutions, it would be necessary to enumerate and investigate the merits of the different discoveries and improvements which have taken place, in all its different branches, during the present age. But not to speak of the delicacy of such an undertaking, and the abilities requisite for its correct and impartial performance, it is obvious that this would be, in a great measure, to describe the existing condition of the art, of which the plan of our work already comprehends the details. We shall, therefore, content ourselves in this place with remarking, that however much the continental nations may have extended the boundaries of the auxiliary sciences, and however great their claims in other respects may be, this country has taken a decided lead in the reform of medical practice. It may boast of setting the example to Europe in the employment of the cold affusion, and in the generally improved treatment of fever, in the revival and extension of the purgative method of cure, in the free use of mercury in cachectic disorders, and, above all, in the introduction of the vaccine inoculation. But we must acknowledge, that much still remains for us to accomplish; that the theory of medicine is yet in an unsettled state; that its practical application is too often wavering and fallacious: and taking a survey of the various fortunes of the art, we may say, with Bacon, that "*medicine* is a science, which hath been more professed than laboured, and yet more laboured than advanced; the labour having been rather in circle, than in progression."

We fubjoin a lift of the beft works on medical hiftory, with their refpective characters.

1. Hiftoire de la Médecine, où l'on voit l'Origine et les Progrès de cet Art—avec fig. par Daniel le Clerc, 12mo. Genev. 1696—4to. 3d Part, Amfterdam, 1723.

A work of confiderable merit for the time when it firft appeared. It gives a very full view of the doctrines of the ancients to the time of Galen, and, generally fpeaking, is written with great impartiality; though, on fome occafions, the author fhews a want of difcernment. "Nemo candidius et plenius fcripfit *Clerico*," was the favourable judgment of Haller.

2. The Hiftory of Phyfic, from the Time of Galen to the Beginning of the Sixteenth Century. By J. Freind. 2 Parts. London 1725—26.

This is a ufeful commentary on the hiftory of Le Clerc, and gives, befides, a minute account of the practice of the Arabian and middle ages; but the arrangement is defective.

3. J. H. Schulzii Hiftoria Medicinæ, a rerum initio ad A. U. C. 535 deducta, 4to. Lipf. 1728. Ej. Compendium Hiftoriæ Medicæ, a rerum initio ad Hadriani exceffum, 8vo. Halæ, 1742.

As far as this hiftory extends, it deferves unqualified commendation for the learning, the accuracy, and the difcrimination which it difplays. The account of the ftate of medicine in ancient Egypt is the beft which we poffefs; and the whole is compiled with fuch care, that, as Ackermann obferves, it would be difficult to detect a fingle error in it.

4. Dictionnaire Hiftorique de la Médecine ancienne et moderne. Par N. F. J. Eloy, 2de Ed. 4 tomes 4to. Mons. 1778.

A valuable book of reference, particularly for the lives and writings of the French phyficians.

5. Biographical Memoirs of Medicine in Great Britain, from the Revival of Letters to the Time of Harvey. By John Aikin, 8vo. Lond. 1780.

It was the defign of the author to furnifh a complete medical biography of Great Britain; but not meeting with fufficient encouragement, although this part of his labours is highly creditable, he has never accomplifhed his fcheme.

6. Inftitutiones Hiftoriæ Medicinæ. Auctore J. C. G. Ackermann, 8vo. Noriberg. 1792.

All Ackermann's writings bear the marks of great erudition and intelligence: his contributions to the new edition of Fabricius's "Bibliotheca Græca," have, in particular, thrown much light on the lives and writings of the Greek phyficians. It is to be regretted, that his elegant compendium of medical hiftory does not extend beyond the period of the Arabians.

7. Verfuch einer pragmatifchen Gefchichte der Arzneykunde, von Kurt Sprengel. 2te Aufl. 5 Th. Halle, 1800—1803.

This is by far the completeft hiftory of medicine which we have; but, though the labour of fourteen years, the execution of it is very unequal. Where Sprengel could avail himfelf of the labours of others, he has given a very fatisfactory view of the advances of the art; and his refearches concerning its condition among the Arabians claim the merit of fulnefs, and alfo, in fome meafure, of originality: but there is a great falling off in the latter parts of the work; and the concluding volume proves that the author has no pretenfions to any thing like a philofophic mind. His "View of the State of Phyfic during the laft ten Years of the Eighteenth Century," publifhed in 1801, is a hafty and extremely feeble performance, to call it by no feverer name. A French tranflation by Geiger, of the firft volume of the hiftory, appeared in 1809; but according to the account given of it by Millin, it is very carelefsly executed

8. Coup d'Œil fur les Revolutions et fur la Réforme de la Médecine. Par P. J. G. Cabanis, 8vo. Paris 1804

A work well worthy of perufal, on account of the philofophical fpirit in which it is compofed, and the ufeful views which it fuggefts concerning the reform of the art. The hiftorical part, however, is fuperficial, and badly arranged. A tranflation, with fome notes by Dr. Henderfon, was publifhed in 1806.

9. J. F. Blumenbachii Introductio in Hiftoriam Medicinæ Litterariam, 8vo. Gœtting. 1786.

10. Verfuch einer Chronologifchen Ueberficht der Literärgefchichte der Arzneiwiffenfchaft, verfaaft von D. J. G. Knebel, 8vo. Breflaw, 1799.

Thefe are two convenient manuals of the literary hiftory of medicine. The former efpecially is diftinguifhed by its neatnefs and accuracy.

The "Bibliothecæ" of Haller are too well known to require commendation in this place.

Among the minor and lefs important works the following may be mentioned.

J. C. Barchufen Hiftoria Medicinæ, in qua pleraque Medicorum Ratiocinia, ab Exordio Medicinæ ufque ad noftra Tempora pertractantur, 4to. Traj. ad Rhen. 1723. H. Conringii Introductio in univerfam Artem Medicam, 4to. Hal. 1726. J. C. Lettfom, Hiftory of the Origin of Medicine, an Oration, 4to. Lond. 1778. Walker's Memoirs of Medicine, Lond. 1799. R. Scuderi, Introduzione alla Storia della Medicina antica e moderna, 8vo. Venezia, 1800. Millar's Difquifitions in the Hiftory of Medicine, 8vo. Glafgow, 1811.

MEDICINE, *Clinical, Medicina clinica*. See CLINIC

MEDICINE, *Characters in*. See CHARACTERS.

MEDICINE, *Pandects in*. See PANDECT.

MEDICINE-*Cheft*, is a portable cheft, containing all forts of medicines neceffary for a campaign or voyage, together with fuch inftruments as are moft neceffary and ufeful for the purpofes of furgery.

MEDIEDNIK, in *Geography*, a mountain of Bofnia; 10 miles N. of Zwornik.

MEDIES, or MEDGIES, a town of Tranfilvania; 20 miles N. of Hermanftadt. N. lat. 46° 20′. E. long. 23° 58′.—Alfo, a town of Hungary; 10 miles N. of Zatmar.

MEDIETAS LINGUÆ, in *Law*, an inqueft impanelled, whereof the one half confifts of natives or denizens, the other of aliens.

It is ufed in pleas, wherein the one party is a ftranger, and the other a denizen. Solomon de Stanford a Jew, in the time of Edward I. had a caufe tried before the fheriff of Norwich, by a jury of *fex probos & legales homines, & fex legales Judæos de civitate Norvici*. See JURY.

This manner of trial was firft given by the ftat. 28 Ed. III. c. 13; before which it was obtained by the king's grant. He that will have the advantage of trial "per medietatem linguæ," muft pray it; for it is faid he cannot have the benefit of it by way of challenge. (Staundf. P. C. 158. 3 Inft. 117.) In petit treafon, murder, and felony, "medietas linguæ" is allowed; but for high treafon, an alien fhall be tried by the common law, and not "per medietatem linguæ." (H. P. C. 261.) And a grand jury ought not to be "de medietate linguæ" in any cafe. (Wood's Inft. 263.) A jury "de medietate" is alfo allowed in fome other cafes, by analogy to this rule "de medietate linguæ." As on a "Jus Patronatus," the jury muft confift of fix clergymen and fix laymen.

So alfo under ftat. 8 Henry VI. c. 12. againft embezzling records, the jury fhall confift of fix perfons, who are officers of any of the fuperior courts, and fix common jurors. So on a criminal trial in the univerfity courts, the jury muft be half freeholders of the county, and half matriculated laymen of the univerfity. See *Univerfity* Court. Bl. Com. book iv.

MEDIMNUM, Μέδιμνον, among the Greeks, a meafure of capacity holding fix Roman *modii* or bufhels.

MEDIN, in *Commerce*, called alfo Para, Fadda, Kata, and Mefria, a coin of Syria, of the fize of an Englifh filver threepence, worth a little above a halfpenny.

MEDINA, Peter de, in *Biography*, a Spanifh mathematician, who flourifhed in the fixteenth century, but of whofe perfonal hiftory we only know that he was a native of Seville, and the friend of the learned John Vafæus during his refidence in that city, who, in his "Chronicon Hifpaniæ," fpeaks in the higheft terms of his fkill in the mathematical fciences, and particularly as they were applicable to the art of navigation. His works are, 1. "Arte de Navigar," which met with a very favourable reception, and which was tranflated into the German, French, and Italian languages. 2. "Libro de las Grandezas y cofas memorables de Efpanna :" this work, which is defcriptive of the objects that are chiefly deferving of attention in Spain, Florian Docampo has tranfcribed into his "Hiftory of Spain." 3. "A Map of Spain," and many other pieces.

Medina, in *Geography*, a city of Arabia Felix, in the province of Hedsjas, about a day's journey from Jambo, on the Red fea. It is fituated in a fandy plain, of moderate extent, and furrounded with indifferent walls. It belongs to the fherriffe of Mecca, but of late has been governed by a fovereign of its own, of the family of Darii Berkad. At prefent the fherriffe rules it by a vizir, who muft be of the royal family. Before the days of Mahomet, it was called Jathreb ; but it was called Medined en Nebbi, the city of the prophet, from the period at which Mahomet, upon his expulfion from Mecca by the Koreifhites, took refuge here, and continued to make it the place of his refidence for the reft of his life. The tomb of Mahomet at Medina is held in refpect by the Muffulmans ; but they are not obliged to vifit it in order to the performance of any devotional exercifes; however, as the caravans from Syria neceffarily pafs near it in their return from Mecca, they turn afide to view the prophet's tomb. This tomb is fituated in a corner of the great fquare ; whereas the Caaba is in the middle of the fquare at Mecca. In order to prevent the people from fuperftitioufly offering worfhip to the afhes of the prophet, the tomb is inclofed within iron rails, and is only to be feen by looking through thefe. It is of plain mafon-work in the form of a cheft ; placed between the two tombs, in which are depofited the afhes of the two firft caliphs. It is an idle ftory, of unknown origin, that vaft magnets fupport the coffin of Mahomet in the air. Although it is not more magnificent than the tombs of the founders of moft other mofques, the building that covers it is hung with a piece of filk ftuff embroidered with gold, which is renewed every feven years by the pacha of Damafcus. This building is guarded by 40 eunuchs, chiefly for the fecurity of the treafure which is faid to be kept in it. This treafure confifts chiefly of precious ftones, the offerings of rich Muffulmans. But the account given of this treafure is blended with much fable. Niebuhr was informed by an eminent Arabian, that the guard was pofted for no other purpofe but to keep off the populace, who had begun to throw dirt upon the tomb, which they afterwards fcraped off, and preferved as a fort of relic.

Medina, a town of the Arabian Irak, feated on the Euphrates ; 60 miles N.W. of Baffora.

Medina, a town of Africa, the capital of the kingdom of Woolli ; it is a town of confiderable fize, furrounded by a high wall of clay, guarded by an outward fence of pointed ftakes and prickly bufhes, and containing from 800 to 1000 houfes. N. lat. 13° 38'. W. long. 12° 50'.—Alfo, a town of Africa, in Kaffan. N. lat. 14° 45'. W. long. 9° 15'.—Alfo, a fmall ifland in the Atlantic, near the coaft of Africa. N. lat 19° 45'.

Medina *del Campo*, *Methymna Campeftris*, an ancient town of Spain, in the province of Leon, fituated on the Zapardiel, a fmall river communicating with the Duero, between Toro and Tordefillas. This town was formerly celebrated for the refidence of feveral monarchs, and was then more confiderable than it is now, and both commercial and opulent. It has ftill three confiderable fairs, and feveral great privileges : it is free from all taxes, and the inhabitants have a right to fill all offices, both in the church and civil magiftracy, without the interference of the pope or the king. It is ftill large, though decaying ; it has a handfome fquare, in the middle of which is a fountain ornamented with a ftatue of Neptune. Medina del Campo is faid to have contained 14,000 families, though the number is now reduced to 1000. Although the population is much diminifhed, the ancient churches and convents are ftill remaining. According to Townfend it has 9 parifh churches, 70 priefts, 17 convents, and two hofpitals. The collegiate church, built of brick, is much admired for its roof. The old handfome houfe of the Jefuits is ftill to be feen. This town was the birth-place of the Jefuit P. J. Acofta, and of the philofopher Gomefius Pereira. Cardinal Ximenes had made this place one of his principal magazines for military ftores, collected with a view to curb the great nobility ; but when, A.D. 1520, the commons of Caftile fought redrefs of grievances, they feized the magazine, and defended the city with fuch obftinacy, that they forced Fontefca to retire and to leave them in quiet poffeffion of the ruins. The furrounding country is naturally fertile ; 20 miles S.S.W. of Valladolid. N. lat. 41° 23'. W. long. 5°.

Medina *Celi*, a town of Spain, in Old Caftile, on the Xalon, anciently called "Segoncia." N. lat. 41° 21'. W. long. 2° 27'.

Medina *del-Rio-Seco*, an ancient town of Spain, in Leon, fituated on a plain, watered by the river Sequillo. The ftreets are narrow and ill-paved. It has three parifh churches, four convents, an afylum for monks, and two well-endowed hofpitals. This place was formerly famous for its population, manufactories, and fairs, on which account it was furnamed Little India, in Spanifh India-Chica. In 1638, it was honoured with the title of city by Philip IV. It is furrounded by mountains, and the air of it is very falubrious. Its population, which is faid to have confifted of 30,000 perfons, is now reduced to a fourth of that number. The furrounding country abounds in corn and wine ; 15 miles W. of Palencia.

Medina *Sidonia*, a town of Spain, and capital of a duchy, in the province of Seville, anciently the fee of a bifhop, transferred to Cadiz ; 20 miles S.E. of Cadiz. N. lat. 36° 25'. W. long. 6°.

Medina *de los Torres*, a town of Spain, in Eftramadura ; 24 miles N. of Llerena.

MEDINET Fars, a ruined town of Egypt, fuppofed to have been the ancient Arfinoé, a little N. of Fayoum.—Alfo, a town of Egypt, on the right bank of the Nile, oppofite to Fefhn.

Medinet *Habu*, or, according to Mr. Bruce, *Medinet-Tabu*, a village of Egypt, near the W. bank of the Nile, where are found the remains of four temples, shewing the place where once stood the magnificent city of Thebes; 28 miles N. of Asna.

MEDINGEN, a town of Westphalia, in the duchy of Luneburg; 14 miles S.S.E. of Luneburg.

MEDINSK, a town of Russia, in the government of Kaluga; 32 miles N.N.W. of Kaluga. N. lat. 54° 58'. E. long. 53° 30'.

MEDIOLANUM, in *Ancient Geography*. See Milan.

MEDIR, in *Geography*, a town of Persia, in the province of Kerman; 60 miles E. of Sirjian.

MEDITATION, an act by which we consider any thing closely, or wherein the soul is employed in the search or consideration of any truth.

In our religion, it is used to signify a consideration of the objects and grand truths of the Christian faith.

Mystic divines make a great difference between meditation and contemplation: the former consists in discursive acts of the soul, considering methodically, and with attention, the mysteries of faith, and the precepts of morality; and is performed by reflections and reasonings, which leave behind them manifest impressions on the brain. The pure contemplative have no need of meditation, as seeing all things in God at a glance, and without any reflection.

When a man, therefore, has once quitted meditation and is arrived at contemplation, he returns no more; and according to Alvarez, never resumes the oar of meditation, except when the wind of contemplation is too weak to fill his sails.

MEDITERRANEAN, something inclosed within land; or that is remote from the ocean.

Mediterranean is more particularly used to signify that large sea which flows between the continents of Europe and Africa, entering by the straits of Gibraltar, and reaching into Asia, as far as the Euxine sea, and the Palus Mæotis.

The Mediterranean was anciently called the Grecian sea, and the Great sea. It is now cantoned out into several divisions, which bear several names. To the west of Italy it is called the Ligustic or Tuscan sea; near Venice, the Adriatic; towards Greece, the Ionic and Ægean of the ancients, now the gulf of Archipelago. From this last a strait, called the Hellespont, conducts to the sea of Marmora, the ancient Propontis; and another, now denominated the strait of Constantinople, the ancient Bosphorus, leads to the Euxine, or Black sea; which to the north presents the shallow Palus Mæotis, or sea of Azof, the utmost maritime limit of Europe in that quarter. The breadth of this sea is very various, from 80 to 500 miles; and its length is about 2000 miles to its farthest extremity in Syria. This wide expanse of sea is beautifully sprinkled with islands, and environed with opulent coasts. Tides are not perceivable, except in the narrowest straits; but, according to physiologists, there is a current along the Italian shore from W. to E., and towards the African coast in an opposite direction. In the Adriatic the current runs N.W. along Dalmatia, and returns by the opposite shore of Italy. (See Current.) The chief fisheries of this sea are those of the tunny, of the sword-fish, of the sea-dog, and of the diminutive anchovy. This sea is also the chief seminary of the *coral*; which see.

According to the learned Buffon, the Mediterranean sea was originally a lake of small extent, and had received, in remote ages, a sudden or prodigious increase, at the time when the Black sea opened a passage for itself through the Bosphorus, and at that period when the sinking of the land which united Europe to Africa, in the part that is now the straits of Gibraltar, permitted the water of the ocean to rush in. It was also his opinion, that most of the islands of the Mediterranean made a part of the continents, before the great convulsions that have taken place in this quarter of the world. Sonnini, at his request, and with a view of ascertaining his opinion, sounded the depth of the sea between Sicily and Malta; and he found the depth from 25 to 30 fathoms, and in the middle of the channel, where the water is deepest, never exceeding 100. On the other hand, between the island of Malta and cape Bon, in Africa, there is still less water, the lead indicating no more than from 25 to 30 fathoms throughout the whole breadth of the channel which separates the two lands.

The British trade carried on by means of the Mediterranean sea is of great consequence to Great Britain; and the permanent preservation of it depends on the possession of the town and fortifications of Gibraltar.

The counterfeiting of Mediterranean passes, for ships to the coast of Barbary, &c. or the seal of the admiralty office to such passes, is felony, without benefit of clergy. Stat. 4 Geo. II. cap. 18.

MEDITRINALIA, among the Romans, feasts instituted in honour of the goddess Meditrina, and celebrated on the thirtieth of September. They were so called from medendo, because the Romans then began to drink new wine, which they mixed with old, and that served them instead of physic.

MEDIUM, a Latin term, signifying *middle*, or *mean*.

Medium, in *Arithmetic*, or an *arithmetical medium* or *mean*, called in the schools *medium rei*, is that which is equally distant from each extreme; or which exceeds the lesser extreme, as much as it is exceeded by the greater, in respect of quantity, not of proportion.

Thus nine is a medium between six and twelve.

Medium, *Geometrical*, or *mean*, called in the schools *medium personæ*, is that where the same ratio is preserved between the first and second, as between the second and third terms; or that which exceeds in the same ratio, or quota of itself, as it is exceeded.

Thus, six is a geometrical medium between four and nine. See *Geometrical* Proportion.

This is a medium which virtue is supposed to observe; whence some call it *medium quoad nos*, as having a view to circumstances, times, places, persons, &c. Distributive justice observes a geometrical medium; commutative justice, an arithmetical one.

Medium, in *Botany*, a name which has been applied, at different times, to different species of Bell-flower; see Campanula. Linnæus retained it for the common biennial Canterbury bell, *Viola mariana* of old authors; because that plant had most generally received this appellation, and was universally believed to be the μηδιον of Dioscorides. The real μηδιον however, though sufficiently well figured under that name, with the synonym of *Mindium Rhasis*, in Rauwolf's Travels, t. 284, was never known to Linnæus, who erroneously referred Rauwolf's plant to his own *Campanula laciniata*. This error was detected a few years since, when the late Andrew Michaux sent seeds of the Mindium, or μηδιον, from Aleppo to Paris, and the fine plant they produced was described and figured by l'Heritier, in one of his Monographs, under the name of *Michauxia campanuloides*, in honour of the meritorious botanist and traveller who recovered this long lost rarity. We cannot but think, as we suggested at the time, with all possible respect for M. Michaux, that the ancient name *Medium* ought to have been retained for this newly recovered genus; nor could we wish to call it *Mindium*, with Adanson, the description in Dios-

X 2 corides

corides being, in this case, sufficient to leave no doubt; and *Mindium* is apparently a barbarous corruption of an Arabian writer. See MICHAUXIA and MINDIUM.

MEDIUM, in *Logic*, or *medium of a syllogism*, called also the *mean*, or *middle term*, by the Italians *mezzo termino*, is an argument, reason, or consideration, for which we affirm, or deny any thing: or, it is the cause why the greater extreme is attributed to, or denied of the less, in the conclusion.

Thus, in the syllogism, "Every good thing is to be desired: but all virtue is good; therefore all virtue is to be desired:" the term *good* is the medium: *virtue* the less extreme, and *to be desired* the greater.

It is called medium, as being a kind of mediator between the subject and predicate; or because the extremes are so disposed as to affirm or deny, by means hereof. Some call it *argumentum tertium*, a third argument; and others simply *argumentum*, as being the cause why we assent to the conclusion.

Mediums, or middle terms, are the things principally sought for, in discoursing; so that the invention of mediums makes the most essential part of logic. But the rules commonly given by logicians for that purpose, are mere impertinencies. In effect, no such rules can be given; nor have we any way of coming at such mediums or reasons, but by a close attention to clear ideas.

MEDIUM, in *Music*. Rousseau has made an article of this word in his dictionary, calling it "that part of the voice which is most distant from the extremities of its compass, and which is generally the most full, sweet, and powerful." The same might be said of the middle tones of most instruments. The top of the voice is the most brilliant, but almost always in falset; the bottom is grave and majestic, but less clear and compact. The middle tones of the voice are not only produced with the greatest facility, but are the most melodious and grateful to the ear.

MEDIUM, in *Mechanical Philosophy*, is that space or region through which a body passes in its motion towards any point.

Thus ether is supposed to be the medium in which the heavenly bodies move. Air is the medium in which bodies move near our earth. And water is the medium in which fishes live and move. And glass is also a medium of light, as it affords a free passage.

That density or consistence in the parts of the medium, by which the motion of bodies in it is retarded, is called *the resistance of the medium;* which, together with the force of gravity, is the cause of the cessation of the motion of projectiles.

MEDIUM, *Subtile*, or *Ætherial*. Sir Isaac Newton makes it probable, that, besides the particular aerial medium in which we live and breathe, there is another more universal one, which he calls an *ætherial* medium; vastly more rare, subtile, elastic, and active, than air; and by that means freely permeating the pores and interstices of all other mediums, and diffusing itself through the whole creation; and by the intervention of this he thinks it is, that most of the great phenomena of nature are effected. See ÆTHER.

This medium he seems to have recourse to as the first and most remote physical spring; and the ultimate of all natural causes. By the vibrations of this medium, he takes heat to be propagated from lucid bodies; and the intenseness of heat increased and preserved in hot bodies, and from them communicated to cold ones.

By this medium he takes light to be reflected, inflected, refracted, and put alternately in fits of easy reflection and transmission; which effects he also elsewhere ascribes to the power of attraction; so that this medium appears the cause and source even of attraction.

Again, this medium being much rarer within the heavenly bodies, than in the heavenly spaces, and growing denser, as it recedes farther from them, he supposes the cause of the gravitation of these bodies towards each other, and of the parts towards the bodies.

Again, from the vibrations of this same medium, excited in the bottom of the eye by the rays of light, and thence propagated through the capillaments of the optic nerves into the sensory, he takes vision to be performed; and so hearing, from the vibrations of this or some other medium, excited in the auditory nerves by the tremors of the air, and propagated through the capillaments of those nerves into the sensory; and thus of the other senses.

And again, he conceives muscular motion to be performed by the vibrations of the same medium, excited in the brain at the command of the will, and thence propagated through the capillaments of the nerves into the muscles; and thus contracting and dilating them.

The elastic force of this medium, he shews, must be prodigious. Light moves, according to the estimated distance of the earth from the sun in his time, at the rate of considerably more than 70,000,000 miles in about seven minutes; yet the vibrations and pulses of this medium, to cause the fits of easy reflection, and easy transmission, must be swifter than light, which is yet 700,000 times swifter than sound. The elastic force of this medium, therefore, in proportion to its density, must be above 490,000,000,000 times greater than the elastic force of the air, in proportion to its density; the velocities and pulses of the elastic mediums being in a subduplicate ratio of the elasticities and the rarities of the mediums, taken together. And thus may the vibration of this medium be conceived as the cause also of the elasticity of bodies.

Farther, the particles of this medium being supposed infinitely small, even smaller than those of light; if they be likewise supposed, like our air, to have a repelling power, whereby they recede from each other, the smallness of the particles may exceedingly contribute to the increase of the repelling power, and consequently to that of the elasticity and rarity of the medium, and so fit it for the free transmission of light, and the free motions of the heavenly bodies. In this medium may the planets and comets roll without any considerable resistance. If it be 700,000 times more elastic, and as many times rarer, than air, its resistance will be above 600,000,000 times less than that of water; a resistance that would make no sensible alteration in the motion of the planets in ten thousand years.

And is not such a medium better disposed for the heavenly motions than that of the Cartesians, which fills all space adequately, and without leaving pores, and is vastly denser than gold, and therefore must resist more?

If any ask how a medium can be so rare? let him tell how the air, in the upper regions of the atmosphere, can be above a hundred thousand times rarer than gold; how an electrical body can, by friction, emit an exhalation so rare and subtile, yet so potent, as though its emission occasions no sensible alteration in the weight of the body, yet it shall be diffused through a sphere of two feet in diameter, and carry up leaf-copper, or leaf-gold, at the distance of a foot from the electrical body: or how the effluvia of a magnet can be so subtile, as to pass a plate of glass without any resistance or diminution of force; yet so potent, as to turn a magnetic needle beyond the glass. That the heavens are not filled with any other, but such a subtile ætherial medium, is evident from phenomena: whence else are those lasting and regular motions of the planets and comets, in all manner of courses and directions; and how are such motions consistent confiftent with that refiftance which muft refult from that denfe fluid medium, wherewith the Cartefians fill the heavens?

The refiftance of fluid mediums arifes partly from the cohefion of the parts of the medium, and partly from the vis inertiæ of matter. The firft, in a fpherical body, is nearly as the diameter, or, at moft, as the factum of the diameter, and the velocity of the body. The latter is as the fquare of that factum. Thus are the two kinds of refiftance diftinguifhed in any medium; and, being diftinguifhed, it will be found that almoft all the refiftance of bodies, moving in ordinary fluids, arifes from the vis inertiæ. The part which arifes from the tenacity of the medium, may be diminifhed, by dividing the matter into fmaller parts, and making thofe more fmooth and flippery; but the other will ftill be proportional to the denfity of the matter, and cannot be diminifhed any other way, but by a diminution of the fame.

Thus the refiftance of fluid mediums is nearly proportional to their denfities; and thus the air we breathe, being about nine hundred times lighter than water, muft refift about nine hundred times lefs than water: as, in effect, the fame author has found it does by experiments on pendulums. Bodies moving in quickfilver, water, or air, do not appear to meet with any other refiftance but what arifes from the denfity and tenacity of thofe fluids; which they muft, were their pores filled with a denfe and fubtile fluid.

Heat, it is found, diminifhes the tenacity of bodies very much; yet does it not decreafe the refiftance of water fenfibly. The refiftance of water, therefore, arifes chiefly from its vis inertiæ; confequently, if the heavens were as denfe as water, or as quickfilver, they would not refift much lefs: if abfolutely denfe, without any vacuum, be the particles never fo fubtile and fluid, they would refift much more than quickfilver. A folid globe, in fuch a medium, would lofe above half its motion, while it moves thrice the length of its own diameter; and a globe not perfectly folid, fuch as the planets, would lofe more.

To make way, therefore, for the lafting motions of the planets and comets, the heavens muft be empty of all matter, except, perhaps, fome very fine effluvia, from the atmofpheres of the earth, planets, and comets; and fome fuch ætherial medium as we have defcribed. A denfe fluid can ferve for no purpofe, in the heavens, but to difturb the celeftial motions, and make the frame of nature languifh; and in the pores of bodies, it can only ferve to check the vibrating motion of their parts, wherein their heat and activity confift. Such a medium, therefore, unlefs we had fome evidence of its exiftence, muft be given up; and, that given up, the hypothefis of light confifting in a preffion falls alfo to the ground.

Medium *Participationis*, in the *Schools*, is that faid to be compounded of the two extremes. Thus, man, who is partly body, partly mind, is a medium by participation of the two extremes; fo is warmth the medium of heat and cold, &c.

Medium *Negationis*, or *Remotionis*, is that from which both extremes are derived; or it is a fubject capable of receiving both extremes, and yet not neceffarily poffeffed of either.

In which latter fenfe, the will is a *mean* with refpect to virtue and vice; and the underftanding, with refpect to knowledge and ignorance.

Medium *Quod*, or *Medium Suppofiti*, is fomewhat between the agent and patient, which receives the action of the one before it arrive at the other.

In this fenfe, air is a medium between the fire and the hand heated thereby.

Medium *Quo*, is the form, or faculty, whereby an agent produces an effect: in which fenfe, heat is faid to be the medium or mean whereby fire acts on the hand.

Medium *fub Quo*, is that which renders the power to act complete in general, without determining it to any particular object: in which fenfe, light is the medium under which the eye perceives any colour.

Medium *in Quo*, is that, by infpection whereof a power is produced in any thing, of knowing or perceiving another: fuch is a fpeculum, as it fhews an object; an image, as it reprefents the reality, &c.

MEDIUS, in *Geography*, a town of Perfia, in Farfiftan; 30 miles S.W. of Yefd.

Medius *Harmonicus*, Lat., in *Mufic*, with the Germans implies the middle found of a triad or common chord, as E in the chord of C. (Walther.) See Mediante.

MEDLAR, in *Botany*. See Mespilus.

Medlar, *Parfley-leaved*. See Service-*Tree*.

MEDLE, in *Geography*, a town of the ifland of Cuba; 62 miles N. of St. Yago.

MEDLERSLO, a fmall ifland in the N. part of the gulf of Bothnia. N. lat. 61° 13′. E. long. 21° 39′.

MEDLEY. See Chance-*Medley*.

Medley, in *Mufic*, during the early part of the laft century, a piece of pleafantry, or rather mufical buffoonery, was frequently practifed by Englifh compofers in compofing fymphonies from fragments of vulgar tunes, and popular compofitions, which were called *medley overtures*. Charke, Jack James, and even Arne, in his early days, condefcended to divert himfelf, more, perhaps, than the public, by thefe mufical falmagundies; of which, however, no one of thefe muficians can be ftyled the inventor. Dr. Pepufch feems to have given them the hint in his pleafant and appropriate overture to the Beggar's Opera; of which the firft movement is a burlefque of the beginning of Handel's overture in Otho; and the fubject of the fugue in the firft part of "I'm like a fkiff in the ocean toft," and the folo paffages for hautbois, the fecond part.

MEDMAN, in *Geography*, a town of the duchy of Berg, containing three churches for perfons of different religious profeffion; fix miles E.N.E. of Duffeldorp. N. lat. 51° 17′. E. long. 6° 43′.

MEDNIKI, a town of Samogitia, the refidence of the bifhop; 28 miles N.E. of Konigfberg.

MEDNOE, a town of Ruffia, in the government of the Tver, on the Tvartza; 32 miles W.N.W. of Tver.

MEDOC, a county of France, fo called before the Revolution, in form of a peninfula, between the Garonne and the fea, the north part of which is overflowed by the fea. On a rock at the mouth of the Garonne is a fine light-houfe, called "La Tour de Cordouan."

MEDOCTU, a fettlement of America, in New Brunfwick, fituated on the W. fide of St. John's river; 35 miles above St. Anne's. N. lat. 46° 12′. W. long. 67° 35′.

MEDOLA, a town of Italy, in the department of the Panaro; 18 miles S. of Modena.

MEDOLI, a town of Italy, in the department of the Mincio; 17 miles N.W. of Mantua.

MEDRA, a town of Africa, in Lower Guinea, capital of a country near the river Camerones.—Alfo, a town of Perfia, in the province of Mekran; eight miles N. of Kich.

MEDRASHEM, a town of Algiers; 40 miles S. of Conftantina.

MEDSHETISAR, a village, being one of the Perſian havens on the Caſpian, is ſituated, as is alſo Farabat, on the ſouthern coaſt, in the province of Mazanderan. Of theſe two villlages Medſhetiſar is the moſt convenient, from its vicinity to Balfruſch, capital of the province, where the Ruſſians and Armenians convey their merchandize: the traffic, however, is much diminiſhed on account of the impoſitions of the khan of Mazanderan. The chief productions of this country are ſilk, far inferior to that of Ghilan, rice and cotton, which are largely exported. Merchants from Kaſhan, Iſpahan, Schiras, and Khoraſan, reſort to Balfruſch, and bring for ſale the Perſian and Indian commodities.

MEDUA, a town of Algiers, at the foot of mount Atlas, in the midſt of ſprings; 180 miles S.W. of Algiers.

MEDVADITZA, a river of Ruſſia, in the country of the Coſſacks, which riſes about ten miles N. from Saratov, and runs into the Don, about eight miles N.W. from Spaſkaia.

MEDVEDIVA, a town of Ruſſia, in the government of Irkutſk, on the Ilim; 64 miles S.W. of Orlenga.

MEDVEZEI, a cape on the N. coaſt of Nova Zembla. N. lat. 77° 20′. E. long. 68° 34′.

MEDVEZHI, five ſmall iſlands of Ruſſia, in the Frozen ſea; 60 miles from the mouth of the Kolima. N. lat. 72° to 72° 20′. E. long. about 156°.

MEDVEZI, a ſmall iſland of Ruſſia, in the ſea of Ochotz, at the mouth of the river Uda. N. lat. 55° 10′ to 55° 16′. E. long. 137° to 138°.

MEDUKKA, a town of Arabia, in the province of Yemen; 36 miles S. of Saade.

MEDULLA, in *Anatomy*, the fat ſubſtance which fills the cavity in the middle of a long bone. See MEDULLARY *Syſtem*.

MEDULLA *Oblongata*, one of the diviſions of the contents of the cranium. See BRAIN.

MEDULLA *Spinalis*, the medullary cord contained in the canal of the vertebræ. See BRAIN.

MEDULLA, in *Vegetable Phyſiology*, the Pith of plants, is lodged in the centre or heart of the vegetable body, where it is as aſſiduouſly protected as the brain and ſpinal marrow of animals. In parts moſt endued with life, like the root, or eſpecially young growing ſtems or branches, the *medulla* is uſually of a pulpy ſubſtance; but tolerably firm though rather brittle. Its colour is pale green or yellowiſh, with a watery tranſparency, the ſubſtance being very juicy. Its juices partake but little, or not at all, of the peculiar flavour of the plant, they being more of the nature of ſap. Still there is no perceptible flowing from this part when wounded, at any time of the year, as far as we have obſerved. In branches or ſtems more advanced in growth, the *medulla* is found of a drier, more white, and evidently cellular texture. In this ſtate it is known to every body in the full-grown branches of Elder, and the ſtems of Ruſhes, *Juncus conglomeratus*, *effuſus*, &c. In theſe it is dry, highly cellular, ſnow-white, extremely light and compreſſible, though but ſlightly elaſtic. Such are its different appearances, at different periods of growth, in many common ſhrubs, as the Currant-tree, Lilac, Mock-orange, *Hydrangea*, &c. In the laſt-mentioned ſhrub, though nearly akin to the Elder, as well as in the *Aucuba japonica*, the pith is very abundant, and remains unuſually long in its primary green juicy ſtate. The pith of many annual ſtems, abundant and highly ſucculent while they are growing, becomes little more than a web, lining the hollow of the adult ſtem, as in ſome Thiſtles. Many Graſſes and Umbelliferous plants, as the Hemlock and Chervil, have always hollow ſtems, lined only with a thin ſmooth coating of pith, exquiſitely delicate and brilliant in its appearance. The inner part of ſuch hollow ſtems is, in ſome inſtances, divided into ſeparate cavities, by tranſverſe partitions. Such is the caſe at every joint, knot, or ſubdiviſion of the ſtem. There are a few graſs-like plants, with unbranched hollow ſtems, internally divided by numerous membranous partitions, perceptible to the touch in the living plant, and to the ſight in the dry one; witneſs *Juncus articulatus* and its allies, in which the longitudinal hollow of the ſtem is ſimple; and *Cyperus articulatus*, in which it is a congeries of parallel tubes. We mean not to ſay that the tubes in this laſt-mentioned inſtance are certainly medullary. They may or may not; but obſervations on the living plant could alone determine this. It is poſſible they may be ſap-veſſels, and that the tranſverſe ſtricture is not complete, ſo as to prevent the paſſage of fluids along this highly vaſcular ſubſtance. But as other ſpecies of this tribe have the central part of their ſtems filled with cells, or tubes frequently interrupted, through which no fluid can run, it is moſt probable that *Cyperus articulatus* differs from ſuch merely in having all its tubes interrupted at the ſame point of elevation, and that the aſſemblage of numerous partitions gives a frequently jointed appearance to the whole ſtem. *Andromeda acuminata*, Sm. Exot. Bot. t. 89, is found to have its hollow ſtem intercepted by very numerous tranſverſe partitions; and the ſame may be ſeen in other inſtances. The diſtinction between a hollow ſtem, only lined with *medulla*, and a ſolid one, entirely filled up with that ſubſtance, by no means indicates any material difference between the plants ſo circumſtanced. Some ſpecies of *Hieracium* have the one ſort of ſtem, others the other, and this difference is often of uſe, for ſpecific diſtinction, in that difficult genus.

It is much eaſier to deſcribe the appearances of the *medulla*, which are few and but little varied, than it is to underſtand the true nature, or phyſiology, of this part. There is ſcarcely any concerning which a greater variety of opinions, or at leaſt more oppoſite ones, have been held.

Du Hamel, an excellent obſerver, though not always a correct theoriſt, conſidered this part as not in any reſpect different from the reſt of the cellular ſubſtance, diſperſed through the vegetable body, and ſerving to hold its different parts together; nor did he attribute any particular function, in the vegetable economy, to any part of this ſubſtance.

Linnæus on the contrary thought the *medulla* the ſeat of life, and prime ſource of vegetation. He conceived that its vigour was the main cauſe of the propulſion of the branches. His lively fancy formed to itſelf an idea of this organ altogether his own, as a living body of peculiar vivacity and energy, ſtriving to enlarge itſelf in every direction, and ſucceeding beſt where it found leaſt reſiſtance. Thus he explains the growth of plants, and eſpecially of trees, at their extremities only; the cortical ſubſtance, as he terms it, of the vegetable being, (conſiſting of its wood and bark, including the vaſcular ſyſtem,) affording leſs reſiſtance where it is younger and thinner, while it derives energy itſelf from the powers of the ſubſtance it confines. His idea of the animal phyſiology was ſimilar. He conceived the brain and nerves of animals to be analogous to the pith of plants, and that it was confined by their cortical ſubſtance, for ſo he called their bones and muſcles, as the pith is by the more ſolid parts of plants. He thought he traced the origin of the ſtamens, or male organs of vegetables, to their wood; and that of the piſtils, or female ones, to their pith. Hence he deduced

deduced a fine fanciful hypothesis, that the mule offspring of crofs impregnation fhould refemble its father in external habit and characters, and its mother in internal qualities, which opinion he alfo extended to the animal creation; nor did he want facts to fupport it. Both kingdoms were ranfacked to fupply them; for fome facts may be found to fupport any hypothefis, any at leaft conceived by a mind fo able, ingenious, and intelligent as that of Linnæus. Mule animals, whether thofe properly fo called, produced between different fpecies, or whether thofe engendered between varieties of the fame fpecies, are often found to refemble the father in their form or coat, while their conftitution and difpofition are more like the mother. The fame thing may be obferved in mule plants. Linnæus is unqueftionably right in attributing the origin of the fubftance of the feed of plants to the female part of the flower, the function of the pollen being only to communicate life, or a power of vegetation, to the embryo, and not to convey any fubftance, or corpufcule, out of which the rudiments of the future plant are to be formed. At leaft this feems the moft reafonable opinion, even from a contemplation of the experiments of thofe who have laboured to overfet altogether his doctrine of the fexes of plants. It is difficult to fay whether the embryo of a feed be formed at all before impregnation, becaufe, if formed, it is very foon obliterated in cafe impregnation fails, a mere cavity being found in its place when the feed is at all advanced. But we have feen much more reafon to believe its obliteration, rather than the contrary; and in moft cafes of non-impregnation, the cotyledons are obliterated alfo. See COTYLEDONES, EMBRYO, and FECUNDATION *of Plants*.

In another office which he attributed to the *medulla* or pith, Linnæus was unqueftionably miftaken. He thought it the origin of the wood; believing that a layer was every year added internally to the body of a tree from this fubftance. Du Hamel refuted this opinion, by experiments, which clearly proved the wood to be depofited by the bark, as we have explained in the articles CORTEX, and CIRCULATION *of the Sap*.

But while we thus reject opinions of the great Swedifh naturalift, which have been proved to want a folid foundation, it may be worth while to examine how far his general idea of the importance of the *medulla* may be defenfible. No one can deny that there is a great analogy between this part and the nervous fyftem of animals, with refpect to fituation and protection, as well as in its general uniformity of appearance and texture in widely different orders of plants; while the differences in thefe refpects which it exhibits in other tribes, are not at all greater than thofe found in the nervous fyftems and brains of different claffes of the animal kingdom. If, moreover, it be faid, that the pith is of too fimple a conftruction to allow a belief of its being of fo great importance to the vegetable conftitution, as to be the feat of life, or immediate organ of vegetation; furely we are as little able to difcover any thing in the form or texture of the brain and nerves, to account for their wonderful but undeniable properties. Scarcely any phenomenon in the animal frame is lefs intelligible, than the change in the pith of a plant from its fucculent ftate, to that dry congeries of an infinite number of clofe cells or veficles, impervious to fluids, and having no communication with each other. Yet the moifture efcapes by no means readily from the pith in its juicy ftate; for a thin flice of it in that ftate dries very flowly. The ingenious Mr. Knight has fuppofed the *medulla* to be a refervoir of moifture, to which the growing vegetable may have recourfe, when its fap-veffels are occafionally exhaufted by inordinate perfpiration. "Plants," fays this excellent writer, "cannot, like animals, fly to the fhade and the brook." This is undoubtedly true; but, inftead of fuch a refource, their leaves when exhaufted droop, or fold over each other; fo that their pores are contracted, and the very check which their energy receives prevents further exhauftion, and gives time for frefh fupplies from the root. Mr. Knight has indeed fhewn that the part in queftion may, occafionally at leaft, be difpenfed with, and removed from a branch without injuring it; but, on the other hand, he has more recently fhewn the importance, if not of the *medulla*, of its analogous organ, the cellular fubftance; having found that fubftance capable, as he thinks, of affuming the vafcular ftructure, and actual vegetation, of what Linnæus terms the cortical fubftance of a plant.

The writer of the prefent article has always been partial to the opinion of the *medulla* being, fome how or other, an organ fubfervient to the vital energy of the vegetable frame; but we can ftill lefs, if poffible, comprehend its mode of action, than that of our own brain and nerves. It is branched off and diffufed, like the nervous matter, to every part of the vegetable body, and hence may eafily be fuppofed to give life and vigour to the whole, though, no more than nerves, the organ or the direct fource of nourifhment; for its ftructure is fuch that it can tranfmit no fluids for that purpofe from the vafcular fyftem; at leaft not in any way that we can comprehend, till it has taken upon itfelf a different organization from what is natural to it. The pith however is certainly moft vigorous and abundant in young and growing branches, and muft be fuppofed fubfervient, in fome way or other, to their increafe. Mr. Lindfay of Jamaica (fee LINDSÆA), many years ago communicated a paper to the Royal Society, which, for fome reafon unknown to us, was never printed, the object of which was to prove a medullary knot in the leaf-ftalk of the *Mimofa pudica*, or Senfitive Plant, to be the feat of that remarkable irritability for which the plant in queftion is celebrated. We are not however able to trace any thing of this nature in the ftamens of the Barberry, which are no lefs remarkable for their irritability. Nor can we trace, to any great extent, the nervous fyftem of the infect tribe, even where we are not prevented by the minutenefs of the object of our examination; though the animals of that tribe yield to none in the fufceptibility and energy of their nervous fyftem. In both cafes the tranfparency of the parts may account for this difficulty.

We can therefore only reafon by analogy concerning the functions of parts, whofe ftructure cannot be afcertained, much lefs their mode of action. We fhall conclude this article with the mention of one phenomenon, eafily obfervable by any perfon who will beftow attention upon it. There are feveral fpecies of Grafs, amongft which are the Common Cat's-tail, *Phleum pratenfe*, and the Floating Fox-tail, *Alopecurus geniculatus*, whofe nature is to have an entirely fibrous root. Their proper ftation is in moift, or even watery fituations. But if they chance to eftablifh themfelves in ground whofe degree of moifture varies occafionally, or efpecially in very dry fpots, as on the top of a wall, they acquire bulbous roots, of a very juicy nature. This is evidently a provifion of Nature, to guard the plant againft deftruction from drought; as the tribe of naturally bulbous plants are, for the moft part, intended to occupy dry, fandy, or barren ground, under a burning fun. The naturally bulbous grafs *Poa bulbofa*, if cultivated in the rich and regularly watered foil of a garden, gradually lofes its bulbous habit, becomes exceffively luxuriant, and in time perifhes, in confequence of exhauftion from that very luxuriance, to which the annual formation of bulbs, in its proper fandy fituation, is a feafonable check. All thefe inftances furely prove

prove the accumulation of *medulla* in ſuch bulbous roots, to be equivalent to an accumulation of vital energy. They cannot be mere reſervoirs of moiſture, for all that they can poſſibly contain is not adequate to the ſupply of a few minutes perſpiration from the herbage. They may indeed huſband that moiſture, ſo as to render the ſcanty ſupplies obtained by the fibres below, or by abſorption through the leaves, ſufficient to keep the half-ſtarved plant from abſolute deſtruction; their own extraordinary luxuriance proving the ſalvation of the parts which they ſeem to ſtarve, but to which they are a neceſſary and certain reſource. The juſt conſideration of fleſhy roots in general will be found to illuſtrate this ſubject; for though thoſe of biennial plants muſt be conſidered as reſervoirs of nutriment, hoarded up by the growth of the firſt ſeaſon, for the inordinate ſupply of the next; the phyſiology of perennial bulbous roots ſeems to indicate, that all are likewiſe reſervoirs of vital energy, of which the *medulla* is the immediate organ, and probably the excluſive reſidence. S.

MEDULLARY ARTERIES, in *Anatomy*, the arteries diſtributed on the ſubſtance which fills the interior of bones. See MEDULLARY *Syſtem*.

MEDULLARY *Subſtance*, is the white matter of the brain and nerves. See BRAIN.

MEDULLARY *Syſtem*, is the expreſſion employed by Bichat to denote the tiſſue that occupies the interior of the bones. Its organical arrangement, vital properties, functions and diſeaſes, are imperfectly underſtood. Some remarks on it will be found under the article BONE. It is found only in the bones, and its uſes ſeem only relative to thoſe organs: yet its organization and properties are ſo different as to juſtify us in conſidering it ſeparately.

There are two kinds of it very diſtinguiſhable from each other: one occupies the cellular ſtructure in the extremities of the long bones, and in all the interior of the ſhort and flat bones: the other is found only in the middle of the former.

The firſt appears to conſiſt of the ramifications of thoſe veſſels, which enter by numerous ſmall holes of the ſurface into the common cellular tiſſue of the bone. They divide very minutely on the internal ſurfaces of the cells, producing the red appearance which characterizes that part, and which is more ſtrongly marked in proportion as the ſubject is younger. To them, and the blood which they contain, is owing the red colour of the powdery ſubſtance produced in ſawing through a bone. Fine injections propel the blood contained in this tiſſue, and make it appear in the adult as red as that of the fœtus when uninjected.

Authors have generally admitted the exiſtence of a fine membrane in theſe bony cells, and have aſſigned to it the office of exhaling the medullary fluid. Bichat repreſents it as a merely vaſcular texture, without any continuous ſurface; and obſerves, that the bone itſelf, in many points, is in contact with the medullary fluid. It poſſeſſes merely the organic ſenſibility and contractility neceſſary for the ſecretion of its fluid, and is diſtinguiſhed in that reſpect from the medullary ſyſtem of the middle of long bones, which is the ſeat of well-marked animal ſenſibility. There is no ſign of pain when it is irritated in a living animal. If it be very extenſively injured, necroſis may enſue: but ſmaller injuries have not this conſequence. Bichat perforated the extremity of a long bone in an animal, and then introduced a hot wire: it healed without necroſis.

The vaſcular network forming this ſyſtem is obſcured in the cartilaginous ſtate of the bone by the gelatine: as that is removed, the cells and veſſels become manifeſt. In the fœtus, and in the early years of life, it contains no oily fluid: at this time the blood is more abundant, and the cells are filled with ſome fluid, of which the nature is not well underſtood. Medullary oil is afterwards depoſited, and its proportion increaſes until the growth is completed. The cellular ſtructure of an adult bone expoſed to a pretty conſiderable heat parts with a large quantity of oily fluid: the ſame experiment tried on a fœtal bone produces only deſiccation of the tiſſue from evaporation of its fluids. When the extremity of a long bone of the adult is ſet on fire, the contained medullary ſubſtance keeps up the combuſtion; in the fœtus, the bone ceaſes to burn as ſoon as it is removed from the fire, as the fluids will not maintain the combuſtion. The bones, when dried, remain white and dry in the fœtus: they are yellow and greaſy in the adult at their extremities. Ebullition extracts much oil from the cellular tiſſue of adult bones, but none from thoſe of the fœtus.

The ſecond medullary ſyſtem occupies the large cavity in the centre of the long bones. Each of ſuch cavities is lined by a thin membrane, prolongations of which cover the thin portions of cellular tiſſue that project into the cavity, or paſs from one ſide to the other, and form cells in which the medullary fluid is contained. The ſituation in which it exiſts, gives to it, when conſidered altogether, a nearly cylindrical form.

It does not appear that the ends of this ſyſtem have any communication with the former; the two are ſeparated by a marked line of diſtinction, and not gradually confounded: yet it is difficult to prove the point clearly.

The great delicacy of the membrane conceals the nature of its texture: it cannot be referred either to the ſerous, mucous, or fibrous claſs, and has no analogy in its functions, &c. with the perioſteum, to which it has been often compared. A principal artery enters at the chief hole of each long bone, and ramifies on this membrane. Its branches give it, in the fœtus, a reddiſh colour, which diſappears afterwards. Expoſure of the containing cylinder to fire renders the membrane more apparent by corrugating and curling it up.

We have no means of bringing the properties that ariſes from ſtructure (proprietés de tiſſu) in this ſyſtem under our obſervation.

It enjoys animal ſenſibility in a very conſiderable degree, as we may prove by introducing a probe into the medullary cavity of a bone, by injecting an irritating fluid, or uſing any other mode of irritation.

The ſecretion and abſorption of the medullary fluid prove the exiſtence of organic ſenſibility, and of inſenſible organic contractility.

It is obvious from the preceding account, that the vital powers are more active in this than in the bony ſyſtem, conſequently that the vital phenomena muſt be more rapid, and the diſeaſes leſs prone to aſſume the chronic form, than thoſe which affect the bones.

The medullary membrane appears to exiſt in the cartilaginous ſtate of the middle of long bones; but gelatine is then depoſited in it, ſo that the whole bone is homogeneous in appearance. When oſſification begins, the gelatine is abſorbed, and the medullary cavity formed: the membrane admits red blood. At firſt, however, no oily matter is depoſited in the cells: inſtead of it, there is a reddiſh mucilaginous fluid, which exhibits nothing of a greaſy appearance when preſſed between the fingers. No particles of oil ſwim in the water after it has been boiled. The middle of a long bone expoſed to heat burns with the formation of inflamed drops: nothing of this kind occurs in the fœtus.

The function of the medullary membrane is to depoſit, by exhalation, the medullary fluid, and to convey it again into the blood by abſorption. It muſt therefore poſſeſs

exhalants

exhalants and abſorbents as well as blood-veſſels, although we cannot demonſtrate them anatomically. In this point of view the medullary ſyſtem reſembles the fat. It is hardly poſſible for us to know whether the exhalation be augmented or diminiſhed by any cauſes. It is however certain, that in phthiſis, dropſy, or other affections in which extreme general debility is produced by a gradual reduction of the vital powers, the medullary fluid loſes its eſſential characters, and aſſumes an appearance altogether different from its natural one, without any alteration in the texture of the membrane. It has a mucilaginous or gelatinous appearance, almoſt like that of the fœtus.

That the medullary membrane has a cloſe connection with the nutrition of the bone is rendered evident by the experiments of Troja, in which it is ſhewn that its deſtruction is followed by the death of the bone, and the formation of a new one, to which the perioſteum ſerves as a nutritive parenchyma. The common way of proceeding has been to ſaw off the extremity of a long bone, and to introduce a red-hot wire into the medullary cavity, ſo as to diſorganize the part completely. Soon after the perioſteum ſwells, becomes inflamed, and extremely ſenſible to the touch. The inflammation diſappears, and the ſenſibility is gradually rendered leſs acute. The internal layers of the membrane receive a depoſition of gelatine, and thus a cartilaginous ſheath is formed including the dead bone. After a certain time, of which the length may vary from many cauſes, phoſphat of lime is depoſited, and converts the cartilaginous into a bony ſheath. The inner bone is now a dead body ſurrounded on all ſides by a living one. Bichat, Anatomie Generale, tom. ii.

Medullary *Sarcoma*, in *Surgery*, a name given by Mr. Abernethy to a kind of ſarcomatous ſwelling, the conſiſtence of which reſembles that of the medullary ſubſtance of the brain. It is ſuppoſed by ſome to be a ſpecies of fungus hæmatodes. See Fungus and Tumour.

MEDUMACK, in *Geography*, a river of America, in the diſtrict of Maine, which runs into the ſea, N. lat. 44°. W. long. 69° 15′.

MEDUNA, a town of Italy, in the country of Friuli; 12 miles W. of Concordia.

MEDUNCOCK, a plantation of America, in Lincoln county, Maine; 40 miles E.S.E. of Wiſcaſſet, containing 380 inhabitants.

MEDUS, or Medinus, a name given by the writers of the middle ages to a ſtone brought from Media, of which they ſay there were two kinds, the one black, and the other green. They attribute many ſtrange virtues to theſe ſtones; the black they ſay was a fatal poiſon when taken inwardly, but that if wetted with milk, and rubbed upon the ſkin of a woman with child, it cauſed her to bring forth a boy. This ſeems to be only a falſe hiſtory of the *medea* of Pliny.

MEDUSA, in *Botany*, is a name beſtowed on this genus by Loureiro, from the long curling hairs of its capſule reſembling the ſnakes which are fabled to have covered the head of Meduſa. This name however is untenable, from its having been previouſly applied to deſignate a genus of *Vermes*. We are only acquainted with this plant as it occurs in Loureiro, and being unable to refer it to any other genus, we muſt be content to give that author's account of it. —Loureir. Cochinch. 406.—Claſs and order, *Monadelphia Polyandria*. Nat. Ord. . . . . . .

Gen. Ch. *Cal.* Perianth inferior, permanent, of five, ovate, hairy, incurved, ſpreading leaves. *Cor.* Petals five, ovate-oblong, curved, inflexed, afterwards reflexed towards the top, longer than the calyx. *Stam.* Filaments five, thread-ſhaped, united at the baſe into a tube, equal in length to the corolla; anthers incumbent. *Piſt.* Germen ſuperior, nearly round; ſtyle awl ſhaped, hairy, the ſame length as the ſtamens; ſtigma ſimple. *Peric.* Capſule ovate, three-lobed, covered with numerous, long, twiſted hairs, of one cell and three valves. *Seeds* ſix, roundiſh.

Eſſ. Ch. Monogynous. Calyx of five leaves. Petals five. Capſule with one cell, three valves, and ſix ſeeds.

1. M. *anguifera.* Snake-bearing Meduſa. Cay chôm chôm dât, of the Cochin-Chineſe. *Loureiro.*—A *tree* of middling ſize, with aſcending *branches.* *Leaves* alternate, ovate-oblong, ſerrated, pointed, ſmooth. *Flowers* red, not many on a ſtalk. *Capſule* hairy, opening in three lobes, which expand horizontally.

Medusa, in *Natural Hiſtory,* a genus of the Vermes, Molluſca claſs and order, of which the generic character is, Body gelatinous, orbicular, and generally flat underneath; the mouth central, beneath.

The animals of this genus have been commonly denominated "ſea-nettles," from the opinion that the larger ſpecies, when touched, excite a tingling ſenſation, and a ſlight redneſs of the ſkin: they are ſuppoſed to conſtitute the chief food of cetaceous fiſh; and moſt of them ſhine with great ſplendour in the water. The form of their body, while at reſt, is that of the ſegment of a ſphere, of which the convex ſurface is ſmooth, and the flat part provided with ſeveral tentacula. The body is tranſparent, and ſo gelatinous, that it is reduced almoſt to nothing by evaporation, when left on the ſhore. Several coloured lines may be ſeen within, but there is nothing that would lead one to think there is a circulation going on. The lines, which are more numerous towards the borders, ſeem to be appendages of the alimentary cavity. Theſe animals ſwim well, and appear to perform that motion by rendering their body more or leſs convex, and thus ſtriking the water. When left on the ſhore they are motionleſs, and look more like flat cakes of jelly, than living animals. There are about forty-four ſpecies diſtributed into two ſections, *viz.* A. Body with ciliate ribs: and B. Thoſe that have a ſmooth body. Many of the ſpecies are to be found in the ſeas about our own country, and will be marked as ſuch with aſteriſks.

A. *Body with ciliate Ribs.*

Species.

Infundibulum. The ſpecific character of this is, body ovate, with nine ciliate ribs. It inhabits the Indian, Mediterranean, and North ſeas; is about three inches and a half long. The body is obtuſely eight-angled, hollow, tranſparent, open at the larger extremity, and of a firm gelatinous ſubſtance. It contracts and expands with great facility: ribs purpliſh, and furniſhed with a ſingle row of ſhort and ſlender fibres.

Pileus. The body of this ſpecies is globular with ciliate ribs, and two ciliate cirri. It is found in the Mediterranean ſeas.

Cucumis. This is oblong with eight ciliate ribs, with cirri. It is found in the Greenland ſeas, and moves very ſlowly by means of the fibres on the ribs: when touched it contracts itſelf into the form of an apple. The body is white mixed with blue, and covered with irregular red ſpots: it has two apertures, terminal meeting in the oblong middle cavity. It probably derives its name from its ſhape and appearance.

Ovum. Ovate, with eight ciliate ribs and two pair of cirri, one pair of which is very long. Inhabits the Green-

land

land ſeas, and reſembles a hat, ſeldom larger than a pigeon's egg. The body is lucid and exceedingly fragile; the fragments, while alive, are blue.

B. *Body ſmooth.*

Species.

Porpita. The body of this ſpecies is flat above, beneath it is a little convex, grooved, and villous. It is found in India.

* Cruciata. This ſpecies has a body marked with a milk-white croſs. It inhabits the European ſeas. It has the appearance of a tranſparent colourleſs jelly; the body is ſurrounded at the margin with very fine fibres: the croſs is marked with a brown ſpot on each arm. It is luminous when under ſun-ſhine.

Hysocella. The body is convex, having ſixteen rays, and four united tentacula beneath. It is found in the ſea round Portugal. The body above is whitiſh, the rays compoſed of extremely minute reddiſh-brown dots; beneath it is concave; the tentacula are longer than the body, lanceolate, and marked with reddiſh ſtriæ.

* Æquorea. This is a flattiſh ſpecies, with a villous inflected tentaculate margin. It is extremely ſimple, ſoft, and fringed at the margin with white.

* Aurita. Convex above, with an inflected fringed margin; beneath with four arched cavities near the centre. It is frequently found floating on the ſurface of the ſea; is from two to four inches in diameter. When the ſun ſhines upon the animals of this ſpecies, they reflect a beautiful ſplendour.

* Capillata. The body is convex, with ſixteen indentations round the margin, and numerous ſlender filaments beneath. It inhabits the ocean, and is about eight inches in diameter. The body is deſcribed as whitiſh, ſemi-pellucid, fragile; above convex, beneath flat with a rough circle; within this there are eight pair of rays; and a number of curled fibres and appendages from the centre: the margin is divided into eight portions, each of which is emarginated.

* Pilearis. This has a capitate diſk, with eight ſmall holes on the border: beneath it is arched and hairy. The body has an irregular reflected margin.

Marsupialis This is found in the Mediterranean; is ſemi-oval with four tentacula on the margin, and reſembles a purſe.

Hemisphærica. This, as its name denotes, is hemiſpherical, with four tranſverſe ribs beneath, and marginal tentacula and globules: the margin is entire: is not a quarter of an inch in diameter, and is found in the European ſeas.

Pelagica. Hemiſpherical-concave, with a crenate incurved margin and eight tentacula. It is found in the American and Atlantic ſeas.

Noctiluca. This ſpecies is depreſſed, with reddiſh-brown warts and dots: margin with eight red tentacula.

* Fusca. The body of this has ſixteen brown rays and a brown circle in the middle; the circumference is edged with alternate crooked fangs and oval tubercles. It inhabits the coaſt of Cornwall. The tentacula are four, lacerated, and a little exceeding the body.

* Purpura. The body of this ſpecies is decorated with pale purple rays, and a light purple croſs in the centre, between each bar of which is a deep purple horſe-ſhoe-ſhaped mark.

* Tuberculata. With fifteen brown rays meeting at the centre, and ſmall oval tubercles round the margin; it has four tentacula plain, and much longer than the body. It inhabits the coaſt of Cornwall.

* Undulata. This derives its name from its undulate margin; it has fangs on the projecting parts; beneath it has four orifices, between which is a ſtem divided into eight ragged tentacula. It is found on the coaſt of Cornwall.

* Lunulata. The margin is tuberculate; beneath in the centre are four conic appendages forming a croſs, with ſeveral others, like ſerrate leaves, ſurrounding it. The tentacula are eight, not longer than the margin, and between each is a ſemi-lunar aperture. It inhabits the coaſt of Cornwall.

Nuda. Orbicular, blue, without creſt; the tentacula of the diſk are naked, with three rows of glands. It is found in the Mediterranean, and is never an inch in diameter. The body has a whitiſh diſk above, and radiate with concentric ſtriæ, the margin and border blue; the tentacula are filiform and blueiſh-hyaline.

Velelia. This alſo is orbicular, blue, with an oblique ſimple creſt or membrane, and numerous tentacula beneath. It inhabits the Atlantic and Mediterranean ſeas. The body is flat, thin oval, and marked with numerous tentacula beneath.

Spirans. Oval, blue, with oblique divided creſt or veil, and numerous tentacula beneath. It is about two inches long, and inhabits the Mediterranean. Body thin, convex, and terminating in a whitiſh central knob above, blue with a brown border; creſt two-parted and ſtriate; the tentacula are filiform.

Pulmo. Hemiſpherical-concave, with a fringed border; beneath ſtriate, the ſtem with four openings and eight arms. It inhabits the Tuſcan ſea. This has been very minutely deſcribed in the following terms:

" *Body* gelatinous, pellucid, tough, cryſtalline. The *head* is large, hemiſpherical, concave beneath, and marked with numerous ſtriæ, croſſed by ſixteen diſtant ligaments, each emitting a ſhort branch on both ſides. *Border* fringed with numerous roundiſh ſcallops. *Stem* large, thick, ſquare, with four ſemi-oval openings, each of which has a large lobe above, and a ſmaller beneath. Eight *branches* or *arms* proceeding from the lower part of the ſtem, ſub-cylindric, pendent, and wrinkled behind; beſides theſe, there are ſixteen ſubtrigonal appendages riſing from the beginning of each branch, bifid in front, and terminated on the upper ſide by a flat wrinkled ſurface; the branches end in as many ſub-pyramidical branchiæ, the two exterior ſides of which are prominent, and ending in a thickly wrinkled ſurface: theſe are terminated by eight oblong ſub-triangular thick pendent bodies, ending in three flat acute membranaceous pieces. Within the openings is a flexuous ſtriate blueiſh-yellow band."

Tyrrhena. This, as its name imports, is found in the Tuſcan ſea. It is convex; the margin crenate, and furniſhed with very long fibres or threads; beneath are four tentacula. The body is ſmooth, tender, hyaline, ſpotted with red; beneath are four cavities, each marked with a red band.

Tubercularis. The diſk of this is prominent; the margin is eight times divided and ſtriate beneath; it has eight tubercles. It is found in the Tuſcan ſea. The body is hyaline, and it is often two pounds weight; beneath fulvous, with innumerable curved fibres; tubercles blueiſh-white, ending in two ſtems, terminated by a pellucid whitiſh membrane, which is flaccid and blue or white at the tip.

Utriculus. This ſpecies is bottle-ſhaped, with a very long

long granular central tentaculum beneath; margin with numerous blue tentacula tipt with white. Inhabits the ocean; is hyaline, with about thirty marginal cirri.

Caravella. Body ovate, with very long central tentacula beneath, and a crenulate veil above. It is found in the Atlantic, and inflames the hand by its touch. The body is thin, fmooth, fhining, blueifh, hyaline, and tapering on each fide; the creft runs through the whole length of the back; it is femi-lunar, compreffed, furrowed with branched grooves, and marked with rofy veins; tentacula jointed, blue, fragile, and intermixed with fhorter tubercles.

Umbella. Tentacula of the difk naked, of the margin glandular; margin membranaceous, crenate. Inhabits the Mediterranean and Indian feas. The body is rigid, depreffed, with radiate grooves above; beneath with a clavate trunk in the middle, furrounded with fhort clavate tubes; tentacula jointed with three rows of glands.

Dimorpha. Back eminent; beneath a minute crofs furrounded with five apertures; the margin is ciliate. It is found in the North feas. The body, when expanded, is orbicular, with a fquare inflected margin; beneath it is concave; the back is divided into four parts by radiate grooves, with an elevated central crofs and white fibres.

Campanula. The difk is gibbous; the border wide and ciliate; beneath is a hairy crofs. It inhabits the Greenland feas. The body is conic-orbicular, beneath hollow and fnowy; the fringe of the margin and crofs yellow; the latter is often white.

Digitata. Hyaline, with a piftil beneath in the centre; margin ciliate. An inhabitant of the Greenland feas. It leaps with its margin bent in. Body very minute, conic, ftriate; fringe yellow or white, and hooked within; piftil ending in a yellow or white pencil.

Frondosa. Margin of the difk varied with white opaque fpots; it has eight tentacula, is dichotomous, and is befet with white pedunculate warts terminating in tufts. It is fmall, and found in the Archipelago. The body is flattifh, a little convex above; the border is membranaceous, and fringed with white fafciculi; beneath is a villous nucleus, which in the leffer ones is eight-angled, and in the larger ones ten-angled.

Tetrastyla. This is hemifpherical, without tentacula; furnifhed with four marginal tubes united into a prifm. It is found in the Red fea, and is about a fpan and a half acrofs. Body hyaline, rather rigid; the tubes of the margin are linear, three inches long, ftraight and flat.

Octostyla. Hemifpherical, without marginal tentacula; beneath is a four-folded column, with eight many-cleft lobes at the tip, and fixteen lateral appendages. This is likewife found in the Red fea. The body is of a blueifh-hyaline, and is a full foot in diameter; the column beneath is about an inch and a half long.

Andromeda. Hemifpherical, without marginal arms; beneath there are eight round ramified foliaceous arms. An inhabitant of the Red fea. The body is tranfparent, of a pale yellowifh-brown or blueifh colour, with white rays and an entire margin; in the middle is a fmall black crofs; the arms are white, and a little thicker than a goofe-quill at the infertion.

Corona. Hemifpherical, without marginal tentacula; beneath there are eight cultrate arms, toothed each fide below. It inhabits the Red fea. Body reddifh-hyaline; it is about four inches acrofs, with a blue crofs in the middle; the arms beneath are broad, and two-lobed at the tip.

Perseæ. Hemifpherical, hyaline, with an opaque white ring within, four times interrupted; there are no marginal tentacula. It is found in the Mediterranean. The body is about two inches wide, with a very prominent margin; it has four arms, fub-lanceolate, about an inch long, and undulate at the margin.

Cephea. Hemifpherical, tuberculate, reddifh-brown; beneath are eight arms villous at their extremities, and nine long filiform tentacula. It inhabits the Red fea. The body is pellucid, with eight paler rays; arms blueifh, with black extremities; the tentacula are pointed.

Proboscidalis. Hemifpherical, with a long probofcis in the middle beneath, and fix marginal tentacula. This fpecies inhabits the Mediterranean. The body is hyaline, two inches and a half broad, with a prominent equal margin; probofcis fub-flexile, and truncate at the tip, with a fringed folded verfatile membrane.

Mollicina. Depreffed, with twelve lateral apertures and tentacula. An inhabitant of the Mediterranean. The body is about an inch and a half in diameter, hyaline; the margin is prominent, with twelve plates.

Pileata. Ovate-campanulate, with a hyaline globe above; within is an oblong red nucleus; the margin has numerous tentacula that are yellow at the bafe. Inhabits the Mediterranean. The body is an inch and half high; the margin a little contracted.

Crucigera. Hemifpherical, with a reddifh crofs as wide as the body; the body is fmall, with four very minute, white, approximate rings above; the margin is thin, prominent, varioufly flexile, and often reddifh; the tentacula are numerous, but not fo long as the body is wide.

Unguiculata. Orbiculate; above flat, with fixteen rays; the margin is crenate, with fixteen flightly incurved fangs. It is found about the fhores of Jamaica, and is the fize of a nutmeg. The body is diaphanous, blueifh, and fpotted.

For a defcription of feveral of the above fpecies, as affording an exhibition of light, and for an account of certain changes, recommended by Mr. Macartney, in the arrangement of the genera, and of the names of fome of the fpecies, we refer our readers to the article Light, *Exhibition of, by living Animals*, at the clofe of the 20th volume of this work, having, in the prefent, confined ourfelves to the Linnæan reprefentation of the genus.

Mr. (now fir Jofeph) Banks, in his paffage from Madeira to Rio de Janeiro, difcovered a new fpecies of the medufa, which, when brought aboard by the cafting net, had the appearance of metal violently heated, and emitted a white light. With thefe animals were taken fmall crabs of three different fpecies, altogether new, each of which gave as much light as the glow-worm, though the creature was not fo large by nine-tenths. Thefe luminous animals gave that appearance to the fea, which has been mentioned by many navigators, and of which various reafons have been affigned. It appeared to emit flafhes of light exactly refembling thofe of lightning, only not fo confiderable, but fo frequent, that fometimes eight or ten were vifible at the fame moment.

Medusa's *Head*, in *Botany*. See Euphorbia.

MEDUSÆ Caput, in *Natural Hiftory*, a name given by authors to the *ftella marina*, called by fome, from its various branchings, *ftella arborefcens*. Rumphius, Gefner, and many other authors, have defcribed this ftrange fifh in its recent ftate; and in the Acta Eruditorum, we have an accurate figure, and a very remarkable account of one which was found foffil, and preferved in a fingularly perfect manner in ftone.

The ftone in which it was found was of the fiffile or flaty kind; and it was fo large as to extend over a piece of this ftone of four feet in length, and between three and four in breadth. The body of the fifh, from which all the reft feem

 originally

originally to have arisen, lay at one corner of this ſtone, and the arms extended themſelves lengthways in a very diſtinct and natural manner the whole length of the ſtone; and from theſe there parted, on every ſide, other ſmaller ones; and theſe were finally divided into others more minute, in ſuch a manner as to repreſent the niceſt painting. Act. Erudit. ann. 1725, p. 377.

The ſtudy of foſſils is more improved by this ſingle ſpecimen than by thouſands of others, and by the reaſonings of almoſt as many authors. The foſſils called entrochi have always perplexed the writers on theſe ſubjects to account for: ſome having judged them a ſort of ſtony vegetables; ſome a *luſus naturæ;* and others, as different things; but in this table the whole fiſh is ſo perfectly preſerved, that there can remain not the leaſt doubt of its being really the *ſtella arboreſcens;* and in this both the figure and author's words expreſs, in the plaineſt manner poſſible, that the long arms or branches, reaching from one end to the other of the ſtone, are compoſed of a number of entrochi as it were, tied together in the ſame manner as the ſingle joints of thoſe entrochi, which we meet with, are to one another: or, in plain fact, that our entrochi, which have perplexed us ſo much to account for their origin, are in reality the fragments of the arms or branches of this fiſh. Theſe branches in this famous ſpecimen were compoſed of what we call *trochitæ*, and had many rudiments of ſmaller branches, as well as perfect ones, growing from their ſides, and would have been ſo many common entrochi, if broken off.

What was moſt remarkable in this foſſile was, however, the ſeparating of ſmaller branches which ran entire to their ends, and there terminating in an infinite number of ſmall ramifications, all growing from one head, they formed cluſters of four or five inches in diameter, and of an inconceivable beauty, reſembling the compound flower of ſome elegant plant. The matter of the large branches, when examined, appeared to be the ſame with that of the common entrochi, that is, ſpar. The author calls it *ſelenites*, but that was a word indeterminately uſed by authors, till of late, for all plated and bright foſſils.

It is plain that this complete fiſh could have no way come into this ſtone but at the time when it was yet moiſt and ſoft: and the author calls it *novum diluvii monumentum, a new remembrancer of the deluge.*

Medusæ *Caput*, or *Meduſa's Head*, in *Ancient Mythology*, occurs frequently both on the breaſt-plates and ſhield of Minerva; in ſome of which it is the moſt beautiful, and in others the moſt ſhocking object. In ſome figures the face is repreſented as dead, but with the moſt perfect features that can be conceived; in others, her face is full of paſſion, and her eyes convulſed; and in many others, the look is altogether frightful, and formed on purpoſe to inſpire terror. The beauties and horrors of Meduſa's face are mentioned by the Roman poets. Ov. Met. iv. ver. 793. Lucan, lib. ix. ver. 680. Virg. Æn. viii. ver. 438. Spence's Polymetis, p. 61.

MEDWA, in *Geography*, a town of Nubia, on the borders of Dar-fûr; 80 miles N. of Cobbe.

MEDWAY, a river peculiarly connected with the county of Kent, England, was called by the Britons Vaga, a name deſcriptive of its ſinuous courſe and mazy wanderings. The Saxons changed this appellation to Medweg and Medwege, from which the preſent name is a corruption. This river has four principal ſources, one in Kent, two in Suſſex, and a fourth in Surrey. The latter riſes at Blechingly, and entering Kent, flows on to Eaton bridge and Penſhurſt, below which it is joined by one of the branches that riſe in Suſſex, and being augmented by various ſmaller ſtreams, proceeds through a beautiful country to Tunbridge. A little above this town the river ſeparates into ſeveral channels, the northernmoſt of which is navigable, and is again joined by the other diviſions about two miles below Tunbridge. Thence proceeding to Twyford bridge and Yalding, it receives the united waters of the two remaining principal branches; one of which flows from Waterdown foreſt in Suſſex, and is ſwelled by the Bewle and Theyſe rivulets; and the other of which riſes at Goldwell, near Great Chart, in Kent; this alſo receives ſeveral leſſer ſtreams in its progreſs, and is increaſed by the waters of the former branch above Hunton. From Yalding, the Medway flows in a winding direction to Maidſtone, and thence in a wildly devious channel, gradually augmenting in depth and breadth, it purſues its picturesque courſe to Rocheſter. Proceeding hence towards Sheerneſs, it paſſes Chatham, Upnor caſtle, and Gillingham fort; after which it greatly increaſes in width, and ſtill preſerving its meandering character, flows onward to the Thames, which it enters between the iſles of Graine and Shepey, having firſt united its waters to thoſe of the Swale. The Medway and its numerous tributary ſtreams are calculated to overſpread a ſurface of nearly thirty ſquare miles in the very midſt of Kent. The tide flows nearly as high as Madiſtone; but at Rocheſter bridge it is ſtrong and rapid; and below that, all the way to Sheerneſs, a diſtance of about twenty miles, the bed of the river is ſo deep, and the reaches ſo convenient, that many of the largeſt line of battle ſhips are moored here, when out of commiſſion, as in a wet dock, and ride as ſafely as in any harbour of Great Britain. In the great ſtorm of 1703, the Royal Charlotte was driven on ſhore here, and loſt.

The Medway was firſt made navigable to Tunbridge about the middle of the laſt century, under the proviſions of an act of parliament, which paſſed in the year 1740; though an act had been procured for the purpoſe in the reign of Charles II. By the laſt act, the undertakers were incorporated by the ſtyle of "The Proprietors of the Navigation of the River Medway;" and were empowered to raiſe 30,000*l.* to complete the work, in ſhares of 100*l.* each. The trade on this river is very great, and includes a vaſt variety of articles, many of them of the very firſt neceſſity, and which, before the navigation was completed, could only be obtained by a circuitous land-carriage. The river is plentifully ſtored with fiſh of various ſpecies; and was in former times much celebrated for its ſalmon and ſturgeon; the latter, in particular, were ſo abundant, that a conſiderable part of the revenues of the biſhops of Rocheſter were derived from a duty levied on their ſale. They have now in a great meaſure left the river, but are ſtill occaſionally taken of conſiderable bulk. On the Medway, and in the ſeveral creeks and waters belonging to it, within the juriſdiction of the corporation of Rocheſter, is an oyſter-fiſhery; and the mayor and citizens hold a court every year, called the Admiralty court, for regulating this fiſhery, and preventing abuſes in it. The powers of this court have been eſtabliſhed and enforced by two acts of parliament. Haſted's Hiſtory and Antiquities of Kent, 12 vols. 8vo. Beauties of England and Wales, vol. vii. by E. W. Brayley. Ireland's Pictureſque Views on the River Medway, 8vo.

Medway, a poſt-town of America, in Norfolk county, Maſſachuſetts, bounded E. and S. by Charles river, which ſeparates it from Medfield; it has two pariſhes of Congregationaliſts, and contains 1050 inhabitants; 25 miles S.W. of Boſton.

Medway, or *Midway*, a ſettlement in Liberty county, Georgia, formed by emigrants from Dorcheſter, in South Carolina, about the year 1780; 30 miles S. of Savannah.

MEDWI, a town of Sweden, in East Gothland, near the Wetter lake, much frequented on account of a celebrated mineral spring.

MEDZIBOZ, a town of Poland, in Volhynia; 20 miles S. of Constantinow.

MEDZIRON, a town of Persia, in the province of Khorasan; 60 miles E. of Meschud.

MEEADAY, or MEFOHEOUNG-YAY. See CROCODILE *Town*.

MEEKNESS, in *Ethics*, is a virtue which consists in bearing affronts, reproaches, and injuries, with a due composure of mind. Its opposite vice is *revenge*.

MEELAH, in *Geography*, a town of Algiers, in the province of Constantina, supposed to be the Milevum of the ancients, built in the midst of interspersed vallies and mountains, surrounded with gardens, and abundantly supplied with fountains; one of which bubbles up in the centre of the city, and is received into a large square basin of Roman workmanship. Its pomegranates are delicious, and it supplies Constantina with herbs and fruit; its apples are also so good, that the name of the town has been derived from that fruit; 13 miles N.W. of Constantina.

MEEN, ST., a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Montfort. The place contains 806, and the canton 9905 inhabitants, on a territory of 202½ kiliometres, in 9 communes.

MEENAH EL DSAHAB, a sea-port town of Arabia Petræa, situated on the E. coast of the gulf of Accaba, in the N. part of the Red sea, with a spacious harbour, anciently "Esion-geber;" 50 miles S. of Ailah.

MEENDOR, a town of Hindoostan, in the circar of Condapilly; 18 miles W. of Masulipatam.

MEENEES, a small island in the Sooloo Archipelago. N. lat. 6° 32′. E. long. 121° 35′.

MEENKOOT, a town of Bengal; 14 miles N. of Moorshedabad.

MEER, JOHN VANDER, in *Biography*. There were three painters who bore this name. One was devoted to the study of sea-pieces, but he sometimes painted battles by land, and executed them with very considerable skill. Another was an historical and portrait-painter; but he who best deserves renown, was a disciple of Nicholas Berchem, and succeeded admirably in imitating the style of that master. The subjects he chose were generally rather of a more confined nature than Berchem's, but they are touched with nearly equal clearness and spirit; with more softness and delicacy in their effects. He is known by the name of De Jonghe, or the Young, to distinguish him from the ship-painter, who was called the Old Vander-Meer. De Jonghe died in 1688.

MEER, in *Mining*, a space containing twenty-nine yards in length in any vein.

MEER-*stake*, is a pin of wood drove into the superficies of the earth, to shew the extent or end of a meer of ground.

MEER-*swiin*, in *Ichthyology*, a name given by some to a sea-fish, more usually known by the name of *capriscus*; which see.

MEERBECK, or MELBECK, in *Geography*, a town of France, in the department of the Lys, on a small river which runs into the Mandel; eight miles N. of Courtray.

MEERCASERAI, a town of Bengal, in the province of Chittigong; 31 miles N.W of Islamabad. N. lat. 22° 47′. E. long. 91° 42′.

MEERGUNGE, a town of Bengal; five miles S.E. of Mahmudpour.—Also, a town of Hindoostan, in Benares; 20 miles S.S.W. of Jionpour.—Also, a town of Hindoostan, in Oude; 44 miles E. of Fyzabad.

MEERGUR, a town of Bengal; four miles N. of Dinagepour.

MEERHOLZ, a town of Germany, seated on the Kinzig, giving name to a branch of the house of Isenburg, called Isenburg-Meerholz; 17 miles E. of Frankfort on the Maine.

MEERJAPOUR, a town of Bengal; six miles S. of Nogong.

MEERJASERRA, a town of Bengal; 25 miles N. of Mauldah.

MEERJEE, or MEERZAW, a town of Hindoostan, in Canara, on the coast; 10 miles N. of Onore. N. lat. 14° 28′. E. long. 72° 10′.

MEEROAT, a town of Candahar; 45 miles W. of Ghizni.

MEERPOUR, a town of Bengal; 11 miles S. of Calcutta.

MEERSCHAUM, Werner, *Ecume de Mer*, Broch., and *Keffekil*, Kirwan, in *Mineralogy*, a substance of yellowish-white colour, which occurs in mass, of fine-grained structure, earthy, passing into flat conchoidal, or small slaty, with indeterminately angular, and moderately sharp-edged fragments. This mineral is opaque, soft, easily frangible, acquires a polish by friction, and is unctuous to the touch. Its specific gravity is 1.6. In acids it may be partly dissolved without effervescence, and cannot be fused without addition by the blowpipe. The analyses of Wiegleb and Klaproth give the following results, in which there is a difference, owing to Klaproth's having analysed the fresh earth, and Wiegleb's having examined that which was formed into a tobacco pipe, and consequently baked, and deprived of its water and carbonic acid.

	Wiegleb.	Klaproth.	
Silex -	54.16	50.5	41
Magnesia	51.66	17.25	18.25
Lime -	-	0.5	0.5
Water -	-	25.	39.0
Carbonic acid	-	5.	
	105.82	98.25	98.75

For the uses to which this substance is applied among the Turks, see KEFFEKIL. This latter name is derived from Kaffa, a town of the Crimea, where it is shipped for Constantinople. It is also found in Natolia, and in the islands of Samos and Negropont. When dug from its thin beds, it is soft, and hardens by being exposed to the air.

A similar substance has been discovered by Fabbroni at Castel del Piano, near Sienna. This consists of 55 parts of silex, 25 of magnesia, 12 of alumine, 3 of lime, and 0.1 of oxyd of iron: and has been formed into bricks which float in the water. This manufacture revives one of the lost arts recorded by Strabo and Pliny.

MEERSSEN, in *Geography*, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Maestricht. The place contains 1149, and the canton 11,530 inhabitants, on a territory of 115 kiliometres, in 16 communes.

MEERTA, a town of Hindoostan, in the Subah of Agimere; 42 miles W. of Agimere. N. lat. 26° 23′. E. long. 74° 32′.

MEES, LES, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of of Digne; 12 miles S.W. of Digne. The place contains 2021, and the canton 6305 inhabitants, on a territory of 37½ kiliometres, in 8 communes.

MEESIA, in *Botany*, a genus of Mosses, established by Hedwig, Fund. v. 2. 97. t. 9. f. 56, 57, and named by him in memory of David Meese, author of the Flora Frisica, an 8vo. of 87 pages, with two plates, published in 1760. This botanist has also published an arrangement of plants, in Latin and Dutch, founded on their cotyledons and mode of germination; and a work on the Syngenesious class of Linnæus. Hedwig celebrates him as having first seen the stamens of the *Polytrichum*, and as being the first person who ever raised that moss from seed. *Meesia* differs from the *Bryum* of Hedwig, solely in the shortness and bluntness of the teeth of its external fringe, which are not half so long as the inner one. The author indeed, in his original species, found an auxiliary character in the reticulated structure of this inner fringe; but this differs only in degree, and that very slightly, from what is observable in every *Bryum*, nor is it found in the other *Meesiæ*. Three species are all that have been referred to this supposed genus, in the latest work of Hedwig, his *Species Muscorum;* and these have been reduced by the author of the *Flora Britannica* and others to *Bryum*. They are

1. M. *longiseta*. Hedw. Crypt. v. 1. 56. t. 21, 22. (Bryum triquetrum; Turn. Musc. Hib. 115. Engl. Bot. t. 2394. Mnium triquetrum; Linn. Sp. Pl. 1578, excluding the synonyms.)—Stem subdivided. Branches simple, erect. Leaves spreading in three rows, ovato-lanceolate, sharp-pointed, finely serrated. Capsule slender pear-shaped, oblique and incurved. Lid conical.—This fine moss, distinguished from all others by the length of its *fruit-stalks*, which extends to three or four inches, is found in bogs in Sweden, Switzerland, and, since the publication of Fl. Brit., in Ireland. Hedwig erroneously describes the *leaves* as entire, notwithstanding the elaborate detail of the two folio plates which he has devoted to this species.

2. M. *uliginosa*. Hedw. Crypt. v. 1. 1. t. 1, 2. (Bryum trichodes; Sm. Fl. Brit. 1350. Engl. Bot. t. 1517.)—Native of bogs in Germany and Scotland. Hedwig says it is common on alpine calcareous rocks in Austria.

3. M. *dealbata*. Hedw. Sp. Musc. 174. t. 41. f. 6—9. (Bryum dealbatum; Sm. Fl. Brit. 1350. Engl. Bot. t. 1571.)—Native of Sweden and Scotland; as well as of St. Faith's bogs, near Norwich. The *leaves* are of a singularly whitish green, finely reticulated.

These two last species are described by the late Mr. Wood, in our article BRYUM, n. 4 and 5. The first was omitted there, not being known at that time as a British plant.

MEETKA, in *Geography*, a country of Africa, W. of Bergoo.

MEFLESS, a town of Bohemia, in the circle of Konigingratz; 14 miles N.E. of Konigingratz.

MEGADOMESTICUS. See DOMESTIC.

MEGÆRA, in *Mythology*, one of the three furies. She is represented with serpents on her head, and two distinguished ones over her forehead, as her sisters have, and, like them, with torches. She is not mentioned so frequently by the Roman poets as the others are. Virgil gives us a descriptive picture of her, where he is speaking of the punishment of the Lapithæ; who were said to be always placed round a table very richly and plentifully set out, with a loose piece of rock hanging over their heads, as just ready to fall; and this fury attending close by, to watch and menace them, the moment they endeavoured to taste any one of the tempting things set before them. En. vi. ver. 607.

MEGAIZEL, in *Geography*, a town of Egypt; six miles N. of Rosetta.

MEGALA, a town of Tunis; 3 miles N.E. of Spaitla.

MEGALARTIA, Μεγαλαρτια, in *Antiquity*, a festival in honour of Ceres, being the same with Thesmophoria.

MEGALASCLEPIA, Μεγαλασκληπεια, a festival in honour of Æsculapius. See ASCLEPIA.

MAGALENSIA, or MEGALESIA, solemn feasts celebrated among the Romans on the twelfth of April, in honour of the great mother of the gods, that is, Cybele or Rhea: wherein were sports or combats held before the temple of that goddess.

They were called *megalensia*, from the Greek μεγαλη, *great*, Cybele being accounted the great goddess.

MEGALONISI, in *Geography*, a small island in the Mediterranean, near the coast of the Morea; two miles E. of Leucadia.

MEGALOPOLIS, in *Ancient Geography*, now *Leontari*, a large city, as its name imports, in the southern part of Arcadia, upon the river Helisson. Pausanias observes, that it was the most modern of the cities of Arcadia, if we except those which had been renewed by Roman colonies, after the victory of Octavius over Antony. It owed its foundation to the counsels and activity of Epaminondas, who in the year 365 B.C., being desirous of keeping the Lacedæmonians in that state of subjection to which they were reduced, induced the Arcadians to establish this city, and to settle in it a numerous colony, collected from different cities, so that it might serve as a fortress and a bulwark against Sparta. To favour them in this enterprize, and to protect them in their labours, he sent them a guard of a thousand chosen men, under the command of Pammenes. The city being thus fortified and defended, the Arcadians confided in its strength and security; and on the other hand their enemies were the more desirous of attacking it. To this object they directed their whole force; but the Megalopolitans for a long time vigorously resisted them. At length, however, *viz.* in the year 224 or 225 B.C. it fell, partly by surprize, and partly by a violation of treaties, under the power of Cleomenes, king of Sparta. The greater number of the inhabitants retired to Messenia, and emboldened by the counsels and example of Philopœmen, they refused the offer made them by Cleomenes, of remaining in their own city, on condition of concurring in the Achæan league. Philopœmen, upon their return to Arcadia, encouraged them to rebuild their city, and to adorn it with temples and magnificent edifices, which restored its former splendour. It is needless to enumerate its temples and statues, and other ornaments. The most considerable monument which the southern part of Megalopolis presented, was the theatre, a building so grand and magnificent, that it even exceeded in extent and beauty all those of Greece. We learn from Polybius that, next to Athens, Megalopolis was the grandest and most splendid city of Greece.

MEGAMETER. See MICROMETER.

MEGARA, in *Ancient Geography*, the capital of the territory of the Megarians, which has been commonly comprised in Attica, bounded eastward by mountains, and extends westward as far as a district of the isthmus of Corinth. Megara, which had previously been called Nisa, derived its name either from Megarius, the surname of Minos, a Bœotian chief, who succeeded the king of Nisa, or from Megara, the name given to ancient temples erected in honour of Ceres, or from Megara, a supposed wife of Hercules. Under the reign of Codrus, the Peloponnesians having declared

clared war againſt the Athenians, and miſcarried in their enterprize, returned and took poſſeſſion of Megara, which they peopled with Corinthians. Beſides two citadels, this city had ſeveral magnificent ſtructures and ornaments; one was an aqueduct, diſtinguiſhed by the grandeur and beauty of its columns, conſtructed by Theagenes, tyrant of Megara; another was a ſtatue of Diana, the protectreſs; to which we may add, the ſtatues of the twelve great gods, attributed to Praxiteles; a group conſecrated to Jupiter Olympius, in which was a ſtatue of this deity, with the face of gold and ivory, and the reſt of the body of burnt earth; and upon the path that led to one of the citadels of Megara, called Caria, were a temple of Bacchus Nyctalus, another of Venus Spiſtrophia, a chapel dedicated to the Night, whence iſſued her oracles; a temple of Jupiter; two ſtatues, one of Æſculapius, and one of Hygeia, executed by Briexis, and a temple of Ceres, called the Megaron; north of the citadel, near the temple of Jupiter the Olympian, was the tomb of Alcmenes, and that of Hyllus, ſon of Hercules; a temple of Apollo and Diana, the tomb of Hippolyta, queen of the Amazons, and the tomb of Therea. Beſides theſe edifices, there were in the ſecond citadel, called the citadel of Alcathous, a tomb of Megareus, and a temple of Minerva, with her ſtatue, the body of which was gilt, and the face, feet, and hands were of ivory, &c. &c. See Pauſanias in Attica, c. 39—44.

Megara was alſo the name of a town on the eaſtern coaſt of Sicily, on the gulf of Megara, otherwiſe called Xiphonius, N. of Syracuſe. This city, which is ſaid to have been built here by the Greeks of Megara, the city of Achaia, (ſee the preceding article,) gave name to the mountain, called "Hybla Megara." This colony, 100 years after its eſtabliſhment, founded Salinus, which was deſtroyed by Marcellus when he beſieged Syracuſe. The ruins of Megara are now ſcarcely diſcernible.

Megara, a town of Illyria.—Alſo, a town of Pontus.—Alſo, a town of Aſia, in Syria, dependent upon Apamæa.—And alſo, a town of Greece, in the Peloponneſus.

Megara, in *Geography*, a town of European Turkey, in the province of Livadia, on the coaſt of the gulf of Engia, once the capital of a republic, now very much reduced; 26 miles W. of Athens.

MEGARBE, a town of Nubia; 9 miles W.S.W. of Maſuah.

MEGARIS, or the Megaride, in *Ancient Geography*, a country of Attica. See Megara *ſupra*.

Megaris, a town of Italy, in Campania, placed by Pliny between Naples and Pauſilipo.

MEGATHERIUM, in *Natural Hiſtory*, a genus of the claſs Mammalia, order Bruta. This is generally known by the name of *mammoth*. It has a near reſemblance to the elephant, but its having never been found alive, nor with its organs in a perfect ſtate after death, its generic character cannot be accurately aſcertained. By ſome accounts from St. Peterſburg, it is ſuppoſed that the animal ſtill exiſts in a living ſtate, though it has hitherto eſcaped the reſearches of modern naturaliſts. Its reſidence appears to have been confined to a line in the northern hemiſphere, extending from Siberia to the banks of the Ohio, and the common name of mammoth was firſt given to the ſkeleton when dug from the earth by a Siberian peaſant. The following is the beſt account we have of this animal: it was received from St. Peterſburg, and relates to a ſpecimen found, though not alive, yet in a complete and almoſt perfect ſtate of preſervation. A Tungooſe chief, in the ſummer of 1799, when the fiſhing in the river Lena was over, repaired, according to annual cuſtom, to the ſea-ſide. Leaving his family in their huts, he coaſted along the ſhore in queſt of the tuſks of the mammoth, when he accidentally perceived, in the midſt of a rock of ice, a large ſhapeleſs block, not at all reſembling the logs of drift wood commonly found there. He climbed the rock, and examined it all round, but could not aſcertain what it was. The next year he returned, and found the carcaſe of a *trichecus roſmarus*, and obſerved that the maſs which he had ſeen before was freer from ice, but that there were two ſimilar pieces by the ſide of it. Theſe proved to be the feet of the mammoth. In 1801, the ſide of the animal and one of its tuſks appearing very diſtinctly, he acquainted his wife and ſome of his friends with what he had found. An alarm was inſtantly ſpread: the aged people affirmed that a ſimilar monſter had been ſeen once before, and that the whole family of the perſon who diſcovered it ſoon became extinct. At firſt the chief, terrified at the report, abandoned his prize, fell ſick, and was brought nearly to the grave; but on his recovery, he was more reſolute, and was determined not to relinquiſh the expectation of the profit he might make of the tuſks. It was not, however, till the fifth year, that the ice had melted ſufficiently to diſengage the mammoth, when it fell over on its ſide on a bank of ſand. The Tungooſe was quite ſatisfied to take away the tuſks, which he bartered for goods to the value of 50 rubles, or rather more than 11*l.* Being ſatisfied with the prize, the carcaſe was left to be devoured by the bears, wolves, and foxes. Previouſly to this he had made a rude drawing of it, which repreſented it as having pointed ears, ſmall eyes, horſe's hoofs, and a briſtly mane extending along the whole back. In 1806, Mr. Michael Adams, of Peterſburg, being at Yakoutſk, heard of the circumſtance, and proceeded to the ſpot, in order to inveſtigate every thing relating to it. Before his arrival, the ſkeleton was ſtripped of its fleſh, but was itſelf entire, with the exception of one fore-foot. The vertebræ, one of the ſhoulder-blades, the pelvis, and the remaining three extremities, were held firmly together by the ligaments of the joints, and by ſtrips of ſkin and fleſh. It received ſome damage in the removal to Peterſburg, a diſtance of almoſt 7000 miles. The ears, however, were preſerved, and the pupil of the left eye was perfectly diſtinguiſhable. From other parts it proved to be a male, with a long mane, but had neither tail nor trunk. From the ſtructure of the os coccygis, Mr. Adams did not entertain a doubt that it had a ſhort thick tail, and he thinks it muſt have had a proboſcis. The ſkin was of a deepiſh grey colour, and covered with reddiſh hair and black briſtles. The head weighed 460lb.; the two horns weigh 400lb.: the entire animal was 10½ feet high, and full ſixteen feet long. Mr. Adams has ſeen the tuſks, and ſays they are ſo curved as to form three-fourths of a circle. They are curved in the direction oppoſite to thoſe of the elephant, bending towards the body of the animal. In 1801, Mr. William Peale, proprietor of the muſæum at Philadelphia, ſucceeded in obtaining a ſkeleton ſo nearly complete, that, by a few additions only, he rendered it, as it were, perfect. This ſkeleton was brought to London, and exhibited eight or nine years ago.

The generic name of *Megatherium* was firſt given to it by M. Cuvier, who has accurately examined the ſkeleton; and to the generic name he added the trivial one of *Americanum*. In Dr. Shaw's Zoology it is deſcribed as a ſpecies of the Manis genus, and is denominated Manis megatherium. According to Cuvier, the ſkeleton which he ſaw at Madrid was twelve feet long, and about ſix in height. The ſpine is compoſed of ſeven vertical, ſixteen dorſal, and four lumbar vertebræ. It has ſixteen ribs; the ſacrum is ſhort, the oſſa ilia very broad. The thigh-bones are exceſſively thick, and the leg-bones ſtill more ſo in proportion. The entire ſole of the

the foot bore on the ground in the act of walking. The shoulder-blade is much broader than long: the fore-limbs are longer than the hind. The head is the greatest singularity of the skeleton. The occiput is elongated and flattened, but is convex above the eyes. The two jaws form a considerable projection, but without cutting teeth, all grinders, with a flat crown, and grooved across.

This quadruped, in its character, differs from all known animals: and each of its bones, considered apart, also differs from the corresponding bones of all known animals. This results from a comparison of the skeleton with that of other animals, for none of the animals which approach it in bulk, have either pointed claws, or a similarly formed head, shoulder-blades, clavicle, pelvis, or limbs. "As to its place in the system of quadrupeds," says the French naturalist, "it is perfectly marked by the sole inspection of the ordinary indicatory characters, that is, the claws and teeth. These shew that it must be classed in the family of unguiculated quadrupeds, destitute of cutting teeth, and in fact it has striking relations with those animals in all parts of its body. This family is composed of the dasypus, bradypus, manis, myrmecophagus, and Cape ant-eater, or oryćteropus. The thickness of the branches of the lower jaw, surpassing even that of the elephant, seems to prove that this vast animal was not content with leaves, but, like the elephant and rhinoceros, broke on the ground the branches themselves; its close and flat-crowned teeth appearing very proper for that purpose." Cuvier thinks there are indications that this animal had a trunk, but that it must have been short, since the length of the head and neck together only equals that of the fore-legs. He places it between the bradypus and the dasypus genera, because to the shape of the head of the former it joins the teeth of the latter. It would be necessary to know particulars, of which a skeleton cannot inform us, in order to determine to which of these it approached the most. "This adds," says Cuvier, "to the numerous facts which apprize us that the animals of the ancient world were all different from those we now see on the earth, for it is scarcely probable that if this animal still existed, so remarkable a species would have hitherto escaped the researches of naturalists. It is also a new and very strong proof of the invincible laws of the subordination of characters, and the justness of the consequences deduced for the classification of organized bodies: and under both these views, it is one of the most valuable discoveries which have for a long time been made in natural history."

MEGE, in *Geography*, a town of Persia, in Farsistan; 10 miles S. of Ispahan.

MEGE'VE, a town of France, in the department of the Leman, and chief place of a canton, in the district of Bonneville. The place contains 3075, and the canton 9951 inhabitants, on a territory of 180 kiliometres, in seven communes.

MEGGIO, a town of Africa, in Fez; nine miles from the Mediterranean.

MEGHARISH Uzzur, or Acra, a town of Arabia, in the province of Hedsjas; 85 miles E.S.E. of Madian.

MEGHEM, or Megen, a town of Brabant, on the Meuse; 12 miles S. of Nimeguen.

MEGNITZESC, a town of Sclavonia; 18 miles W.S.W. of Verovitza.

MEGRA, a town of Russia, in the government of Archangel, on the E. coast of the White sea; 72 miles N. of Archangel.

MEGUNTICK, a lake of Canada, on the borders of Maine. N. lat. 45° 44'. W. long. 70° 25'.

MEHALLE' el Kebiré, a town of Egypt, capital of Garbia, the second province of the Delta, and the residence of a bey. As there is no town more considerable in the Delta, it is called Kebira the Great. It has manufactories of linen and some sal ammoniac works. A great deal of business is done there. The rivers which surround it serve for the conveyance of its merchandize through Egypt. Its environs are covered with villages, flocks, and the various productions of a fertile soil; 47 miles N. of Cairo. N. lat. 30° 50'. E. long. 31° 24'.

MEHALLEBEG, a town of Persia, in the province of Irak; 25 miles S.E. of Rai.

MEHALLET il Emir, a town of Egypt, on the Nile; six miles S.E. of Rosetta. N. lat. 30° 50'. E. long. 30° 24'.

Mehallet *il Loben*, a town of Egypt; 16 miles S. of Faoué.

Mehallet *Malek*, a town of Egypt; five miles S. of Faoué.

Mehallet *il Meshak*, a town of Egypt; five miles N.N.E. of Tineh.

MEHAMA, one of the smaller Friendly islands, in the Pacific ocean; four miles E. of Neeneeva.

ME'HE'GAN, William Alexander, in *Biography*, was born at la Salle, in the Cevennes, in the year 1721, of a family originally from Ireland, which had followed the fortunes of James II. He was prevented from adopting the profession of arms, in which his family had been distinguished, by ill health, and cultivated the belles lettres, attaching himself particularly to the study of eloquence. When Frederic V. king of Denmark founded, in the year 1751, a professorship of the French language, M. de Mèhègan composed a discourse which was pronounced at the opening of the lectures in Copenhagen. In the following year he published a work entitled "L'Origine des Guebres; ou la Réligion naturelle mise en Action," which was looked upon as breathing the spirit of modern philosophy. This was followed at distant intervals by "Considerations sur les Révolutions des Arts;" "Pièces fugitives;" "Mémoires de la Marquise de Terville;" "Lettres d'Aspasie," and in 1759 "L'Origine, le Progrès, et la Dècadence de l'Idolatrie." He died in 1766, and after that event, was published, as a posthumous work of M. Mèhègan, "Tableau de l'Histoire moderne," in three vols. 12mo. This is highly esteemed on account of the warmth and eloquence of the style, and the generally impartial and philosophical spirit by which it is animated. The history commences with the year 476, and concludes with the peace of Westphalia in 1648. "It is," says his biographer, "full of picture and portrait, upon which he sometimes throws too strong a glare of colouring; he has, however, succeeded in making his work much more interesting than abridgments usually are, and at the same time has judiciously selected the points of instruction." There is an English translation of it. In 1767 was published another posthumous work of this author, entitled "L'Histoire considerée vis-à-vis la Réligion, les Beaux-Arts, et l'Etat," in three volumes 12mo. Gen. Biog.

MEHEM, in *Geography*, a town of Hindoostan, in the subah of Delhi; 27 miles W.S.W. of Rodak.

MEHERRIN, a town of America, in North Carolina; 25 miles E. of Halifax.—Also, a river of Virginia, which runs into the Chouan, 20 miles N.W. of Hartford, in N. Carolina.

MEHINDEY, a river of Hindoostan, which runs into the gulf of Caubay, about 40 miles S. of Amedabad.

MEHITPOUR, a town of Hindoostan, in Lahore; 45 miles S.E. of Sultanpour.

MEHRIBAN, a town of Curdistan; 22 miles S.E. of Sherezur.

MEHUN, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges, situated on the Eure; seven miles N.W. of Bourges. The place contains 1267, and the canton 7064 inhabitants, on a territory of 287⅓ kiliometres, in 12 communes. Charles VII. had a palace in this town, where he resided, and starved himself to death for fear of being poisoned by his son Louis XI. N. lat. 47° 9′. E. long. 2° 18′.

Mehun, a small island in the straits of Babelmandeb. N. lat. 12° 20′.

MEHUNTPOUR, a town of Hindoostan, in the circar of Chanderee; 16 miles N.W. of Chanderee.

MEI, Girolamo, in *Biography*, a Florentine nobleman, mathematician, philosopher, and theoretical musician, who flourished in the latter end of the sixteenth century. Battista Doni, in his "Trattato secondo sopra gl'Instrumenti di Tasti," or keyed instruments, says, that in the beginning of his musical studies, his partiality for the music of the ancients was greatly increased by the perusal of the dialogue of Galilei, in which Mei had the greater part (dove il Mei ebbe la meggior parte), and still more by a treatise written by this learned personage (Mei) "De Modis Musicæ," a MS. presented to the Vatican library by Monsig. Guarengo. Op. Om. t. i. p. 324. Doni has supported this assertion by no proof; but in the Vatican library, among the queen of Sweden's MSS. there is a volume of inedited tracts and letters, written by Girolamo Mei, upon the music of the ancients, in which are discoverable, not only opinions similar to those of Galilei, but frequently the words in which they are expressed in his dialogue; particularly in a letter from Mei, dated Rome, 1572, in answer to two that he had received from Galilei, in which he seems to have been consulted concerning the usual difficulties which those have to encounter who undertake to discuss the music of the ancients. We procured a copy of this letter entire, and considerable extracts from the other writings of Mei, which indeed contain the whole substance of Galilei's dialogue, except what concerns the controversy with Zarlino relative to the musical scales and proportions of the ancients.

Mei *Misere*. See Miserere.

MEIA Sarekin, in *Geography*, a town of Asiatic Turkey, in the government of Diarbekir; 30 miles E.N.E. of Diarbekir. N. lat. 38° 5′. E. long. 39° 55′.

MEIANE, a town of Persia, in the province of Comis; 18 miles S.S.E. of Bistan.

MEIANO, a town of Italy, in the department of the Mela; 12 miles S.S.W. of Brescia.

MEIAS-Farekin, a town of Asiatic Turkey, in the province of Diarbekir; 25 miles N.E. of Diarbekir.

MEIBOMIA, in *Botany*, a genus of Heister's, named after Brandanus Meibom, professor of medicine at Helmstadt, who died in 1740, aged 62, but who is not recorded as having written any botanical work. The plant on which Heister founded his genus is *Hedysarum canadense* of Linnæus. We do not find that he has given any other character, than enumerating it among papilionaceous genera with ternate leaves; see Heist. syst. 9.

There was another professor Meibom at Helmstadt, who wrote upon beer, *de cerevisiis potibusque et ebriaminibus extra vinum aliis commentarius*, and died in 1655, aged 65. Dryandr. Bibl. Banks.

MEIBOMIAN Glands, in *Anatomy*, very small round bodies, arranged in parallel vertical lines on the inner surface of the tarsi of the eyelids, and secreting an unctuous substance, which is poured from their ducts on the ciliary edges of the palpebræ, and prevents their agglutination. See Eye.

MEIBOMIUS, John Henry, in *Biography*, a learned physician, was born at Helmstadt, in August 1590. He spent a considerable time on his travels in Italy, for the purposes of improvement in science and literature; and, having given his attention to medicine, in which he made great progress, he went ultimately to Basle, in 1619, where he was honoured with the degree of doctor of physic. On his return to his native place, his character obtained for him, in 1620, the appointment of professor of medicine from the faculty of that university; and he continued in the office about six years, when he removed to Lubeck, where he had been chosen physician to the city, and to its bishop. Here he passed the rest of his life, which terminated in May 1655, in his sixty-fifth year. In the latter period of his life, he employed himself chiefly in the investigation of medical history, and left a manuscript to his son, entitled "De Vitis Medicorum usque ad seculum xv;" but this work was never printed. The following are the whole of his published works, the two last of which appeared after his death. 1. "Hippocratis Orkos, sive Commentarius in Hippocratis jusjurandum," Lugd. Bat. 1643, 4to. 2. "De Flagrorum usu in re venerea," ibid. 1643, which was reprinted at London, Copenhagen, and Francfort. 3. "Epistola de Cynophoria, seu, Canis portatione ignominiosâ," Helmstadt, 1645. 4. "De Mithridatio et Theriaca Discursus," Lubec. 1652, 1659. 5. "Mæcenas, sive, de C. D. Mæcenatis vitâ, moribus, et gestis, Liber singularis," Lug. Bat. 1653. 6. "De Cerevisiis, Potibusque et Ebriaminibus extra Vinum aliis, Commentarius," Helmstadt, 1668, published together with the treatise of Adrian Turnebus, "De Vino;" and 7. "Aurelii Cassiodori Formula Comitis Archiatrorum," ibid. 1668; which is a commentary on the 19th epistle of the 6th book of Cassiodorus. Eloy Dict. Hist.

Meibomius, Henry, son of the preceding, was born at Lubeck, in June 1638. After having gone through various courses of study at Helmstadt, and in different Dutch universities, he travelled into Italy and France, and took his doctor's degree at Angers, in 1663. He then continued his travels into England, whence he returned to Germany. His father's name was still held in estimation at Helmstadt, and his own talents and acquirements gained him considerable respect, so that he was soon enrolled among the professors of that university; in which he held successively the chairs of medicine, poetry, and history; the last of which he retained at the time of his death, in March 1700, when he had reached his sixty-second year. Occupied as he ever was in the practice of his profession, and in his academical labours, he nevertheless found leisure to write several works, and also to superintend the publication of the writings of others. His first dissertation, "De Incubatione in Fanis Deorum, Medicinæ causâ, olim factâ," was published at Helmstadt, in 1659. It contained a history of the priest-medicine of ancient times, and of the various ceremonies, offerings, and sacrifices, instituted in different Pagan temples, in conducting this practice. He edited a treatise of Arnold de Boot, which had been published in London, in 1649, entitled "Observationes Medicæ de Affectibus omissis;" with a preface, and many valuable notes, ibid. 1664. He also published "De Vasis Palpebrarum novis, Epistola ad Joëlem Langelottum," ibid. 1666. "De Ossium contusione Disputatio," ibid. 1668; and several other small dissertations, which evinced his great knowledge of the animal economy, and its disorders. He seems to have contemplated a history of medicine, and printed, "De Medicorum Historiâ scribendâ, Epistola ad G. H. Velschium," ibid. 1669; but the difficulties

culties which he met with in investigating the medicine of the Arabians arrested his progress, and deterred him from publishing the work left him by his father. He published, however, the following: "Parentatio I. Danielis Schmidt," Dantisci, 1687. "Ad Saxonicæ Inferioris Historiam Introductio," Helmstadt, 1687. "Scriptores Rerum Germanicarum," ibid. 1688, in two vols. folio; and he edited Valentin. Hen. Vogler's "Introductio universalis in notitiam cujuscumque generis bonorum scriptorum," ibid. 1700, with additions.

Some other individuals of the family of MEIBOMIUS were professors at Helmstadt; especially *Henry*, the grandfather of the preceding Henry, who published several works; *Mark*, whose studies were entirely confined to history and the belles-lettres; and *Brandus*, who taught medicine, and published several academical dissertations, about 1730. Eloy Dict. Hist. de Med.

MEIBOMIUS, MARCUS, a writer of great erudition, particularly in the music of the ancient Greeks, was descended from a very learned family at Helmstadt, who successively practised physic in that city, with great reputation.

Marcus Meibomius was born about 1611, and in 1652 he published from the Elzevir press, in two volumes 4to. dedicated to Christina, queen of Sweden, the following work: "Antiquæ Musicæ auctores septem Græce et Latine, Marcus Meibomius restituit ac Notis explicavit. Amstel. apud Lud. Elzivirium, clↄ. lx. lii." The first volume contains:

I. Aristoxeni Harmonicorum Elementorum, libri iii.
II. Euclidis Introductio Harmonica.
III. Nichomachi Geraseni, Pythagorici, Harmonius Manuele.
IV. Alypii Introductio Musica.
V. Gaudentii, Philosophi Introductio Harmonica.
VI. Bacchii Senioris Introductio Artis Musicæ.

The second volume.

Aristidis Quintiliani de Musica, libri iii.
Martiani Capellæ de Musica, liber ix.

Meibomius, after this learned and elegant publication, was invited to the court of the queen of Sweden, which invitation he accepted.

Having, by his enthusiastic account of the music of the ancients, impressed this princess with similar ideas, the younger Bourdelot, a physician, and his rival (as a classical scholar) in the queen's favour, instigated her majesty to desire him to sing an ancient Grecian air, while Naudet, an old Frenchman, danced *à la Grec* to the sound of his voice. But the performance, instead of exciting admiration, produced loud bursts of laughter from all present; which so enraged Meibomius, that seeing the buffoon Bourdelot in the gallery among the scoffers, and having no doubt but that it was he who, with a malicious design, had persuaded her majesty to desire this performance, immediately flew thither, and exercised the pugilist's art on his face so violently, without being restrained by the presence of the queen, that he thought it necessary to quit the Swedish dominions before he could be called to an account for his rashness; and immediately went to Copenhagen, where, being well received, he fixed his residence there, and became a professor at Sora, a Danish college for the instruction of the young nobility; here too he was honoured with the title of aulic counsellor, and soon after was called to Elsineur, and advanced to the dignity of Architesorié, or president of the board of maritime taxes or customs; but neglecting the duty of his office, he was dismissed, and upon that disgrace quitted Denmark.

Soon after he settled at Amsterdam, and became professor of history in the college of that city; but refusing to give instructions to the son of a burgomaster, alleging that he was not accustomed to instruct boys in the elements of knowledge, but to finish students arrived at maturity in their studies; he was dismissed from that station.

After quitting Amsterdam, he visited France and England; then returning to Holland, he led a studious and private life at Amsterdam till 1710 or 1711, when he died at near 90 years of age.

Besides the seven Greek writers on ancient music, Meibomius published an edition of the Greek mythologists; a treatise de Fabrica Triremium; a new edition of Vitruvius, with a commentary on the *Echeia*, or harmonic vases, described book 5; correcting, for a new edition, the Hebrew bible. This daring work appeared at Amsterdam, 1698, in folio, under the title "Davidis Psalmi, et totidem sacræ scripturæ veteris Testamenti capita—restituta, &c."

The most solid and celebrated of his critical works is his edition of the seven Greek writers on ancient music, in which all subsequent writers on the subject of ancient music place implicit faith. It is from the indefatigable and learned labours of Meibomius, in his commentaries on the Greek writers in music, particularly Alypius, that we are able to fancy we can decipher the musical characters used by the ancient Greeks in their notation; which, before his time, had been so altered, corrupted, disfigured, and confounded, by the ignorance or negligence of the transcribers of ancient MSS., that they were rendered wholly unintelligible.

MEICHE, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of St. Hippolyte. The place contains 690, and the canton 7864 inhabitants, on a territory of $222\frac{1}{2}$ kiliometres, in 31 communes.

MEIDAN, a town of Persian Armenia; 100 miles N.E. of Erivan.

MEIDANS, in the *Eastern Nations*, are a sort of country-seats, where the greater people have often summer-houses, to which they retire on the three days of the week in which they do not attend the pasha's divan, and where they divert themselves with seeing their slaves ride, shoot, and throw the dart, while they are regaling with their pipe and coffee.

MEIDOBRIGA, in *Ancient Geography*, a town of Hispania, in Lusitania, S.W. of Nuba Cæsarea. It was formerly a powerful city; and its inhabitants were called Plumbarii, on account of the mines of lead which were found in its vicinity. Some traces of it have been discovered in a place called Armenha. South of this town was a chain of mountains, denominated "Mons Herminius."

MEIDON, or MEIDUN, in *Geography*, a town of Egypt, at some distance from the left bank of the Nile, near which is the most southerly of the pyramids; it is thought to occupy the scite of the ancient Nilopolis; 32 miles S. of Cairo.

MEJEDDAH, a town of Algiers, on the Shellif; five miles N.E. of Seedy-Abid.

MEJERDAH, or MAI-SEAR-DA, a sea-port town of Algiers, in the province of Tremecen, consisting of meanly-constructed cottages. From this place a great quantity of corn is exported to Europe; 42 miles W. of Tremecen. N. lat. 35° 8'. W. long. 1° 35'.

MEJERDAH, a river of Africa, formed by the union of the Sujerass and the Serrat, on the borders of Algiers; after traversing the country from W. to E. it runs into the Mediterranean at Porto Farina. It pursues a winding course through a country, which it contributes to fertilize, and in this respect, as well as by its encroachments on the sea, it resembles

resembles the Nile. This river was anciently called "Bagrada," or "Brada." See Bagrada.

MEILAN, a town of European Turkey, in Natolia; 18 miles W.N.W. of Kiangari.

MEILHAN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; six miles W.N.W. of Marmande. The place contains 2414, and the canton 9552 inhabitants, on a territory of 170 kiliometres, in 10 communes.

MEILHUYS, a town of Norway, in the government of Drontheim; 14 miles S.W. of Drontheim.

MEIMARG, a town of Grand Bucharia; 36 miles S.E. of *Bokhara*; which see.

MEIMEND, a town of Persia, in Segestan; 40 miles W. of Candahar. N. lat. 33° 5'. E. long. 65° 45'.

MEINAM, signifying the "Mother of Waters," a large river of Siam. According to Loubere, this river, when it enters the dominions of Siam, is so small that it can only convey small boats, scarcely sufficient for carrying above four or five persons. It is afterwards very much augmented, at the town of Lancocevan, by another considerable river from the north, of the same name, or rather by the reunion of a branch of the same river. Loubere's account of the smallness of the stream has been doubted, and it has been suggested, that it was only obstructed in its course by rapids or cataracts. When we advert to the regular inundations, similar to those of the Nile and Ganges, which are rivers of long course, and other circumstances, we may infer that the Meinam is of a more distant and higher origin than the mountains of Yunnan in the west of China; and that the Thibetian Alps furnish its source in that of the Nou Kian of the Lamas, supposed to be the Thaluan or river of Martaban, which has no Delta, nor any marks of so distant an origin, but is represented by Loubere and d'Anville as a short and insignificant stream. The Meinam is celebrated among the oriental rivers. Kæmpfer says, that it is very deep and rapid, always full, and larger than the Elbe. He adds, that the inhabitants suppose its source to be in the mountains, which give rise to the Ganges, and that it branches through Cambodia and Pegu; an account somewhat confirmed by the discovery of the river Anau, which connects the Meinam with the rivers of Cambodia. The inundations are in September, after the snows have melted in the northern mountains, and the rainy season has commenced. In December the waters decline, and by degrees sink to their former level. The same intelligent traveller informs us, that the water in the earth swells before the river rises; that the wells are nitrous, but the water of the Meinam, though muddy, is pleasant and salutary; that the inundations are chiefly discernible towards the centre of the kingdom, not near the sea; that the rice is reaped in boats, and the straw left in the water; that a festival is celebrated in December, when the wind begins to blow from the north, and the inundation abates. The banks of the Meinam are generally low and marshy, but thickly peopled from Yuthia to Bankok, below which are wild desarts like the Sunderbunde of the Ganges. Monkies, fire-flies, and moskitoes swarm on the fertile shores. Pinkerton.

MEINART, a town of Germany, in the county of Hohenlohe; 7 miles S.E. of Ohringen.

MEINAU, an island in the N.W. part of the lake of Constance, with a commandery of the Teutonic order; about three miles in circumference. In 1805 it was added to Baden, once so celebrated for its wine; 14 miles N. of Constance.

MEINOR. See Mainour.

MEINUNGEN, in *Geography*, a town of Germany, in the county of Henneberg, belonging to the prince of Saxe-Weimar, situated amidst mountains, on the river Werra; 21 miles N. of Schweinfurt. N. lat. 50° 37'. E. long. 10° 40'.

MEIONITE; *Hyacinthe blanche de Somma*, Romé de l'Isle; *Hyacinthine*, Delameth.

The colour of this mineral is a greyish-white.

It occurs seldom massive; generally in prismatic crystals, the primitive form of which is a rectangular prism with square bases. The principal modifications are

The rectangular four-sided prism, acuminated by four planes placed on the lateral edges.

The preceding with lateral edges truncated (*dioctaèdre*, Haüy, fig. 76.) The truncating planes are often seen on two opposite edges only.

The same, but with lateral edges bevilled, and the bevilment again truncated; the edges formed by the lateral ... acuminating planes likewise replaced by a plane, (*soustractif*, Haüy, fig. 77.)

Often one of the acuminating planes increases at the expence of the others which sometimes entirely disappear.

The crystals are small, seldom middle-sized, closely grouped together. They are splendent, with a vitreous lustre, especially when viewed in the direction of the longitudinal fracture.

Longitudinal fracture foliated, the folia parallel with the four sides of the prism; cross fracture conchoidal: the former is indicated by fissures observable in the interior.

It is semi-transparent passing into transparent.

It is hard, scratching glass.

Before the blowpipe it effervesces, and easily melts into a spongy white glass.

We are still without an analysis of this substance.

Meïonite is found at Capo di Bove, near Rome, in basalt with melilite, augite, leucite; and on Monte Somma, among the volcanic ejections of Vesuvius, with calcareous spar or granular limestone.

This mineral substance was first discovered by Romé de l'Isle, who considered it as a variety of Vesuvian; Haüy afterwards found it to be a distinct species, to which he gave the name it now bears, and which has been also adopted by Werner, who at first considered it as a variety of feldspar.

From mesotype-zeolite, with which it might be confounded at first view, the meïonite differs in not forming a jelly with nitric acid.

MEIOSIS, in *Rhetoric*, is a figure, which is a species of the hyperbole.

MEIRONNES, in *Geography*, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Barcelonnette. The place contains 554, and the canton 3252 inhabitants, on a territory of 335 kiliometres, in three communes.

MEISENHEIM, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Birkenfeld. The place contains 1730, and the canton 7512 inhabitants, in 21 communes.

MEISNER, Balthasar, in *Biography*, an eminent German Lutheran divine, was born in Saxony in the year 1587. At the age of fifteen he was sent to pursue his academical studies at the university of Wittemberg, where he took his degree of M.A., and acquired much reputation by his diligence and talents. He studied also at the universities of Strasburg, Tubingen, and Giessen; but in 1611 he returned to Wittemberg, and was appointed professor of moral philosophy, and in 1614 he was elected to the theological chair, which he filled with great success during the remainder

 of

of his life. He died in 1626, leaving behind him works that bear witness to his learning and zeal, of which we may notice "Commentarius in Hoseam:" "Meditationes Sacræ in Evangelia:" "Anthropologia Sacra," in two vols. quarto, and "Philosophia Sobria, hoc est, consideratio Questionum Philosophicarum," in three vols. quarto.

MEISSANG, in *Geography*, a town of Africa, in Kaarta; 52 miles E. of Kemmoo.

MEISSAU, a town of Austria; 34 miles N.W. of Vienna.

MEISSEN, *Margraviate of*, a principality of Saxony, founded in the 10th century, and united in 1422 to the electorate of Saxony. Its boundaries have been various at different periods.

MEISSEN, a city of Saxony, capital of the margraviate above-mentioned, situated on the Elbe, at its confluence with the Meisse, whence its name. Out of several jurisdictions that formerly belonged to this town arose the four prefecturates of Meissen, to which pertain several villages. In the centre of the old citadel, the other parts of which are in a ruined state, is the part called "Albretschsburg," in which is carried on the celebrated manufacture of the excellent Misnian porcelain. At this place is also a manufacture of cloth. The first foundation of this town was begun by king Henry I. about the year 930; 14 miles N.W. of Dresden. N. lat. 51° 19′. E. long. 13° 27′.

MEKAM ALI, a town of the Arabian Irak, on the Euphrates, opposite to Bassora.

MEKAM *ul Kidr*, a town of the Arabian Irak, on the Euphrates; 26 miles S.S.E. of Hellah.

MEKARA, a name of the Hindoo goddess *Parvati*, which see.

MEKEHOAN, in *Geography*, a town of Arabia, in the province of Oman, on the Persian gulf; 45 miles W.S.W. of Julfa.

MEKELBURG, a town of Prussia, in the province of Bartenland; 12 miles S.S.E. of Bartenstein.

MEKES, a town of Curdistan; 30 miles S.S.E. of Betlis.

MEKKIAS, signifying measure, a name given to the Nilometer, situated on an island in the front of old Cairo, about 500 yards in breadth. It is there, in front, that upon the graduations of a pillar the rise of the river is measured, and from the observations made upon it, public cryers go about the streets of Cairo, proclaiming the successive heights of the water, in which are centered all hopes of fertility and abundance. This Nilometer is said to have been built by the Arabs. The island on which it stands is called "Roudda," or gardens, because it is laid out in gardens, and inhabited only by gardeners. See NILOMETER.

MEKLAF AL ASFAT, a town of Arabia, in Yemen; 75 miles N. of Hasec.

MEKZARA, a country of Africa, on the S. side of the Niger, between Cashna and Melli.

MEL, GAUDIO, FIAMINGO, in *Biography*, a Flemish musician, by whom the Italians have been generally understood to mean Claude Goudimel, a native of Franche Compté, and a Hugonot, who was one of the first composers of music to the French translation of the psalms by Clement Marot and Theodore Beza; and who was murdered at Lyons in 1572, on the fatal day of the massacre of Paris.

There are certain difficulties in this account, of which we shall speak further elsewhere. See PALESTRINA.

MEL, in *Geography*, a town of Italy, in the Trevisan; 12 miles N.W. of Ceneda.—Also, a small island in the Atlantic, near the coast of Africa. N. lat. 13° 15′.

MEL. See HONEY.

MEL *Cedrinum*, in the *Materia Medica of the Ancients*, a term used to express a sort of liquid manna, used rather as a pleasant sweet in foods than as a medicine, and which seems to have been the same with the *mel roscidum* of Galen, and with the liquid manna of mount Sinai; that mountain having been the place where it was annually collected in large quantities even in Galen's time; and the account Bellonius gives of the manner of collecting it in his time, agreeing very well with what Galen has left about it. It is, however, an error in Bellonius, to suppose this to be the *terenjabin* of the Arabians, that being evidently a solid, not a liquid substance, and being from all accounts the same with what is now called *manna Persicum*, or Persian manna.

The mel cedrinum is a term used only by Hippocrates for this substance, and seems so odd, that many are apt to believe there is an error of the text, and that the author never meant any such thing. Foesius is of opinion, that these ought to be read as two distinct names, with a comma between them, and that the author only meant by them two substances very well known in his time, which were common honey, and the liquid substance called *cedrinum*, or *cedria*.

MEL *Roscidum*, a name given to a kind of liquid manna collected in their time, as it is at present, in considerable quantities, on mount Sinai. The monks who collect it call it *terenjabin*, after the name of a kind of manna, common among the Arabians. But this is an error, the terenjabin of those authors not being a liquid manna, but the small round kind, collected from the *alhagi maurorum*, and now called *manna Persicum*. It does not appear that the *mel roscidum*, or any other species of manna, was used in medicine by the ancients; this was esteemed a curiosity, rather than a thing of any use, by Galen; and other authors say, it was sweeter than honey itself, with no farther account; whence it seems rather to have been used as a delicacy than as a medicine. See TERENJABIN, and MANNA *Persicum*.

MELA, POMPONIUS, in *Biography*, an ancient geographical writer, was a native of Spain, and flourished A.D. 45. His great work, entitled "De Situ Orbis," divided into three books, is written with elegance, great perspicuity, and brevity. The best editions are those of Gronovius 1722, and Reinhold in 1761. Vossius gave an edition of it with copious notes. In the last edition by Gronovius are added five books "De Geographia," written by some later writer.

MELA, in *Geography*, a department of Italy, deriving its name from a river which rises on the confines of the Trenton, and after crossing the Bressan, runs into the Oglio, near Ustiano. The department is composed of part of the Bressan, and has a population of about 190,689 inhabitants, who elect 15 deputies.

MELA. See MEELAH.

MELA, a river of the Morea, which runs into the sea; 8 miles S.W. of Patras.

MELA, a surgeon's instrument, called also speculum, and by the vulgar a probe.

Its use is to probe ulcers, or draw a stone out of the penis; its form is various, according to the use it is intended for.

MELADA, in *Geography*, a small island in the Adriatic, a little to the N. of Isola Grossa. N. lat. 44° 35′. E. long 15° 56′.

MELÆNA, in *Medicine*, μελαινα νοσος in the language of Hippocrates (see his book περι νουσων, sect. 5. book ii. edit. Foës.) a disease characterized by a discharge of black matter by stool.

This affection sometimes occurs together with *hæmatemesis*, or vomiting of blood, and sometimes without that symptom. The ancients considered that the black matter thrown off by by the bowels, was that modification of bilious matter which they denominated *black bile:* but recent observation has ascertained that it consists principally of blood, in a grumous or semi-coagulated state, which is poured out slowly from the vessels of the inner coat of the intestines. It is observed generally to be connected with obstruction or congestion of some of the abdominal viscera, as of the liver, spleen, or mesentery. Great debility, and frequent fainting accompany the disease; the pulse is often quickened, though but moderately; and other symptoms of fever are seldom urgent. There is commonly severe pain in the stomach and abdomen, with loss of appetite, nausea or vomiting, head-ache, and other signs of derangement of the digestive organs.

Gentle purgatives and clysters have been recommended for this complaint from the time of Hippocrates downwards: and they are as beneficial in this affection, as in the hæmatemesis, to which it bears much affinity. (See HÆMATEMESIS.) Dr. Home employed the diluted sulphuric acid, in addition to laxatives, and, as he believed, with considerable advantage. Emetics he justly deems useless, if not injurious, and shunned the use of opium, as tending to shut up the matter that nature was carrying off. Opiates, however, combined with gentle cathartics, tend rather to aid the operation of the latter, by removing the spasmodic constrictions which take place in the bowels, and thus also afford material relief to the pains. See Home, Clinical Experiments, sect. 7.—Also Hoffman, Med. Rat. Syst. tom. iv. part. ii. sect. 1. cap. 3. Morgagni de Sed. et Causis Morbor. epist. xxx. art. 17. Sauvages, class ix. gen. 11. Portal, Mem. sur plusieurs Maladies, tom. ii. p. 129.

MELAGGE, in *Geography*, a river which rises in Algiers, formed by the union of several streams; which, in its course, takes the name of "Sarratt," and runs into the Mejerda, on the borders of Tunis.

MELAIPOUR, a town of Hindoostan, in the circar of Schaurunpour; 20 miles E.N.E. of Schaurunpour.

MELALEUCA, in *Botany*, from μελας, *black*, and λευκος, *white*, a very fine exotic genus of trees and shrubs, so named by Linnæus, because the principal, and indeed original, species was called *Leucadendron*, and *Arbor alba;* words synonimous with its appellation in the Malay tongue, *Caju-puti*, or White Tree. We know not why the idea of black was associated with white in the above name. Linn. Mant. 14. Sm. Tr. of Linn. Soc. v. 3. 273. Schreb. 332, excluding the synonyms. Willd. Sp. Pl. v. 3. 1428. Mart. Mill. Dict. v. 3. Juss. 323. Lamarck Illustr. t. 641. Gærtn. t. 35.—Class and order, *Polyadelphia Icosandria.* Nat. Ord. *Hesperideæ*, Linn. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, turbinate, in five deep, roundish, often coloured, equal segments. *Cor.* Petals five, roundish, inserted into the rim of the calyx, between its segments. *Stam.* Filaments very numerous, in five sets, inserted into the calyx, either opposite to, or alternate with, the petals, various in length and structure; anthers roundish, incumbent. *Pist.* Germen inferior, nearly globular; style thread-shaped, declining, shorter than the stamens; stigma obtuse. *Peric.* Capsule globose, coated, of three cells and three valves, the partitions from the centre of each valve. *Seeds* numerous, minute, angular.

Eff. Ch. Calyx superior, in five deep segments. Petals five. Stamens numerous, very long, in five parcels. Style one. Capsule of three cells.

A fine genus of aromatic trees and shrubs, with lateral inflorescence, and simple entire leaves, all, except the first species, the produce of New Holland. This genus was confounded by the younger Linnæus, the two Forsters, Schreber, and many other botanists, whom Jussieu seemed disposed to follow, with three other genera; see FABRICIA, LEPTOSPERMUM, and METROSIDEROS. From the two first it is clearly distinguished, as their characters will shew; from the last it differs merely in having the stamens assembled in five sets, not simply icosandrous; the habits of these two genera, and every part of their fructification, except the stamens, being alike. How very different the form of the filaments is in different species of *Melaleuca*, will appear by their descriptions; some being united to a great extent, others but slightly; some in a pinnate, others in a palmate manner; all which being considered, their union at all seems to afford but an artificial character. This however is a sufficiently clear, and, both genera being numerous, a very commodious distinction.

Eleven species of *Melaleuca* are described, by the writer of this article, in the third volume of the Linnæan Society's Transactions, and one in the sixth. These are all adopted by Willdenow. We shall here make some addition to the number, and Mr. Brown, in the second volume of his Prodromus, will probably increase it much more. The whole are distributed into two sections.

* *Leaves alternate.*

1. M. *Leucadendron.* Greater Cajeput Tree. Linn. Mant. 105. Suppl. 342, α. Sm. Tr. of Linn. Soc. v. 3. 274. (Myrtus Leucadendra; Linn. Sp. Pl. 676. Arbor alba; Rumph. Amboin. v. 2. 72. t. 16.)—Leaves alternate, lanceolate, pointed, obliquely falcate, five-ribbed. Footstalks, young branches, and germen, smooth.—Native of some parts of the East Indies, especially the Molucca islands, Ceram and Amboyna, growing in hilly places, flowering from January to March, and ripening fruit from August to November; but according to Rumphius, it is rarely propagated by seed. This is described by that accurate writer, as a large *tree*, as thick as a man's body, or much thicker, with many irregular widely spreading *branches*, but not of a lofty growth. *Leaves* scattered, on short smooth *footstalks*, lanceolate, entire, smooth, tapering at each end, but most at the extremity, curved laterally into a sickle shape, from five to eight inches long, scarcely an inch broad in the widest part, furnished with five principal ribs, connected by intermediate interbranching veins. *Stipulas* none. *Flowers* white, in long, loose, somewhat whorled spikes, whose smooth common stalk terminates in a leaf-bud, and becomes a branch. The bundles of *stamens* are $\frac{3}{4}$ths of an inch long, and each divided nearly to the base. *Germen* scarcely so large as a hemp-seed, globose, smooth, quite sessile, the *capsules* remaining long firmly fixed to the branch, surmounted by leaves, after the seeds have fallen out, as is common to the whole genus. Rumphius speaks much of the resinous and aromatic properties of this tree, its whitish or grey aspect, and its agreeable shade. The wood is hard and heavy, but easily splits and soon decays, being neither beautiful nor useful. The outer bark is of a spongy nature, and much used for caulking vessels, as it swells in the water; but is nevertheless liable to shrink again, and give way. It is called *baru*, a name given to all substances used for that purpose. An oil is obtained by firing the tree, which soon becomes thick and is used for candles. Rumphius says nothing of any fine essential oil being procured by distillation from this tree; see the next species.

2. M. *minor.* Lesser Cajeput Tree. Arbor alba minor; Rumph.

Rumph. Amboin. v. 2. 76. t. 17.)—Leaves ſcattered, elliptic-lanceolate, bluntiſh, ſtraight, five-ribbed. Young branches and germens downy.—Native of Amboyna, but leſs frequent than the foregoing, with which it has been confounded by every body but Rumphius. We now venture, for the firſt time, to diſtinguiſh them. This is ſmaller in all its parts, and rather a ſhrub than a tree. The young *leaves* are extremely ſilky; adult ones nearly ſmooth, about two (ſcarcely three) inches long, and one broad, exactly elliptical, and not oblique or falcated. *Footſtalks* broad and very ſhort, ſomewhat hairy. Young *branches*, where the *flowers* are ſeated, denſely clothed with white ſilky prominent down, as is likewiſe the *germen*. The *calyx* is but ſlightly downy. *Fruit* ſmooth, depreſſed and truncated.

The late Mr. Chriſtopher Smith, from whom we have received ſpecimens of both theſe plants, aſſured us of this being what yields the oil of Cajeput, and Rumphius gives the ſame account. (See CAJEPUT.) The bark is woody and brittle throughout, not externally corky like the former. The ſtructure of their parts of fructification is the ſame in both, eſpecially the form of the *ſtamens*. Rumphius's plates are by no means calculated to give a juſt idea of the foliage of either, eſpecially of the preſent, but his deſcriptions are excellent.

3. M. *viridiflora*. Green-flowered ribbed Melaleuca. Gærtn. v. 1. 173. t. 35. Sm. Tr. of L. Soc. v. 3. 275. (M. Leucadendron; Forſt. Prod. 38. Linn. Suppl. 342, β. Metroſideros quinquenervia; Cav. Ic. v. 4. 19. t. 333.)—Leaves alternate, elliptic-lanceolate, ſtraight, bluntiſh, coriaceous, five-ribbed. Footſtalks and young branches downy. Germen nearly ſmooth.—Native of New Caledonia and New South Wales. The younger Linnæus confounded it with both the preceding. From the firſt it is abundantly diſtinct. With the ſecond it more agrees in the ſhape of its *leaves*, but differs in their thick rigid texture, and much longer more downy *footſtalks* The *flowers* are twice as large, green, not white, with a ſmooth or very ſlightly hairy *germen*. The form of the *ſtamens* is the ſame. The young *leaves* of the preſent ſpecies are finely downy, but ſcarcely ſilky.

4. M. *ſuaveolens*. Sweet-ſcented Melaleuca. Gærtn. v. 1. 173. t. 35.—Leaves alternate, elliptical, ſingle-ribbed. Flower-ſtalks axillary, forked, downy, twice as long as the footſtalks. Filaments ſhorter than the petals, ſomewhat pinnate. Native of the warmer part of New Holland, near Endeavour river. A plate of this, communicated by ſir Joſeph Banks to Linnæus, is in our poſſeſſion. It appears to be a handſome *tree*, with elliptical ſmooth entire *leaves*, tapering at each end, ſingle-ribbed, five or ſix inches long and two broad. *Footſtalks* an inch long. *Flower-ſtalks* nearly twice that length, downy, axillary, ſometimes in pairs, forked, each bearing ſeven handſome white *flowers*, whoſe *ſtamens* are much ſhorter than the *petals*, and pinnated in their lower part. The *germen* and *calyx* are downy.

5. M. *laurina*. Laurel-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 275.—Leaves alternate, obovato-lanceolate, ſingle-ribbed. Flower-ſtalks axillary, forked, downy, about as long as the footſtalks. Filaments rather ſhorter than the petals, ſomewhat pinnate.—Native of New South Wales; communicated by ſir Joſeph Banks. It is very nearly related to the laſt, but not at all aromatic, which that ſhould ſeem by its name to be, and the *leaves* of the preſent are broadeſt towards the top, very narrow and taper at their baſe. The *footſtalks* are bordered, and ſo connected with the leaf, it is hard to fix the limits of each. *Flower-ſtalks* axillary, not an inch long, forked, ſilky, bearing five or ſeven *flowers*, half the ſize of the *ſuaveolens*. *Stamens* hairy, rather ſhorter than the *petals*. *Germen* and *calyx* downy.

6. M. *ſtypheloides*. Sharp Twiſted-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 275.—Leaves alternate, ovate, twiſted, many-ribbed, with a ſpinous point. Calyx-teeth ſharp-pointed, ribbed.—Native of Port Jackſon, New South Wales. This has the habit of a *Styphelia*, and is ſcarcely at all aromatic. The numerous *leaves* are ſeſſile, ſcattered, not an inch long, ovate, twiſted, rigid, pungent, entire, ſmooth, rather glaucous, ſtriated with innumerable nerves. Young *branches* very hairy, bearing in their lower part ſhort crowded circles of ſeſſile white *flowers*. *Germen* and *calyx* downy; the teeth of the latter erect, rigid, ſpinous, ribbed. *Stamens* palmate, much longer than the *petals*. M. Ventenat ſays, there were many fine plants of this ſpecies, in his time, at Malmaiſon, but none had then bloſſomed.

7. M. *ſquarroſa*. Various-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 6. 300. Donn. Cant. ed. 4. 186. (M. myrtifolia; Vent. Malmaiſ. t. 47.)—Leaves ſcattered or oppoſite, ovate, pointleſs, five or ſeven-ribbed. Calyx-teeth pointleſs, ſmooth.—Native of the eaſt and weſt coaſts of New Holland. We firſt ſaw it in the Cambridge garden in 1799. The *leaves* ſpread in three or four rows, according as they are ſcattered or oppoſite, they have about ſeven remote ribs, and are blunt without any ſpine. *Flowers* white, encircling the hairy branches in long denſe maſſes. *Germen* and *calyx* ſmooth, the latter blunt, without thorns or ribs. *Stamens* much longer than the *petals*, collected into five bundles, but not completely, many of the filaments being diſtinct, as in the genus *Citrus*; ſo that the limits between *Melaleuca* and *Metroſideros* here become almoſt evaneſcent. The *ſtigma* too in this ſpecies is quite ſimple, not ſo tumid or capitate as in moſt other *Melaleucæ*.—Perhaps *M. decuſſata* of Mr. Donn's *Hort. Cant.* ed. 5. 186, is but a variety of this.

8. M. *dioſmifolia*. Green-flowered Reflexed Melaleuca. Andr. Repoſ. t. 476.—Leaves ſcattered, reflexed, elliptic-oblong, obtuſe, ſingle-ribbed. Calyx-teeth rounded, ſmooth.—Native of King George's Sound, on the weſt coaſt of New Holland, where it was found by Mr. Menzies. We gathered it in flower, in June 1807, in the conſervatory of Claude Scott, eſq. at Sundridge park, Kent. A tall ſhrub, with many ſpreading *branches*, clothed with numerous, ſcattered, crowded, ſtalked, reflexed *leaves*, about half an inch long, nearly elliptical, dark green; ſmooth and even above; dotted and ſingle-ribbed beneath. The *flowers* are green in every part, rather large, thickly crowded for an inch or two along the middle part of each branch, their long *ſtamens*, which are united by their baſe into five bundles, projecting horizontally all round. The *anthers*, or at leaſt their *pollen*, is yellow. *Stigma* obtuſe. *Capſules* large, thickly coated, crowded into irregularly angular figures.

9. M. *microphylla*. Small-leaved Melaleuca.—Leaves ſcattered, imbricated, cylindrical, obtuſe, ſomewhat ſpreading. Flowers crowded at the upper part of the branches. This hitherto nondeſcript ſpecies was gathered near King George's Sound, on the weſt coaſt of New Holland, by Mr. A. Menzies, who favoured us with a ſpecimen. The *ſtem* is ſhrubby, much branched in a determinate manner; the *branches* ſmooth, whitiſh, leafy throughout. *Leaves* very numerous, crowded, a little ſpreading, about a quarter of an inch long, cylindrical or obſcurely quadrangular, very blunt,

blunt, unarmed, ſmooth, pale green, with a ſtrong aromatic reſinous flavour; each ſupported by a ſhort, ſlender, ſmooth *footſtalk*, jointed at its baſe. *Flowers* white, crowded into an oval ſpike at the ſummits of a few of the branches, which are not extended beyond them, but ſtill the infloreſcence is lateral. *Stamens* in five ſets, thoſe of each ſet united, a good way up, into a flat linear baſe or common filament, which reaches beyond the *petals*. *Germen* and *calyx* ſmooth. *Capſule* turbinate. This is moſt akin to the next.

10. M. *ericifolia*. Heath-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 276. Exot. Bot. v. 1. 65. t. 34.—Leaves ſcattered or oppoſite, linear, acute, nerveleſs, pointleſs, a little recurved. Flowers crowded at the upper part of the branches.—Native of Port Jackſon, New South Wales. This and the laſt are the ſmalleſt we have ſeen of the genus. Both have the habit of *Ericæ*. The preſent is very ſmooth in all its parts, and has the taſte and ſmell of Coriander ſeeds. The *branches* are prettily ſtriped with green and white. *Leaves* from half an inch to an inch in length, flattiſh, linear, very narrow, acute, but without any ſpinous point, deſtitute of rib or veins, a little convex beneath. *Flowers* yellowiſh-white, crowded into oval or oblong ſpikes at the top of almoſt every branch, which is commonly a little prolonged, and leafy, above them. *Germen* and *calyx* ſmooth. *Stamens* ſtrongly united in five ſets, but their common claws do not extend beyond the petals. The *flower-buds* are reddiſh.

11. M. *nodoſa*. Needle-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 276. Exot. Bot. v. 1. 67. t. 35. Vent. Malmaiſ. t. 112? Metroſideros nodoſa; Gærtn. v. 1. 172. t. 34. Cavan. Ic. v. 4. 19. t. 334.)—Leaves ſcattered, linear, ſtraight, tipped with ſpinous points. Flowers crowded near the tops of the little ſide branches. Filaments palmate.—From the ſame country as the laſt. It has long been known in the gardens. The ſtouter taller habit; ſtraight pungent *leaves* above an inch long; and the much ſhorter, almoſt globular, maſſes of yellow *flowers*, each of which is borne on a ſhort lateral branch, diſtinguiſh this ſpecies from the laſt. The flowering branches have leafy terminations. The bundles of *ſtamens* are palmate, their united part ſhorter than the petals.

12. M. *armillaris*. Slender-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 277. (M. ericæfolia; Andr. Repoſ. t. 175. Vent. Malmaiſ. t. 76. Metroſideros armillaris; Gærtn. v. 1. 171. t. 34.)—Leaves ſcattered, linear, ſomewhat recurved. Flowers crowded at the lower part of the branches. Filaments very long, linear; many-cleft and radiating at the ſummit.—Native of New South Wales. It has long been in the gardens. We have ſeen it trained againſt a wall to the height of ſeveral feet, in the open air, covered with flowers in May, and requiring only the ſhelter of a mat or glaſs frame in winter. It differs from *M. nodoſa* in its leſs rigid, and ſomewhat recurved, *leaves*, ſcarcely ſpinous at the tip; much longer ſeries of *flowers*, which are white; and particularly in the long linear baſe of each cluſter of *ſtamens*, which is extended to twice the length of the petals, and then branches off at once into numerous radiating filaments of no conſiderable length. We have always found the *flowers* ſituated about the lower part of each branch; Ventenat repreſents them near the end. So, on the contrary, his plate of *M. nodoſa* has the flowers on the lower parts of very long leafy branches, very different from what we have obſerved. It ſeems therefore that the relative ſituations of the fructification vary in theſe plants, though the comparative number of flowers in each is conſtant.

13. M. *geniſtifolia*. Broom-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 277. Exot. Bot. v. 1. 107. t. 55.—Leaves ſcattered, lanceolate, ſharp-pointed, three-ribbed, cloſely dotted. Flowers looſely ſcattered. Filaments pinnate in their upper part. Style hairy.—Native of New South Wales, where the firſt ſettlers called it the White Tea-tree. It is ſaid to grow "in a good ſoil, moſtly near the water-ſide," being covered with white bloſſoms in November. We have met with it in no garden. In its native ſoil the *ſtem* attains the height of twenty or twenty-five feet. The *branches* and *leaves* are ſmooth; the latter lanceolate, ſcarcely three quarters of an inch long, acute, flat, marked with three ribs, and numerous reſinous dots at the back. Their flavour is pleaſantly aromatic, not ſtrong. *Flowers* ſcattered, in alternate pairs, towards the tops of the ſmall terminal branches, which are ſlightly downy in that part. The claws of the united *ſtamens* are about as long as the petals before they divide; they then become pinnate, and towards the top are more cloſely branched. *Germen* and *calyx* ſmooth. *Style* hairy.

** *Leaves oppoſite.*

14. M. *linarifolia*. Toad-flax-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 278. Exot. Bot. v. 1. 109. t. 56. (Metroſideros hyſſopifolia; Cavan. Ic. v. 4. 20. t. 336. f. 1.)—Leaves oppoſite, linear-lanceolate, three-ribbed, cloſely dotted beneath. Flowers looſely ſcattered. Filaments pinnate all the way up. Style ſmooth.—Native of the country about Port Jackſon, New South Wales. We have ſeen it flowering at Mr. Scott's of Sundridge park. In its native ſoil this ſpecies forms a large *tree*, whoſe outer bark is eaſily ſtripped off, in large light thick ſpongy flaky portions, which ſerve the rude natives as a warm wrapper for their new-born infants. The European ſettlers found it anſwer the purpoſe of tinder. The *branches* are ſmooth. *Leaves* oppoſite, nearly ſeſſile, an inch and a half, or two inches long, narrow, linear-lanceolate, acute but not pungent, marked with three ſlight ribs above, much dotted on both ſides; the mid-rib keeled beneath. *Flowers* numerous, looſely diſpoſed, cream-coloured, with a tinge of red in the *petals*. *Stamens* very long, each bundle regularly pinnate, almoſt from the very baſe to the end. *Style* ſhort, ſmooth, as well as the *germen* and *calyx*. Every part is highly aromatic, with a flavour reſembling pepper-mint.

15. M. *abietina*. Fir-leaved Melaleuca.—Leaves oppoſite, elliptic-oblong, concave, blunt, ribleſs. Flowers few, at the ends of the branches. Filaments long, linear, many-cleft at the ſummit. Communicated by Mr. Menzies, who gathered it at King George's Sound, on the weſt coaſt of New Holland. This ſeems to be a ſtout *ſhrub*, or *tree*, with numerous, ſtrong, leafy, ſmooth *branches*. *Leaves* about half an inch long, crowded, oppoſite, in pairs croſſing each other, on ſhort broad *footſtalks*; they are concave above, with a very blunt point; convex beneath, deſtitute of ribs, veins, or dots. *Flowers* reddiſh, few together, in ſhort, ovate, apparently terminal ſpikes, beſet with many imbricated, reddiſh, ribbed and keeled *bracteas*. It ſeems doubtful whether the branches be ever continued, in a leafy form, beyond the inſertion of the flowers, which if they be not, would overſet a character in the habit of this genus on which we have always depended. Our ſpecimen however is inſufficient to decide this queſtion. The bundles of *filaments* are linear and ſimple to a conſiderable extent (but not to the extremities of the *petals*, which are longer than uſual); then they ſuddenly branch off into numerous diviſions, each bearing its *anther*, as in the other ſpecies. *Style* ſmooth, longer than in the laſt, but much ſhorter than the ſtamens. *Germen* and *calyx* ſmooth.

16. M.

16. M. *thymifolia.* Thyme-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 278. Exot. Bot. v. 1. 69. t. 36. (M. coronata; Andr. Repof. t. 278. M. gnidiæfolia; Vent. Malmaif. t. 4. Metrofideros calycina; Cavan. Ic. v. 4. 20. t. 336. f. 2.)—Leaves oppofite, elliptic-lanceolate, acute, riblefs. Flowers few together, on fhort lateral branches. Filaments oppofite to the petals, branched more than half way down.—Native of New South Wales. It was firft raifed in England, if we miftake not, by Mr. Fairbairn at Chelfea garden, and is not very uncommon in green-houfes. This fpecies is a little, flender, fmooth, bufhy *fhrub,* about two feet high, with numerous fmall, fmooth, oppofite thyme-like *leaves,* full of refinous dots beneath, and highly aromatic. *Flowers* rofe-coloured, abundant, though but few together, on fhort lateral *branches,* not always furmounted by leaves. The *germen* and *calyx* are fmooth. *Filaments* oppofite to the petals, which is remarkable, and as far as we can examine our dried fpecimens of others, peculiar to this and the next fpecies. They are twice the length of the petals, and confift of one broad flat compound filament, fending off from its margin and inner furface abundance of fimple filaments with *anthers,* almoft to its very bafe. *Style* fmooth, rather fhorter than the ftamens.

17. M. *hypericifolia.* St. John's-wort-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 279. Vent. Jard. de Cels, 10. t. 10. Andr. Repof. t. 200.—Leaves oppofite, fpreading, elliptic-oblong, fingle-ribbed. Flowers numerous, on fhort lateral branches. Filaments oppofite to the petals, very long, linear, radiating at the fummit.—Found in fwamps at New South Wales. This is now not unfrequent in the green-houfes and confervatories of England, where it makes an elegant appearance, being, in our opinion, the moft beautiful of the genus. The *ftem* is fhrubby, fix feet high, with lax fpreading branches. *Leaves* numerous, horizontal, oppofite, croffing each other in pairs, elliptical, fmooth, about an inch long, with much of the habit of an *Hypericum. Flowers* on fhort, lateral, fcattered branches, many together, in denfe cylindrical maffes. *Calyx* and *germen* fmooth, green, very glandular and refinous. *Petals* green or reddifh, with refinous dots at the back. *Filaments* oppofite to them, the common bafe of each clufter three or four times the length of the petal, and of the fame colour, linear and narrow, terminating in a very large radiating tuft of long, capillary, crimfon, filk-like threads, each bearing a fmall red *anther,* with yellow pollen. Thefe crimfon threads, combining all round into a clofe mafs, almoft concealing the reft of the flower, conftitute the chief beauty of the whole. It was miftaken for a *Bankfia* by one of the firft convicts who went to New South Wales, and who fent a very characteriftic drawing to England of this plant, among fome of lefs accuracy.

18. M. *neriifolia.* Oleander-leaved Melaleuca. Sims in Curt. Mag. v. 26. t. 1058. (M. falicifolia; Andr. Repof. t. 485.)—Leaves oppofite, lanceolate, fingle-ribbed. Flower-ftalks axillary, forked, nearly fmooth. Stamens fhorter than the corolla, fcarcely cohering.—Native of New Holland, we know not precifely from what part of that extenfive country. It is faid to have been firft raifed from feed by Mr. Barr of Iflington. This is very different from all the reft of the prefent fection, having yellow *flowers,* on axillary forked ftalks, being next akin in habit to *M. fuaveolens* and *laurina* of the former divifion; but its *leaves* are oppofite. Their figure is lanceolate, about two inches long, and the under fide is pale. The *ftamens* are defcribed by Dr. Sims as collected into five bundles, fhorter than the petals, but hardly cohering; Mr. Andrews delineates thefe bundles as oppofite to the petals, with the filaments feparate almoft to the very bafe. Whether Mr. Brown, from whom in his Prodromus v. 2, and Ait. Hort. Kew, we may expect additions to this genus, has made any generic divifion of it, we are not informed; but Dr. Sims hints at the propriety of fuch a meafure.

Mention of more fpecies than we have defined will be found in Mr. Donn's Hort. Cant. but fome of thofe are certainly not different. His *neriifolia* and *falicifolia* are, we prefume, our laft fpecies, under the names of Sims and Andrews. His *coronata,* and probably *fimbriata,* are our *thymifolia,* which he has likewife. His *diofmæfolia* and *armillaris* we judge to be one and the fame, as perhaps is his *ericifolia.* This intelligent botanift and cultivator is neceffarily liable to be mifled, by the communications of his friends, who fend the fame thing under different names; nor are the plants always in a condition for determination till it is too late for his purpofe. S.

Melaleuca, in the *Materia Medica.* The *Melaleuca minor* is that fpecies, which yields the *Cajeput* oil, and not the *M. leucadendron,* as mentioned under that article. See the preceding article.

The Cajeput oil, called alfo "Oleum Wittnebianum," from Wittneben, who gave an account of the procefs for obtaining it, though unknown in Britain, is now admitted into the Materia Medica of all the principal foreign pharmacopeias. It is imported into Europe from the Eaft Indies, and is diftilled chiefly in the ifland of Banda. From its exorbitant price it is frequently adulterated; and is therefore feldom found perfectly pure in Europe. Cajeput oil appears to be a powerful medicine, and is much efteemed in Germany, as well as in India, as a general remedy in chronic and painful complaints. It is ufed for the fame purpofes for which we employ the officinal ethers, to which it feems to have a confiderable affinity; the Cajeput, however, is more potent and pungent; taken into the ftomach, in the dofe of five or fix drops, it heats and ftimulates the whole fyftem, proving at the fame time a very certain diaphoretic, by which, probably, the good effects it is faid to have in dropfies and intermittent fevers are to be explained. For its efficacy in various fpafmodic and convulfive affections, it is highly efteemed; and numerous inftances of its fuccefsful employment are publifhed by different authors, cited by Murray. It has been alfo ufed both internally and externally with much advantage in feveral other obftinate diforders, as palfy, hypochondriacal and hyfterical affections, deafnefs, defective vifion, tooth-ache, gout, rheumatifm, menftrual obftructions, herpetic eruptions, &c.; of which Thunberg gives a particular relation. The dofe is from two to fix and even twelve drops. Woodville Med. Bot. See Cajeput *oil.*

MELALIEH, in *Geography,* a town of Egypt; 10 miles N. of Abugirgé.

MELAMPODIUM, in *Botany,* is a Linnæan genus whofe derivation may eafily be traced from μελας, *black,* and πους, *a foot.* According to the defcription of it in his *Hortus Cliffortianus,* it fhould feem that Linnæus had in view the fimilitude of the feed of the female florets to the foot of a goat. —In the *Critica Botanica* however it is faid to be named in honour of the Greek phyfician Melampus.—Linn. Gen. 445. Schreb. 583. Willd. Sp. Pl. v. 3. 2338. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 269. Juff. 188. Lamarck Illuftr. t. 713. Gærtn. t. 169.—Clafs and order, *Syngenefia Polygamia Neceffaria.* Nat. Ord. *Compofitæ Oppofitifoliæ,* Linn. *Corymbiferæ,* Juff.

Gen. Ch. *Common calyx* flat, much fpreading, of five, oblong-ovate leaves, the length of the florets. *Cor.* compound, radiated; the apparently perfect florets conftituting the

M E L.

the disk; female ones about five, making the radius: that of the florets of the disk of one petal, funnel-shaped, five-toothed, erect; of the radius ligulate, ovate, entire or three-toothed. *Stam.* in the disk, Filaments five, very small; anthers cylindrical, tubular. *Pist* in the same florets, Germen very small, abortive; style bristle-shaped, the length of the corolla; stigma obsolete: in the female ones, Germen nearly ovate, compressed, rough at the sides, flat and membranous at the top; style very short. *Peric.* none, except the unchanged calyx. *Seeds* in the disk none; in the radius solitary to each floret, obovate, compressed, quadrangular, prickly at the sides, crowned with a heart-shaped, partial calyx, involute and converging at the margin. *Recept.* chaffy, conical; scales lanceolate, coloured, the length of the florets.

Eff. Ch. Receptacle chaffy, conical. Seed-down of one leaf, converging. Common calyx of five leaves.

1. M. *americanum*. Linn. Sp. Pl. 1303. (Caltha americana, &c., Banks. Reliq. Houst. 9. t. 21.)—Stem erect. Leaves linear-lanceolate, pinnatifid.—Found by Houston, near Vera Cruz, in a craggy, sandy soil, where it flowered and ripened fruit in March.—*Stems* herbaceous, numerous, round, villose, procumbent. *Leaves* opposite, an inch and half long, usually with two lateral segments, sometimes entire; hairy on both sides, but more particularly at the back. *Flowers* solitary, yellow, upon axillary stalks. *Seeds* forming a crown, and supplying the place of the florets of the radius.

The specific character of this plant given in the *Species Plantarum* of Linnæus differs so much from Houston's figure, as well as from the description in *Hortus Cliffortianus*, which seems made from the same specimen, that we have presumed to alter it.—Possibly when he wrote the second edition of the *Species Plantarum*, not having any specimen before him, he did not sufficiently attend to what he had previously recorded.

2. M. *humile*. Swartz. Prod. 114. Ait. Hort. Kew. ed. 1. v. 3. 269.—Stem erect. Leaves toothed, somewhat lyrate, sessile.—A native of Jamaica and St. Domingo, flowering from June to October.—Nothing is known of this species but from the authors above quoted, and not being able to refer either to a specimen or a figure of it, we must of course be content with copying their specific character.

3. M. *australe*. Linn. Sp. Pl. 1303. Willd. n. 3. (M. australe, feminibus quinque oblongis hispidis, calyce pentaphyllo, caule decumbente; Lœfl. It. 268.)—Stem decumbent. Leaves oval, serrated.—Found at Cumana in South America by Lœfling, who describes the *Root* as perennial. *Stems* a span long, somewhat downy, with opposite decumbent *branches* ascending towards their extremities. *Leaves* opposite, on footstalks, oval or obtusely ovate. *Flowers* terminal, yellow, on short footstalks. *Seeds* furrowed, and covered with hooked hairs.

These three species are all that are known of the genus *Melampodium*. Of the two last we are not acquainted with any figure. Professor Martyn observes, that they are all tender plants requiring much shade and warmth. The seeds should be sown in the spring in a hot-bed, and the plants removed in due time into pots filled with light sandy earth.

Melampodium, in the *Materia Medica*. See Hellebore and Helleborus.

MELAMPUS, in *Biography*, was enumerated among the early civilizers of Greece, who thought it necessary to travel into Egypt to qualify themselves for the high employments at which they aspired in their own country. Orpheus proceeded thence a legislator and philosopher; and Melampus, who had different views, commenced, at his return, physician and diviner, arts which in Egypt were professed together. Apollodorus says, that he was the first who cured diseases by medicinal potions. Physic had its miraculous powers during the infancy of the art, as well as music; and life and health being esteemed more precious and solid blessings than the transient pleasures of the ear, bore a much higher price: for though bards were often distinguished by royalty, and their talents recompensed by gifts and honours, yet we do not find in ancient records that any one of them ever experienced such munificence as Melampus. It is related by Pausanias, that having cured the daughters of Prætus, king of Argos, of an atrabilarious disorder, with hellebore, he was rewarded with one of his royal patients for wife, and a third part of her father's kingdom in dowry.

MELAMPYRUM, in *Botany*, is the Μελαμπυρον of Theophrastus, derived from μελας, *black*, and πυρος, *wheat*; its seeds greatly resembling the grain of wheat, but of a darker colour. In some however, indeed in all the Linnæan species, they are so like wheat in form, size and colour, as to be scarcely discernible from it.—Cow-wheat.—Linn. Gen. 305. Schreb. 401. Willd. Sp. Pl. v. 3. 197. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 651. Ait. Hort Kew. ed. 1. v. 2. 328. Tournef. t. 78. Juss. 101. Lamarck Dict. v. 4. 19. Illustr. t. 518. Gærtn. t. 53.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, permanent, cloven half way down into four, slender segments. *Cor.* of one petal, ringent; tube oblong, recurved; limb compressed: upper lip helmet-shaped, compressed, emarginate, the lateral little margins reflexed; lower lip flat, erect, the length of the upper, obtuse, cloven half way down into three, equal segments, marked with two prominences in the middle. *Stam.* Filaments four, awl-shaped, curved, concealed under the upper lip, two of them shorter; anthers oblong. *Pist.* Germen superior, acuminate; style simple, in place and length like the stamens; stigma obtuse. *Peric.* Capsule oblong, oblique, pointed, compressed, its upper margin convex, the lower straight, of two cells and two valves, opening at the upper suture; partition contrary. *Seeds* in pairs (solitary according to Gærtner), ovate, gibbous, enlarged at the base.

Eff. Ch. Calyx tubular, four-cleft. Upper lip of the corolla compressed, folded back at the margin. Capsule of two cells, oblique, bursting at one edge. Seeds two, gibbous.

1. M. *cristatum*. Crested Cow-wheat. Linn. Sp. Pl. 842. Engl. Bot. t. 41.—Spikes quadrangular. Bracteas heart-shaped, imbricated, compact, toothed.—An English plant, though by no means a common one. It has been found both in Cambridgeshire and in Norfolk, on the borders of woods, and in corn-fields, flowering in July. The specimen figured in English Botany was sent from Madingley wood, near Cambridge.—*Root* annual. *Stem* rough, much branched. *Leaves* opposite, linear, entire. *Spikes of flowers* terminal, imbricated, very ornamental, being of a yellow, purple and tawny colour.—Linnæus however observes that there is a variety which has white flowers.

2. M. *arvense*. Purple Cow-wheat. Linn. Sp. Pl. 842. Engl. Bot. t. 53.—Spikes conical, loose. Bracteas fringed with narrow taper teeth.—This like the last may be considered as a rare native plant, though occurring occasionally in various parts of England, in gravelly fields, and flowering in July and August.—*Root* annual. *Stem* about two feet high,

high, erect, much branched, rough. *Leaves* lanceolate, pointed, entire. *Spikes of flowers* terminal, of a yellow and purple colour, extremely ornamental, indeed so much so that Dr. Smith observes "we are scarcely worthy to possess it, for its charms, however striking, have never procured it admission into a flower-garden, though it may easily be raised from fresh seed on a dry gravelly soil."

3. M. *barbatum.* Bearded Cow-wheat. Willd. n. 3. Wadstein and Keitabel Pl. Rar. Hung.—Spikes conical, loose. Bracteas toothed and bristle-shaped, not coloured. Calyx-teeth bearded. Corolla gaping.—A native of fields in the south of Hungary.—This new species is adopted on the authority of Willdenow, who says that it is very closely allied to the last, but differs in the following particulars. *Bracteas* green, not coloured. *Calyx-teeth* furnished with long, transparent, membranous hairs at the margin. Upper lip of the corolla more hairy. *Flowers* by no means variegated, but altogether of a yellow colour.

4. M. *nemorosum.* Many-coloured Cow-wheat. Linn. Sp. Pl. 843. Fl. Suec. 214. Fl. Dan. t. 305.—Flowers leaning one way, lateral. Bracteas toothed, heart-shaped, lanceolate, the upper ones coloured, sterile. Calyx woolly.—A native of woods in the north of Europe, and especially of some provinces of Sweden. Dr. Smith also found it in Savoy.—It flowers in July and August.—*Root* annual, small. *Stem* somewhat more than a foot in height, upright, branched. *Leaves* entire, ovate, pointed, occasionally rather arrow-shaped, toothed at the base. *Bracteas* violet-coloured, laciniated at the base, those at the top barren. *Flowers* of a beautiful yellow and purple colour.—The splendour of this species has attracted the notice of various botanists. Linnæus mentions it in his *Flora Suecica* with great delight, which has drawn forth the following observation from Dr. Smith in his Tour on the Continent, ed. 2. v. 3. 149. Speaking of *M. nemorosum* he says, "The red and yellow flowers, amid sky-blue and purple bracteæ, form the richest combination possible, which, but in the hands of nature, would be tawdry. Well might Linnæus esteem this plant worthy to decorate the palace of Flora herself."

5. M. *pratense.* Common yellow Cow-wheat. Linn. Sp. Pl. 843. Engl. Bot. t. 113.—Flowers lateral, leaning one way. Leaves in distant pairs. Corolla closed.—Common in woods and thickets throughout England, flowering through the summer.—*Root* annual, branched, spreading, smooth. *Stem* slender, branched. *Leaves* lanceolate, smooth, occasionally toothed at the base. *Bracteas* pinnatifid, often purplish. *Flowers* solitary, all leaning one way, yellow, their upper lip fringed with dense hairs, the lower one straight; anthers cohering together at their tips.—We find the following observation in English Botany. "Linnæus says, the best and yellowest butter is made where this plant abounds. All authors have copied him, and we do not scruple to do the same, in hopes that somebody will in time be induced to make experiments on the subject in England, where this plant is far from uncommon, flowering all summer long."—This property of M. *pratense* is mentioned in the Lapland Tour of Linnæus v. 1. 110, as well as in the *Flora Lapponica* n. 240, where he confounds it with the following as one species.

6. M. *sylvaticum.* Wood Cow-wheat. Linn. Sp. Pl. 843. Engl. Bot. t. 804.—Flowers lateral, leaning one way. Leaves in distant pairs. Corolla open, with its lip bent downwards.—Found occasionally in mountainous woods or pine forests, flowering in July.—The habit of this species is extremely similar to that of the last, but it is upon the whole considerably smaller.—*Root* annual. *Stem* roughish. *Leaves* a little broader, less black from drying, all of them generally entire. *Flowers* twice as small, of a yellowish-orange colour, especially at the mouth. *Capsule* marked with a net-work of prominent veins.

7. M. *lineare.* Linear Cow-wheat. Willd. n 7. Lamarck Dict. v. 4. 23.—Leaves linear, entire. Flowers axillary. A native of Carolina, where it was discovered by Mr. Fraser.—All that we know of this is from the authors above quoted, who tell us that it is more diminutive than any other species of this genus, in habit greatly resembling *Euphrasia linifolia.*—*Root* annual. *Stem* about five inches high, round, erect, furnished with opposite, somewhat quadrangular, branches. *Leaves* opposite, sessile, an inch long, little more than a line broad, acute. *Flowers* in the bosoms of the upper leaves, about three lines in length. *Calyx* half the length of the *corolla,* which is gaping, with equal lips, the upper one obtuse, villose at the margin.

The several species of *Melampyrum,* though extremely elegant and ornamental when fresh, are at the same time remarkable for turning brown or black when dry, losing all traces of their living beauty, and making a shabby appearance in the Herbarium. "The seeds of this genus have a remarkable resemblance to grains of wheat; on which account (says Dr. Smith) we prefer the old English name to that of *Cow-grass,* given by Dr. Stokes."

MELAN PHARMACON, a word used by Hippocrates, and by some supposed to mean common writing ink. He orders this to be poured upon the cranium, in case of a fissure, in order to discover how far it has penetrated. Galen seems to refer to this, in some places, and mentions his having treated of it in his book of ulcers; but as no such medicine is found prescribed here, it is probably one of the lost compositions of the ancients. In the spurious edition of Hippocrates, his book treating on the diseases of women, there is a black medicine ordered to be made of the squamæ and flos æris.

MELANA, or MÆLENA, in *Ancient Geography,* a town of Arcadia, in the western part, on the river Alpheus, S.W. of Telphusia.

MELANAETOS, in *Ornithology.* See FALCO.

MELANAGOGUES, MELANAGOGA, from μελας, *black,* and αγω, *I draw,* such medicines as were believed to possess the particular power of evacuating *black bile,* one of the four humours of the ancient pathology.

MELANANTHERA, in *Botany,* was so called by Michaux, from μελας, *black,* and ανθηρα, *an anther,* because of the colour of the anthers, which is strongly contrasted with the white corolla. Michaux Boreali-Amer. v. 2. 106.—Class and order, *Syngenesia Polygamia-æqualis.* Nat. Ord. *Compositæ oppositifoliæ,* Linn. *Corymbiferæ,* Juss.

Gen. Ch. *Common calyx* imbricated, of several, not very numerous, oval, flattish, close-pressed, unarmed leaves, in two rows. *Cor.* compound, discoid; florets uniform, numerous, all perfect, though some of the central ones are usually abortive; all funnel-shaped, with a short tube, and a much longer and wider, tubular, five-cleft, regular limb, whose segments are lanceolate and cohering. *Stam.* Filaments five; anthers forming a cylinder, shorter than the corolla. *Pist.* Germen obovate, angular, abrupt; style thread-shaped, projecting a little beyond the anthers; stigmas two, oblong, revolute, slightly tapering. *Peric.* none, except the permanent calyx. *Seeds* turbinate, quadrangular, smooth, abrupt at the top, with a small annular border, and a crown of very few, (about five,) erect, rough, deciduous bristles. *Recep.* rather convex, with a firm, keeled, concave, ribbed scale to each floret, at length overtopping the seeds and much resembling the calyx-scales.

Eff. Ch. Receptacle convex, with obovate, keeled, rigid scales.

scales. Seeds square. Crown of a few rough bristles. Calyx of two rows of uniform, ovate, imbricated leaves.

Obs. This genus differs so much in habit from *Bidens*, with which Linnæus confounded it, that we cannot but think Michaux right in separating them. The ovate uniform calyx-leaves, and the scales of the receptacle, so closely resembling them, in the seeding state, that the whole head of seeds assumes one uniform scaly aspect, added to the number and nature of the bristles of the seed-crown, which are not in one or two pairs, but of an indeterminate number, all uniform, and rough with minute ascending points, not barbed with sharp reflexed spines; these characters are surely sufficient marks of distinction.

1. M. *hastata*. Michaux. v. 2. 107. (Bidens nivea β and γ; Linn. Sp. Pl. 1167. B. scabra, flore niveo, &c.; Dill. Elth. t. 46 and 47.)—Leaves three-lobed, somewhat hastate. Scales of the receptacle lanceolate, taper-pointed.—Native of Carolina. It was cultivated in the Eltham garden before the year 1732, and flowered late in autumn. The *root* is perennial. *Stems* herbaceous, two or three feet high, rough, somewhat branched, leafy. *Leaves* opposite, stalked, rough and harsh, serrated; sometimes slightly, sometimes very deeply, hastate. Dillenius figures both varieties. *Flowers* terminal, an inch broad, on long stalks. *Corollas* white. *Anthers* black. This probably is the *Bidens nivea* of Mr. Donn's Hort. Cant., which is there marked as a hardy perennial, flowering in June and July.

2. M. *deltoidea*. Michaux. v. 2. 107. (Bidens nivea α; Linn. Sp. Pl. 1167. Swartz. Obs. 296. Ait. Hort. Kew. ed. 1. v. 3. 154. Calea aspera; Jacq. Ic. Rar. t. 583.)—Leaves ovate or heart-shaped, all undivided. Scales of the receptacle bluntish.—Native of the West Indies. Swartz says it grows in grassy, cultivated, elevated situations, as well as near the sea, in the south part of Jamaica. The late Mr. Aiton gave us a specimen from Kew garden, in 1783, as a great rarity. This is, of course, more tender than the former, from which it differs in the ovate, somewhat deltoid or cordate, form of the *leaves*, one of which is exhibited by Dillenius in his t. 47. f. 3. The *flowers* too are rather smaller.

MELANCHOLY. See MENTAL *Derangement*.

MELANCRANIS, in *Botany*, from μελανα, *blackness*, and κρανον, *a head*, alluding to the dark purplish spots with which the scaly roundish head of the flowers is besprinkled, and which give it a black aspect. Vahl. Enum. v. 2. 239.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juss.

Gen. Ch. *Cal.* Scales of a *spike*, imbricated every way, ovate, pointed, each subtending an oblong, compressed, two-ranked, nearly seven-flowered *spikelet*, of the same length. Perianth inferior, of two valves, shorter and narrower than the corolla. *Cor.* of one lanceolate valve, closely dotted with purple. *Stam.* Filaments three, linear, the length of the scales, whitish dotted with purple; anthers linear. *Pist.* Germen oblong; style solitary, smooth, cloven; stigmas simple. *Seed* one, without any bristles at its base.

Eff. Ch. Scales chaffy, imbricated every way. Spikelets solitary at every scale, many-flowered, two-ranked. Calyx of two valves. Corolla of one valve. Style cloven.

1. M. *scariosa*. Vahl. n. 1. (Schoenus scariosus; Thunb. Prod. 16.)—Head oblong. Bracteas about three.—Native of the Cape of Good Hope. *Root* perennial. *Stems* in tufts, about a foot high, or rather less, thread-shaped, rigid, without joints, finely striated, angular at the top. *Leaves* shorter, bristle-shaped, channelled, dilated into a sheathing base. *Head of flowers* terminal, half an inch in length, oblong, composed of imbricated, ovate, broad, membranous, rather rigid, smooth, shining *scales*, each a little spreading at the point, and tapering into a sort of awn; the three lower ones barren, tipped with a bristle-like leaf or *bractea*, which in the lowermost is three inches long. *Spikelets* five-flowered.

2. M. *radiata*. Vahl n. 2.—Head nearly globose. Bracteas numerous.—From the same country. Perennial. Rather taller than the first. *Bracteas*, or barren scales, at the base of the head of flowers, from six to eight, one of them half an inch long, the rest gradually less, widely spreading, awl-shaped, rigid and somewhat pungent. *Head* the size of a cherry, composed of innumerable, ovate, crowded *spikelets*; their accompanying *scales* striated and dotted with purple.

MELANCTHON, PHILIP, in *Biography*, an illustrious reformer, and coadjutor of Luther, was born at Bretten, in the Palatinate upon the Rhine, on the 16th of February 1495. His family name, in the German language, literally meant "Black Earth," which was exchanged for Melancthon, a word in the Greek tongue having the same signification. He received the early part of his education at his native place, was afterwards placed under the care of a private tutor, and then proceeded to the college of Pfortsheim, where he obtained the friendship of the learned Reuchlin, from whom he received the Greek name already alluded to, by which he is generally known. In 1509 he removed to Heidelberg, where he made so rapid a progress in the classics and other branches of literature, that before he had completed his fourteenth year he was entrusted with the tuition of the sons of count Leonstein. He is accordingly celebrated by Baillet, in his "Historical Treatise of young Men who became famous by their Study or Writings." At the age of thirteen he wrote a comedy, which he dedicated to his friend and patron Reuchlin; and at that period he was employed to make the greatest part of the harangues and orations which were delivered in public, in the university of Heidelberg. In 1511 he was admitted to the degree of B.A.; but being refused his superior degree in the arts in the following year, he left the college, and entered himself at Tubingen. Here he pursued his studies with great diligence and success, and became himself a lecturer on the Latin classics. In 1513, before he had attained the age of seventeen, Melancthon was created doctor of philosophy. It was about this period that Erasmus paid him the following high compliment: "What hopes may we not entertain of Philip Melancthon, who, though as yet very young, and almost a boy, is equally to be admired for his knowledge in both languages? What quickness of invention!—what purity of diction!—what powers of memory!—what variety of reading!—what modesty and gracefulness of behaviour!" While at Tubingen, Melancthon diligently studied the sacred Scriptures, and always carried about with him a bible, which he had received as a present from Reuchlin. This treasure, it may be said, he bound to his heart: he was hardly ever seen without it; and, during divine service, he frequently referred to its contents: and on this account, those who were jealous of his rising fame endeavoured to excite prejudices against him, by insinuating that he spent his time at church in reading what did not belong to the solemnities of the service. In 1518 he was appointed by the elector of Saxony professor of the Greek language in the university of Wittemberg, and by his inaugural speech excited the highest applause and admiration. He now began to read lectures upon Homer, and the Greek text of the Epistle of St. Paul to Titus, which attracted vast crowds of auditors, and which contributed, in no small degree, to

 promote

promote the ſtudy of Greek literature. In the year 1519 he publiſhed his "Rhetoric;" and in the following year, a treatiſe on "Logic;" and four years after this, his work on "Grammar." From the time of his ſettling at Wittemberg, Melancthon contracted a cloſe intimacy with Luther; and in the year 1519 he accompanied him to Leipſic, to be a witneſs of his eccleſiaſtical combat with Eckius. He ſeems not to have been contented to be a mere bye-ſtander, but joined ſo much in the debate as to provoke the rage and bitterneſs of Eckius, who found himſelf completely overwhelmed with the arguments brought againſt the cauſe, which he undertook to juſtify and defend. Melancthon, from this moment, became an advocate in the cauſe of reform, and, by the ſervices which he afterwards rendered it, made his name immortal. In the year 1520 he delivered a courſe of lectures at Wittemberg on the Epiſtle to the Romans, with which Luther was ſo highly pleaſed, that he cauſed it to be printed, and prefixed a preface of his own, recommending it to the uſe of the churches. In the following year he undertook a defence of the doctrines of Luther, in oppoſition to the univerſity of Paris, which had paſſed a ſentence of condemnation upon them. The next buſineſs of importance in which he was engaged, was to draw up, conjointly with Luther, a ſyſtem of laws relating to church government, public worſhip, the ranks, offices, and revenues of the prieſthood, and other matters of a ſimilar nature, which John, elector of Saxony, promulgated in his dominions, and which was adopted by the other princes of the empire, who had renounced the papal ſupremacy and juriſdiction. After this, Melancthon was commiſſioned, with others, to viſit all the churches in the electoral dominions, for the purpoſe of ſeeing theſe laws carried into execution.

In the year 1529, Melancthon accompanied the elector John to the diet at Spire, in which the princes and members of the reformed communion acquired the denomination of Proteſtants, in conſequence of their proteſting againſt a decree, which declared unlawful every change that ſhould be introduced into the eſtabliſhed religion, before the determination of a general council was known. In the year 1530 a diet of the empire was appointed to be held at Augſburg, with a view to put an end to the diſſentions occaſioned by religious diſputes, under the eye of the emperor, in order that he might be able to form a clear idea of the real opinions of the reformers, and of the true cauſes of their oppoſition to the Roman pontiff. The Proteſtant princes employed Melancthon to compoſe a creed, which was preſented to the emperor, and which reflects honour on the addreſs, moderation, and eloquence of Melancthon. This creed, commonly known by the name of the "Confeſſion of Augſburg," was ſeverely animadverted upon by his opponents, which led him to draw up an able reply, notwithſtanding the imperial prohibition, under the title of "A Defence of the Confeſſion of Augſburg." Recourſe was now had to conferences, in which our reformer mightily diſtinguiſhed himſelf. It was in theſe that the ſpirit and character of Melancthon appeared in their true colours; and it was here that the votaries of Rome exhauſted their efforts to gain over to their party this pillar of the reformation, whoſe abilities and virtues added a luſtre to the cauſe in which he had embarked. His gentle ſpirit was apt to ſink into a kind of yielding ſoftneſs, under the influence of mild and generous treatment. Accordingly, while his adverſaries ſoothed him with fair words and flattering promiſes, he ſeemed ready to comply with their wiſhes; but when they ſo far forgot themſelves as to make uſe of threats, then Melancthon appeared in a very different point of light: then a ſpirit of intrepidity, ardour, and independence animated all his words and actions, and he looked down with contempt on the threats of power, the frowns of fortune, and the fear of death.

As every attempt at reconciliation had proved in vain, a ſevere decree was iſſued by order of the emperor, enjoining the princes, ſtates, and cities, that had thrown off the papal yoke, to return to their duty, and their allegiance to Rome, on pain of incurring the indignation of the emperor, the patron and protector of the church. This at firſt oppreſſed the gentle ſpirit of Melancthon, till he was encouraged and animated by the exhortations of Luther; and he ſoon had the ſatisfaction to ſee the Proteſtant intereſt ſtrengthened and extended, owing to the treaty concluded at Nuremberg, of the expediency of which the emperor was made fully ſenſible, by the league of Smalkalde, and other circumſtances. Melancthon's fame was now ſpread far and wide, and he was invited by Henry VIII. to ſettle in England, and, about the ſame time, by Francis I. to take up his abode in France, with the view of employing him to pacify, or at leaſt to moderate the diſputes which had ariſen there concerning religion, and to adviſe with the French divines about reſtoring the ancient diſcipline of the church. Melancthon felt inclined to accept the latter invitation; but the elector of Saxony would not by any means give his conſent, knowing that by ſuch a ſtep he would expoſe himſelf to the reſentment of the emperor, between whom and Francis affairs began to wear a hoſtile aſpect. In 1541 Melancthon was at the famous conferences at Ratiſbon; and in 1543 he went to Cologne, to aſſiſt the elector in introducing the reformed religion into his dioceſe; but the main deſign of his journey was fruſtrated, through the oppoſition of the canons and other divines of the ſee: neverthele ſs the elector of Cologne and the elector palatine embraced the Proteſtant faith. In 1548 he aſſiſted at ſeven conferences on the ſubject of the interim of Charles V., and publiſhed a cenſure on that interim, and all the writings preſented at theſe conferences. In 1551, pope Julius III. having conſented to the aſſembling a council at Trent, the Saxon Proteſtants employed the pen of Melancthon, and the people of Wittemberg that of Bredlius, to draw up confeſſions of their faith, to be laid before the council. Soon after, the Saxon divines, with our reformer at their head, received directions from Maurice, now elector of Saxony, to ſet out towards Trent, but were ſecretly inſtructed to ſtop at Nuremberg, as Maurice had no intention to ſubmit to the emperor's views, and the ſchemes which he had been long preparing, with the deepeſt policy, for maintaining the rights and liberties of the German empire, and the ſecurity of the Proteſtant faith, and which were on the eve of being carried into execution. While he was at Nuremberg, in 1552, Melancthon received intelligence of the complete ſucceſs which had crowned Maurice's well-projected undertaking, and compelled the emperor to conclude the famous pacification at Paſſau, commonly called "The Peace of Religion."

Upon this event he intended to have returned to Wittemberg, but as that city was then infected with a plague, the univerſity had been removed for a time to Torgau, where Melancthon diſcharged the duties of his profeſſorſhip, till the infectious diſorder was completely baniſhed. To theſe duties he devoted the remainder of his life, as well as in the compoſition of various works, and the carrying on of controverſies with his Proteſtant and Catholic opponents. His laſt conference was with the doctors of the Romiſh communion at Worms. The firſt point diſcuſſed was concerning the rule of judgment in the church, which the Catholics maintained to be perpetual conſent or cuſtom;

2 but

but the Protestants, in conformity with their own principles, held it to be the prophetic and apostolical writings. In the next place the Catholics demanded a decree of condemnation against the followers of Zuingle, and others, when the deputies of Jena perceiving the disposition of the majority to agree to this demand, broke off the conference, by seceding from the meeting; and thus the object of the Papists to promote a division among the Protestants was effectually gained. From Worms, Melancthon went to Heidelberg, at the request of Otho Henry, elector palatine, for the purpose of giving his advice in forming the constitutions of an academical institution established in that city. In 1559 he made an attempt to bring over the Greek churches to embrace the doctrine and discipline of the Lutheran church, and to live in religious communion with the Protestants; in which his laudable endeavours were ineffectual. He died in the following year at Wittemberg, in the sixty-fourth year of his age, and was interred near the remains of Luther. "Nature," says one of this great man's biographers, "had given Melancthon a peaceable temper, which was but ill suited to the time he lived in. His moderation served only to be his cross. He was like a lamb in the midst of wolves. Nobody liked his mildness: it looked as if he were lukewarm." He was a person of the middle stature, with lively eyes and well-proportioned limbs, but his constitution was delicate and his health weak, yet by the exercise of the most rigid temperance, he was enabled to pursue his studies with an intenseness of application that is almost incredible. The habits of such a man cannot fail of interesting those who reflect on what he did for the world: it was his practice to go to bed immediately after an early supper, and to rise at midnight to his labours. On retiring to rest he endeavoured to dismiss as much as possible from his mind every thing that could tend to disturb his repose, and for this purpose he always postponed reading such letters as were brought to him in the evening till next day. He was civil and obliging to all; entirely free from envy, detraction, jealousy, and dissimulation; and possessed an unrivalled degree of candour and frankness. His principal relaxation from severe studies was the conversation of his friends during his meals. He was humble and extremely disinterested, constantly refusing the valuable presents which were offered him by many great princes, and contenting himself with the small profits of his professorship; yet he managed his narrow income with such admirable economy, that he was able to indulge his benevolent and charitable disposition to an astonishing degree. According to the testimony of Mosheim, few worthies can be compared with him, if we consider the extent of his knowledge, the fertility and elegance of his studies, the facility and quickness of his comprehension, or the uninterrupted industry that attended his learned and theological labours. He rendered philosophy and the liberal arts the same eminent service that Luther had done to religion, by purging them from the dross with which they had been corrupted, and by recommending them in a powerful and persuasive manner to the study of the Germans. He had the rare talent of discerning truth in all its connections and combinations, of comprehending at once the most abstract notions, and expressing them with the utmost ease and perspicuity. His love of peace, which was partly owing to the sweetness of his natural temper, made him desire with ardour, that a reformation might be effected without producing a schism in the church. The spirit of charity led him sometimes to make concessions that were neither consistent with prudence, nor advantageous to the cause in which he was engaged. But when the hour of real danger approached, when things wore a formidable aspect, and the cause of religion was in imminent peril, then this mild and even timorous man, in an instant, as it were, was converted into a hero, looked danger in the face with unshaken constancy, and opposed his adversaries with invincible fortitude. Had his fortitude been more uniform and steady, his desire of reconciling all interests, and pleasing all parties less excessive, he must deservedly have been considered as one of the greatest among men.

In philosophy he followed chiefly the principles of Aristotle, and had frequently recourse to the doctrines of the Platonists and Stoics, but always in due subordination to revelation, and only so far as they were likely to answer some valuable purposes. "I would have no one," says he, "trifle in philosophising, lest he should lose sight of common sense; rather let him be careful, both in the study of physics and morals, to select the best things from the best sources. He may not, therefore, improperly be considered as an *eclectic*."

Melancthon was much assisted in the execution of his plans by the labours of many learned Protestant professors of the Germanic schools from Italy and Great Britain, who brought with them an attachment to the Peripatetic system, and wherever they were appointed public preceptors, made that system the basis of their philosophical instructions. From Wittemberg, Tubingen, and Leipsic, conducted after the plan which had been introduced by Melancthon, many learned men arose, who, becoming themselves preceptors, adopted the same plan of instruction, which, from Melancthon's Christian name, was denominated "The Philippic Method," and thus disseminated the Peripatetic doctrine, till at length it was almost every where taught in the German Protestant schools, under the sanction of civil and ecclesiastical authority. The number of the works which Melancthon published, considering how much he was engaged as a public man, is truly astonishing. The titles of a great many of them are given in the General Biography. They are theological, moral, and philosophical; some, however, relate to what is usually denominated the Belles Lettres, and others are illustrative of various classical authors. The most complete edition was published by the author's son-in-law, Jasper Peucer, in the year 1601, in 4 vols. fol.

This celebrated and mild reformer, the friend of Martin Luther, and author of the confession of Augsburg, &c. wrote upon music. He composed his own epitaph, and died in 1560.

"Iste brevis tumulus miseri tenit ossa Philippi,
Quis, qualis fuerit nescio, talis erat."

MELANES, or MELAS, in *Ancient Geography*, a gulf that lay between the Chersonese of Thrace to the S.E., and a part of the continent to the N.W. It is now called the "gulf of Megarissa."

MELANI MONTES, a chain of mountains, placed by Ptolemy in Arabia Petræa, supposed by Jerome to be those that are called in scripture Sinai and Oreb.

MELANI, ALESSANDRO, in *Biography*, the composer of an opera, which was extremely applauded at Bologna, Florence, and in many other theatres of Italy, in 1697, called "Il Carcicrier di se Hesso."

MELANIPPIDES, a Greek poet and musician, who flourished about the sixtieth olympiad, and whose poetry and music rendered him famous. He had a grandson of the same name, who was likewise a great musician; though Plutarch, in a croaking fit, accuses him of having been one of the first corrupters of the ancient music, by the innovations which he introduced. See TIMOTHEUS.

MELANITE. See GARNET.

MELANIUM, in *Botany*, from μελας, *black* or *dark*, μελανιον being a name for the purple violet. It is applied by Browne, in his History of Jamaica, p. 215, to a small weak Jamaica plant, with a peculiarly disagreeable and pungent smell, which Linnæus referred to LYTHRUM, (see that article,) by the name of *L. Melanium*. Sp. Pl. 641. Swartz. Obs. 193. The author last mentioned says the flowers are purple; and this accounts for the name, for the application of which Browne, as usual, gives no reason.

MELANOGÆTULI, or NIGRITÆ, or *Black Gætulians*, in *Ancient Geography*, a people of Africa, placed by Ptolemy between the mountains Sagapola and Usargala, in a district S.E. of Gætulia Propria, to which it is contiguous, and N. of the river Niger. (See GÆTULIA.) The Melanogætuli were a people without doubt different from the Gætulians, and so considered by Ptolemy, though Cellarius insinuates that they were a tribe of that people. Their complexion not only evinces this fact, but likewise shews, that their progenitors were different from those of the Gætulians. The modern district of Wad-reag, in the province of Constantina, containing a collection of twenty-five villages ranged in a N.E. and S.W. direction, corresponds with a part of the country of the Melanogætuli, according to Dr. Shaw. Our learned traveller likewise supposes, that the country of the Beni-Mezzab, situated 35 leagues to the S. of the mountains of the Ammer, supposed to be part of the Mons Phraræsus of Ptolemy, the large village of Engousah, 30 leagues to the S.W. by W. of Tuggart, the capital of Wad-reag, and the populous city of Wurglah, with their dependencies, even to the banks of the Niger, were included in Melanogætulia. As Ptolemy places the Melanogætuli next to the Pharusii in a southern direction, fixing his Nigritian Ethiopians in a tract lying to the north of the Niger; and as Mela, Pliny, and Strabo give the Nigritæ exactly the same situation with regard to the Pharusii and the Niger, but are quite silent as to the Melanogætuli; it is very probable, that the Melanogætuli and Nigritæ were the same people. If this supposition be admitted, it will appear very credible, that their territories extended to the Niger, and that they had some remarkable places in those parts; since, according to Ptolemy, many towns stood not far from that river, of which the principal were Passide, Saluce, Negira, Thige, Cuphe, Thammdicana, and Vellegia. The most celebrated rivers of this part were the Gir and Niger. If any credit be given to Leo and the African historians, Sabtecha, the son of Cush, first peopled the Sahara, between the mountains of Atlas and Nigritia, and therefore probably Nigritia itself, or at least part of it. From the same author it appears, that the various Nigritian dialects bear an affinity to the Chaldee, Arabic, and Egyptian tongues; and consequently to the Ethiopic, which does not differ widely from them. The Carthaginians had undoubtedly some knowledge of the Nigritæ, since it appears probable from Frontinus, that one part of their army consisted of Nigritian troops. This circumstance will enable us to account for several antique coins with a Negro's or Nigritian's head upon them. The Nigritæ used chariots in their wars, and were armed after the manner of the western Ethiopians with bows and arrows, as we learn from Strabo. According to the same author, the Pharusii, and therefore, probably, the Nigritæ, travelled in caravans through the deserts to Cirta, and kept open a communication with the Maurusii. On these occasions they carried bottles filled with water, tied to their horses' bellies, lest they should perish from thirst in the vast deserts through which they were obliged to traverse. Hence it is undeniably clear, that these Pharusian and Nigritian merchants lived at a great distance from Cirta, and those places of Mauritania to which they resorted; and also that the Negroes or Blacks held an early correspondence with the ancient Mauritanians, Numidians, and Carthaginians. Anc. Un. Hist. vol. xvi. 8vo.

MELANOSCHOENUS, in *Botany*, from μελας, μελανος, *black*, and σχοινος, *a rush*, Mich. Gen. 46. t. 31, is *Schoenus mucronatus* of Linnæus. See SCHOENUS.

MELANO-SYRI, in *Ancient Geography*, a name given to those who inhabited Syria, between the Euphrates and the Mediterranean sea, by way of contradistinction to the *Leuco-Syri*, who lived in Cappadocia, towards the Euxine sea. The former are black Syrians, and the latter white, as their respective appellations import.

MELANTHIUM, in *Botany*, so called by Clayton, from μελας, *black* or *dark*, and ανθος, *a flower*; but the first word is here taken in a wider sense than is usual, even in its application to flowers; for the plant of Clayton, *M. virginicum*, Linn. Sp. Pl. 483, has a dull yellowish, lurid, but not black, hue. This plant is probably a *Veratrum*; but several others, more remarkable for the darkness of their flowers, have been referred to the genus before us, which now rests upon them. It must not be supposed however that any of these is the μελανθιον of the ancient Greeks, for the description in Dioscorides, more particular and expressive than usual, evidently indicates the *Nigella sativa*, the name being applied by a metastasis to the flower, which is white, the seeds, for which the plant was known and cultivated, being intensely black. Sometimes indeed the plant was, for this last reason, called μελανοσπερμον. Our present business is with the Linnæan *Melanthium*, as far as we can define its limits. Linn. Gen. 179. Schreb. 240. Willd. Sp. Pl. v. 2. 266. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 326. Juss. 47. Lamarck Illustr. t. 269. Thunb. Prod. 67. (Wurmbea; Thunb. Nov. Gen. 18. t. 1. Schreb. 239. Willd. Sp. Pl. v. 2. 265. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. ed. 2. v. 2. 325. Lamarck Illustr. t. 270.)—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronariæ*, rather *Tripetaloideæ*, Linn. *Junci*, Juss.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* of six petals, sometimes contracted, sometimes combined, at the base, inferior, ovato-lanceolate, acute, spreading, equal, permanent. *Stam.* Filaments six, thread-shaped, erect, the length of the corolla, more or less attached to it, permanent; anthers globose. *Pist.* Germen superior, nearly globular; styles three, spreading, thread-shaped, the length of the stamens, recurved at the extremity, permanent; stigmas simple. *Peric.* Capsule ovate, with three furrows, three cells, and three valves, crowned with the styles. *Seeds* numerous, roundish.

Ess. Ch. Calyx none. Petals six, equal, bearing the stamens. Styles permanent. Capsule of three cells, with many seeds.

Obs. The sound Linnæan rule, that "the genus should give the character, not the character the genus," induces us to follow Linnæus, and even Thunberg himself, the original establisher of *Wurmbea*, in reducing that genus to *Melanthium*, from which it differs merely in the combination of its petals at their base into an angular tube, a character which, by a comparison of all the species together, will appear of no essential consequence in this case. Mr. Salisbury's *Ornithoglossum*, received into Ait. Hort. Kew. ed. 2. v. 2. 327. (*Melanthium viride* of Linnæus and Thunberg), however alike to many of the species at first sight, does so materially differ, in having the stamens inserted into the receptacle, and, like the styles, deciduous, to say nothing of other characters, that we cannot well retain it here. (See

ORNITHO-

Ornithoglossum.) Neither are we at all certain that fome of the following may not require to be placed elfewhere. *M. letum*, Willd. Sp. Pl. n. 3, is now properly referred to *Helonias*, by Mr. Ker in Curt. Mag. t. 803.

1. M. *fibiricum*. Siberian Graffy Melanthium. Linn. Sp. Pl. 483. (Melanthium; Linn. Am. Acad. v. 2. 349. t. 4. f. 11. Ornithogalum; Gmel. Sib. v. 1. 45. t. 8.)—Flowers panicled. Petals combined at the bafe. Capfule pointed. Leaves linear.—Native of mountainous woods in Siberia, where it was gathered by Gmelin, flowering in July. We have never feen a living fpecimen. The *root* is bulbous, perennial, oblong, white. *Stem* flender but firm, erect, one or two feet high, nearly leaflefs, glaucous when young, terminating in a longifh, fomewhat compound, bracteated *panicle*, of greenifh-white fmall *flowers*, whofe petals are reflexed. *Capfule* half an inch long, erect, ovate, pointed, purplifh, fheathed at the bottom by the combined dilated bafes of the petals, and crowned with the recurved ftyles. It burfts in the furrows, from the top nearly to the bottom.

2. M. *capenfe*. Spotted-flowered Melanthium. Linn. Sp. Pl. 483. Thunb. Prod. 67.—Flowers racemofe. Petals dotted, contracted at their bafe. Leaves ovato-lanceolate, with a broad fheathing bafe—Native of the Cape of Good Hope. *Root* an ovate bulb. *Stem* two or three inches high, with a few broad, fpreading, pointed *leaves*, and a fhort terminal clufter of fpotted *flowers*, whofe ftamens cohere but flightly with the petals. We find no figure of this fpecies.

3. M. *junceum*. Rufh-like Melanthium. Jacq. Ic. Rar. t. 451. Curt. Mag. t. 558. Willd. Sp. Pl. n. 7. (M. triquetrum; Linn. Suppl. 213.)—Leaves linear-awlfhaped, the upper ones dilated and concave at the bafe. Spike zigzag. Petals contracted at the bottom.—Native of the Cape. It flowers in the green-houfe early in the fpring, like other bulbs from the fame country, and indeed refembles an *Ixia* in its fpike of purplifh *flowers*, the bafes of whofe petals are marked with a double violet fpot. The *leaves* are glaucous, rather fucculent, and the uppermoft are remarkable for their tumid or inflated figure, juft above their infertion.

4. M. *ciliatum*. Fringed Melanthium. Linn. Suppl. 213. Thunb. Prod. 67.—Leaves ovate, fpreading, finely fringed with cartilaginous teeth. Spike zigzag. Petals much contracted at the bottom.—Native of the Cape; we find no traces of it in the Englifh gardens. The habit is like an *Orchis*, the lower part of the ftem bearing two or three broad, ovate, fpreading *leaves*, with a fheathing bafe, their edges minutely fringed. *Spike* rather denfe, of many feffile *flowers*, fpreading every way, whofe petals are elliptic-oblong, with a confiderable claw, and appear to be white, minutely ftreaked or dotted with purple or red.

5. M. *fecundum*. Single-ranked Melanthium. Lamarck Dict. v. 4. 28. Illuftr. t. 269. f. 2. Willd. Sp. Pl. n. 8.—Leaves linear. Spike inclined one way. Petals contracted at the bottom, with a tooth at each fide.—Native of the Cape, where it was gathered by Sonnerat and by Bladh. The younger Linnæus confounded it with the laft in his herbarium, and apparently in his Supplement. The prefent however is abundantly diftinguifhed by its narrow erect *leaves*, and efpecially by a remarkable tooth at each fide of the *petals*, juft above their claw or contraction, well obferved by Defrouffeaux in Lamarck. It feems doubtful to us whether the unilateral direction of the *flowers* be not an effect of drying. They are white or blufh-coloured, dotted like the foregoing.

6. M. *indicum*. Indian Melanthium. Linn. Mant. 226.—Leaves linear. Flowers corymbofe. Petals linear-lanceolate, tapering at the bafe.—Sent by Koenig from Pondicherry.

This has much the habit of *Ornithogalum luteum*. The *leaves* are very narrow, erect, and rife above the *ftem*, which bears a fort of leafy or bracteated *corymbus* of a very few upright *flowers*. The narrow and fharp *petals* are of a dark purple, as well as the *ftamens* and *piftil*. We think, with Willdenow, that there is a connection between the filaments and petals, efpecially as there is but a fimple row of fix fcars at the bafe of the ripening germen, after the flower has fallen, which indicates that the ftamens have no feparate infertion there. The *ftyles* are permanent, even on the ripe capfule. Neverthelefs the whole afpect of the plant is fo nearly allied to that of *M. viride*, (Mr. Salifbury's *Ornithogloffum*,) as almoft to fhake our faith in that genus.

7. M. *flavum*. Yellow Melanthium. (M. uniflorum; Jacq. Ic. Rar. t. 450. Coll. v. 4. 100. Curt. Mag. t. 767. Ait. Hort. Kew ed. 2. v. 2. 327. Willd. n. 12. M. æthiopicum; Herb. Linn. Lamarck Dict. v. 4. 29. Tulipa Breyniana; Linn. Sp. Pl. 438. Willd. Sp. Pl. v. 2. 98. Thunb. Prod. 65.)—Leaves linear-lanceolate, fheathing. Flowers fomewhat fpiked. Petals elliptic-lanceolate, tapering at the bafe. Stamens united to the petals more than half way up. Germen and capfule columnar.—Native of the Cape, where it was gathered by Thunberg. It is impoffible to retain the name *uniflorum* for this fpecies, which, as Mr. Ker obferves, is altogether fallacious. We have therefore ventured to tranflate the Englifh appellation, given by him, and adopted by the learned authors of the Hortus Kewenfis. We would have called it *Breynianum* after Linnæus; but the fynonym of Breynius feems very evidently to belong to fomething elfe; we pretend not to fay what. In this difficulty, fenfe is furely preferable to the mere records of confufion and miftake. The *ftem* is from a fpan to a foot high. *Leaves* fpreading, keeled and fheathing at the bafe. *Flowers* from two to fix, in a clofe zigzag fpike; very rarely folitary only. The *petals* are yellow on the upper fide; brownifh crimfon beneath. In the dried fpecimen this laft-mentioned colour runs into minute oblong fpots, which induces a fufpicion that the dotted appearance in fome of the former fpecies, known to us in a dry condition only, may not exift in the frefh flowers. The bafe of each petal in that now under confideration tapers down into a long dark-red claw, to which each *filament*, of the fame colour, is firmly united for three-fourths of its own length. The *germen* is remarkably columnar, with three longitudinal furrows. *Styles* very fhort, thick, and recurved. *Anthers* oblong.

8. M. *eucomoides*. Dwarf Green Melanthium. Jacq. Ic. Rar. t. 450. Curt. Mag. t. 641.—Leaves ovate-oblong, fpreading, fheathing at the bafe. Stalk with few flowers, fhorter than the leaves. Bafe of the petals concave, with a tooth at each fide.—Native of the Cape; rarely feen in England. This is very unlike any of the former, being of a dwarf habit, with feveral broad, fheathing, long, fpreading *leaves*, recurved at their points. Among thefe ftands a fhort *ftalk*, bearing one, two, or three large green *flowers*, of a fingular and not beautiful appearance. The long bafes or claws of the *petals* are rolled in at their fides, and crowned with a pair of broad blunt teeth, analogous to thofe defcribed in our fifth fpecies. *Filaments* united to the claws. *Anthers* oblong, yellow, brown at the back. *Germen* oval, with three deep furrows. *Styles* awl-fhaped, flightly recurved at the top.

9. M. *pumilum*. Little Rigid Melanthium. Forft. Comm. Gött. v. 9. 30. t. 6. Willd. n. 14.—Leaves lanceolate, rigid,

rigid, channelled, ſharp-pointed, bearded at the baſe. Stalk with few flowers, ſhorter than the leaves.—Native of Terra del Fuego. By one of Forſter's ſpecimens in our poſſeſſion, this appears to be a mountain plant, of a dwarf-tufted habit; having numerous, crowded, ſpreading, radical *leaves*, an inch long, ovato-lanceolate, rigid, pungent and rough-edged; channelled above, keeled beneath; their ſheathing baſes denſely inveſted with long, white, ſhining, pellucid hairs. The *flowers* are ſaid to be white; in a dry ſtate they have a purpliſh tinge. They are about three or four, each ſupported on its own ſhort *ſtalk*. *Petals* not contracted at the baſe. *Styles*, according to Willdenow, (from whom we adopt the reference to Forſter,) none; the *ſtigmas* three, rarely ſix.

Willdenow juſtly obſerves that *M. luteum*, Thunb. Jap. 152, is probably diſtinct from *Veratrum luteum* of Linnæus. Having ſeen no ſpecimen, by which we might judge of its genus, we decline admitting it here.

MELANURUS, in *Ichthyology*. See SPARUS *Melanurus*.

MELAONES, a word uſed by certain authors for a black kind of worm found in meadows in the month of May, which, when bruiſed, emits an agreeable ſmell. Some alſo have called a ſmall ſpecies of beetle by the ſame name.

MELAPARA, in *Geography*, a town of Bengal; 10 miles E.N.E. of Dacca.

MELAS, in *Ancient Geography*, the name of ſeveral rivers; *e. g.* a river of the Peloponneſus, in Achaia:—a river of Bœotia, which had its ſource ſeven ſtadia from Orchomené, and diſcharged itſelf into the lake Cephiſus:—a river of Theſſaly, near Heraclea:—a river of Mygdonia:—a river of Thrace:—a river of Aſia, whoſe ſource was near the town of Cæſarea ad Argæum:—a river of Aſia, in Pamphylia:—a river of Aſia, in Armenia Minor.

MELAS, μελας, in *Medicine*, ſignifying literally *black*, is a term applied by the ancients to a diſeaſe of the ſkin, which appears to be a variety of the ſcaly lepra; differing principally in the colour of the eruption from the more common form, which is white, and which was called *Alphos*, or *Leuce*. (See theſe articles.) The *leuce*, however, as we have there ſhewn, in ſtrictneſs, ought not to be confounded with *alphos*, or put under the ſame genus with it and the *melas*; ſince all the ancients, even Celſus, who has ranked all three under the head of *vitiligo*, diſtinctly pointed out the eſſential difference of the *leuce*. See Celſus, lib. v. cap. 27. ſect. 19. See alſo LEPROSY.

MELASICTERUS, from μελας, *black*, and ικτερος, *icterus*, the *jaundice*, a term which has been applied by ſome writers to that ſevere and inveterate degree of jaundice, which has been alſo termed in Engliſh the *black jaundice*. (See JAUNDICE.) Sauvages, Noſol. Method. claſs ix. genus 12.

MELASMA, in *Botany*, ſo named by Bergius, from μελας, *black*, apparently becauſe the herb aſſumes that colour in drying. Thunberg, who likewiſe eſtabliſhed it as a genus, called it *Nigrina*, for the ſame reaſon. The younger Linnæus referred it to GERARDIA (ſee that article); to which Thunberg, in his Prodromus 106, accedes, and the plant ſtands there, as well as in Willd. Sp. Pl. v. 3. 222, under the name of *Gerardia Nigrina*. (Melaſma ſcabrum; Berg. Cap. 162. t. 3. f. 4.)—Herb rough. Leaves lanceolate; ſerrated in their lower part. Stem ſquare.—Native of the Cape of Good Hope. The *ſtem* is herbaceous, above a foot high, leafy, ſomewhat branched. *Leaves* oppoſite, narrow, about two inches long, rough on both ſides, with prominent points. *Flowers* axillary and terminal, on long ſtalks, drooping, large. Nothing is recorded concerning their colour. Every part of the dried plant is as black as ink.

MELASMA, (from μελας, *black*), in *Surgery*, a black and dark blue, or livid, diſcolouration of the ſkin, more commonly termed by ſurgeons an *ecchymoſis*; which ſee.

MELASPHÆRULA, in *Botany*, ſo denominated by Mr. Gawler, now Ker, who firſt eſtabliſhed the genus, from μελας, *black*, and σφαιρα, *a ball*, in alluſion to the little black and ſhining globular bulbs, ſaid to be produced at the ramifications of the ſtem, as in ſeveral lilies, the *Dentaria bulbifera*, *Saxifraga bulbifera*, and others. Theſe however have not been obſerved on the cultivated *Melaſphærula* in England or France, but Jacquin delineates them. Ker in Sims and Kon. Ann. of Bot. v. 1. 231. Curt. Mag. v. 17. 615. Ait. Hort. Kew. ed. 2. v. 1. 103. (Diaſia; Decand. in Bulletin des Sciences, n. 80. Brumaire an. 12.)—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Enſatæ*, Linn. *Irides*, Juſſ.

Gen. Ch. *Cal.* Spatha inferior, ſhorter than the corolla, of two oblong, acute, permanent valves; the outermoſt broadeſt. *Cor.* of one petal, ſuperior; tube none; limb irregular, two-lipped, ſomewhat bell-ſhaped, divided to the bottom into ſix ovate, briſtle-pointed, ſpreading ſegments, the three lower ones moſt coloured, and rather the ſmalleſt. *Stam.* Filaments three, cloſe together, ſhorter than the corolla, and aſcending under the middle ſegment of its upper lip, recurved at the ſummit; anthers oblong, incumbent. *Piſt.* Germen inferior, three-lobed, depreſſed; ſtyle thread-ſhaped, of the length and ſituation of the ſtamens; ſtigmas three, ſpreading, ſimple, bluntiſh. *Peric.* Capſule three-lobed, depreſſed, thin, of three cells and three valves, opening at the upper ſide. *Seeds* few, globoſe, without wing or border.

Eſſ. Ch. Spatha of two valves. Corolla two-lipped, in ſix deep, nearly equal, briſtle-pointed ſegments; without any tube. Stigmas three, recurved. Capſule three-lobed. Seeds globoſe.

M. *graminea*. Graſs-leaved Melaſphærula. Curt. Mag. t. 615. (Diaſia iridifolia; Redout. Liliac. t. 54. Gladiolus gramineus; Linn. Suppl. 95, excluding the ſynonyms. Willd. Sp. Pl. v. 1. 221. Jacq. Ic. Rar. t. 236. Andr. Repoſ. t. 62.)—Gathered by Sparrmann and Thunberg at the Cape of Good Hope. Mr. Maſſon ſent it to Kew in 1787, where it bloſſoms in the green-houſe during moſt part of the year. The *root* is a ſmall, coated, roundiſh bulb. *Stem* near two feet high, ſlender and rigid like that of a graſs. The leaves alſo are of a graſſy habit, pale green, long and narrow. *Flowers* numerous, in a lax and ſlender panicle, ſcentleſs, ſmall, compared with many of the ſame tribe. *Spatha* green, with a filmy edge. *Corolla* of a pale greeniſh-yellow, each ſegment marked with a purpliſh-brown, central line, or rib, of which thoſe in the three lower ſegments are broadeſt and moſt conſpicuous, evincing the natural irregularity of the flower. The *ſeeds* are brown.

No other ſpecies is known. Redouté diſtinguiſhes this, after Decandolle, into two, according to the various length and uprightneſs of the foliage, but, as it ſeems to us, without ſufficient reaſon.

MELASSES. See MOLASSES.

MELASSO, a town of Aſiatic Turkey, in Natolia, anciently called "Mylaſa," or "Mylaſſa." It is ſituated on a fertile plain near a mountain, which furniſhes a great quantity of fine white marble. It had formerly a temple dedicated to Auguſtus Cæſar, with twenty-two columns, ſix of which were in front; and it was adorned with ſo many temples and public buildings, that a certain muſician, on entering the αγορα, or market-place, to make a proclamation, on, used the words ακουετε ναοι, hear ye temples, instead of ακουετε λαοι, hear ye people. Under the Romans it was a free city. It is now a large place, containing a great number of houses, though they are mean. The air is accounted bad, and scorpions abound; 80 miles S. of Smyrna. N. lat. 37° 10'. E. long. 27° 40'.

MELASTOMA, in *Botany*, a very extensive tropical genus of plants, most remarkable for the transcendent beauty and peculiarity of its foliage. The name was composed by John Burmann, of μελας, *black*, and στομα, *the mouth*; being synonimous with the Portuguese appellation of one of the Ceylon species, *Bocca preto*, or Black Mouth, which arose from the effect of the fruit upon the lips of those who eat it. Some of the West Indian species are known by the name of American Gooseberries.—Burm. Zeyl. 156. Linn. Gen. 217. Schreb. 293. Willd. Sp. Pl. v. 2. 581. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 45. Juss. 329. Lamarck Dict. v. 4. 31. Illustr. t. 361. Gærtn. t. 126. Aubl. Guian. 402—437. Swartz. Ind. Occ. 764—822. (Acinodendron; Linn. Gen. ed. 1. 129. Tococa; Aubl. Guian. 437. Fothergilla; ibid. 440. Mayeta; ibid. 443.)—Class and order, *Decandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Melastomæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, four or five-cleft, swelling at the base, permanent. *Cor.* Petals four or five, roundish, inserted into the rim of the calyx. *Stam.* Filaments eight or ten, short, inserted into the calyx; anthers very long, terminal, somewhat curved, of one or two cells, opening by an oblique terminal pore, and often accompanied by a pair of small spreading scales at the base. *Pist.* Germen roundish, in the bottom of the calyx; style thread-shaped, declining; stigma blunt or capitate. *Peric.* Berry of two to five cells, roundish, coated with the body of the calyx, and crowned with its permanent annular rim. *Seeds* very numerous, imbedded in pulp.

Ess. Ch. Calyx four or five-cleft, bell-shaped. Petals as many as the segments of the calyx, inserted, with the stamens, into its rim. Anthers beaked, opening at the tip. Berry of five cells, invested with the calyx.

Only fifteen species of this genus are defined in the 14th edition of the *Systema Vegetabilium* of Linnæus, but the discoveries of Swartz, and of various correspondents of sir Joseph Banks, in the West Indies, and of Aublet in Guiana and Cayenne, have very greatly increased that number, so that Willdenow describes eighty-five, notwithstanding his having referred some species of the above authors to *Rhexia.* We are possessed of a few that do not appear in Willdenow's list. The whole are distributed into various sections, distinguished by the number of stamens, which differ in different species from ten to eight or twelve; and the petals and segments of the calyx also from five to four or six. Subordinate characters of each section depend on the number and connection of the longitudinal ribs of the leaves, which, throughout the whole genus, are very remarkable, and in some form, together with the transverse veins, the most elegant appearance imaginable. The leaves in all are opposite and simple, their two sides generally different in colour and pubescence, the under one being often downy, rusty, or silky. Stem shrubby. Flowers numerous, axillary, or more generally terminal; their petals rarely yellow, usually red, purple, or whitish; with, for the most part, yellow very handsome anthers. We shall select examples of each section, marking the species by Willdenow's numbers.

Sect. 1. *Stamens* twelve. Three species in Willdenow.

1. M. *calyptrata.* Vahl. Eclog. v. 1. 40. Lamarck Dict. v. 4. 51?—Leaves elliptic-lanceolate, tapering, three-ribbed, smooth, slightly and minutely toothed. Flowers panicled.—Native of the island of Montserrat.—"*Panicle* terminal, erect, four inches long; its branches spreading, the lowermost four together, the rest opposite, smooth, their ultimate divisions divaricated, three-flowered. *Flowers* stalked, covered with an acute conical lid, separating all round and deciduous. *Calyx* abrupt, the size of a coriander seed. *Petals* yellow." *Vahl.*—The late Dr. Dancer sent us from Jamaica a specimen which answers to the above characters, except that the *flowers* seem fewer and larger. The teeth of the *calyx* are firmly united into a thick coriaceous conical lid, like that of an *Eucalyptus,* (see that article), which sometimes splits at the top, but more generally falls off entire, by an irregular circular separation from the body of the calyx. Within this are the *petals.* The *fruit* is crowned with a very narrow annular rim, quite distinct from the calyx.

3. M. *patens.* Swartz. Ind. Occ. 791.—Leaves with five or seven ribs, heart-shaped, hairy, somewhat toothed. Cluster terminal, spreading, bristly. Stamens twelve.—Native of the more lofty mountains of Jamaica, flowering in summer. The inhabitants call it the American Gooseberry. The *fruit* is sweet, but wants spirit. The *flowers* have rarely only ten *stamens.* It is a *shrub* eight or ten feet high, clothed with prominent, bristly, brownish-red hairs, and the branches are dark purple. *Leaves* varying in length from three to six inches, broad; green and bristly above; pale and downy beneath: ribs five or seven, besides the slender marginal ones, connected by a profusion of reticulated veins. *Footstalks* two or three inches long, bristly. *Clusters* three-forked, very bristly, with a pair of small leaves at each subdivision. *Flowers* large, with linear, bristly, elongated calyx-teeth, and whitish or flesh-coloured petals.

Section 2. *Stamens ten; leaves with three separate ribs.* Eighteen species in Willdenow.

5. M. *rigida.* Swartz. Ind. Occ. 768.—Leaves three-ribbed, minutely toothed, rigid, ovate, somewhat heart-shaped; roughish beneath. Clusters terminal, panicled, rough with dense rusty down.—Native of the Blue mountains of Jamaica; communicated by Dr. Dancer. A *shrub* 10 or 12 feet high; its *branches* obtusely quadrangular, compressed, rough at the extremities with dense, short, dark, rusty, somewhat starry, pubescence. *Leaves* from three to six inches long, on long rusty stalks, ovate, or slightly heart-shaped, rigid but brittle, pointed; smooth above; roughish, but of the same green colour, beneath; with three distant ribs, besides the marginal ones, and many parallel transverse veins. *Panicle* long, many-flowered, repeatedly three-forked, rusty. *Flowers* small, with white petals, each *calyx* subtended by a pair of long, awl-shaped, rusty, deciduous *bracteas.*

7. M. *montana.* Swartz. Ind. Occ. 766.—Leaves three-ribbed, very slightly toothed, nearly smooth. Cluster terminal; its branches deeply three-cleft, spreading. Petals obtuse. Calyx abrupt, with a deciduous lid.—Communicated by Dr. Swartz from the lofty mountains in the southern part of Jamaica. The *leaves, stalks,* and *calyx* are, in the dried plant at least, of a light yellowish-green, and every part is nearly, if not quite, smooth. *Flowers* small, white, their calyx-teeth combining to form a lid, as in the first species. The upper surface of the *leaves* is minutely granulated. Their lateral ribs are united, for a short space, to the middle one, so that they strictly come under the denomination of triply-ribbed. The marginal ones are distinct from the very bottom.

10. M. *aspera.* Linn. Sp. Pl. 560. (M. foliis lanceolatis trinerviis scabris; Linn. Zeyl. 76. n. 172. M. scabra trinervia;

trinervia; Burm. Zeyl. 154. t. 72.)—Leaves ovato-lanceolate, three-ribbed, entire, rough with depreffed briftles. Flowers in leafy clufters.—Native of Ceylon. We have a fpecimen from fir G. Staunton which anfwers well to Hermann's figure and defcription. Thefe were mif-applied by Linnæus to his *octandra*, as is well remarked by Retzius in his *fafc.* 4. 25. In the Linnæan herbarium a fpecimen occurs marked *afpera*, which is not an original one, nor, in fact, different from *malabathrica* hereafter mentioned, except that the lateral ribs of the leaves are very fmall. *Katou Kadali*, Hort. Malab. v. 4. 91. t. 43, quoted for the prefent fpecies, has ftrongly five-ribbed leaves, and numerous corymbofe flowers, with an extremely hifpid calyx. We cannot think it belongs here, and ftill lefs the *Fragarius ruber* of Rumph. Amboin. v. 4. 135. t. 71, whofe flowers are defcribed as fmall and white. Thofe of *M. afpera* are acknowledged on all hands to be large and purple. The Eaft Indian *Melaftomæ* have not yet been carefully ftudied on the fpot, by any accurate botanift, and the fynonyms of this in particular have been much confufed.—See *M. cyanoides*, hereafter defcribed, a fpecies to be introduced between Willdenow's n. 56 and 57.

12. M. *ftrigofa*. Linn. Suppl. 236; excluding the fynonym.—Leaves ovate, three-ribbed, very briftly, entire. Flowers terminal, folitary. Calyx very briftly; its fegments broad and triangular.—Sent by Mutis from New Grenada. This is a much-branched *fhrub*, whofe numerous *leaves* are ovate, ftalked, about three-fourths of an inch long; paler, with three ribs very prominent, beneath. Every part is clothed with depreffed yellow briftles. *Flowers* large, terminal, folitary, purple, their petals fringed with briftles; and the *calyx* is peculiarly hifpid, with broad, fhort, triangular fegments. It is a very handfome and remarkable fpecies.

14. M. *velutina*. Willd. (M. holofericea; Herb. Linn Swartz. Obf. 176.)—Leaves three-ribbed, ovate, acute, entire, feffile, clothed on both fides with filky briftles. Clufter terminal, four-ranked; its branches cloven. Stem acutely quadrangular.—Native of Brafil, where it was gathered by father Panegai, and fent by Arduino to Linnæus; as well as by fir G. Staunton and fir J. Banks. We know no authority for its being found in Jamaica.—The *leaves* are from one to two inches long, feffile, remarkable for their denfe filky briftly clothing. They have three principal ribs, with occafionally two flighter ones near the margin, towards the bafe. *Flowers* large and handfome, purple, with a very filky calyx, and ten long ftamens.—This fpecies is totally diftinct from the original Linnæan *holofericea*, of which we fhall fpeak hereafter. See n. 53.

14—15. M. *cuprea*.—Leaves three-ribbed, elliptic-ovate, pointed, entire, on fhort ftalks; nearly fmooth above; clothed with denfe ftarry down beneath. Panicle terminal, thrice compound, with radiating branches.—Gathered in the Caraccas, by J. Mærter, M. D. The *branches*, *ftalks*, *germen*, and back of the *leaves*, are all denfely clothed with fine ftarry hairs, which, in a dried ftate at leaft, are of a rich copper-coloured brown. A portion of the fame is feen on the upper furface of each *leaf*, efpecially on the ribs. The fegments of the *calyx* are fmooth. *Flowers* very fmall and numerous, cluftered, and compofing a fpreading, very compound *panicle*, whofe branches fpread in a radiating manner, many from one point, the lower ones at each ramification being the fhorteft. *Petals* not expanded in our fpecimen.—This fhould be placed between the 14th and 15th fpecies of Willdenow. We can refer it to none that he enumerates.

14—15. M. *fquamulofa*.—Leaves three-ribbed, elliptical, obtufe, entire; fmooth above; hoary beneath. Panicles terminal, compact. Calyx angular, minutely fcaly.—Sent from New Grenada by Mutis to Linnæus. The *ftem* is woody. *Leaves* on fhort thick ftalks, rigid, elliptical, fcarcely two inches long, obtufe, entire, with three diftinct ribs, and numerous fine tranfverfe veins. The upper fide is green, quite fmooth and rather fhining; the under hoary, with very clofe, fomewhat fcaly, pubefcence. *Panicles* terminal, compound, compact, about three inches long, many-flowered. *Calyx* turbinate, with ten ribs, and five broad fhort teeth, covered all over with clofe-preffed fcurfy fcales. *Petals* five, fmall, round, apparently yellow. *Berry* fmall, furrowed, hoary. Sometimes the *flowers* appear to be fix-cleft.—This may ftand next to our *cuprea*, though it has no particular likenefs or affinity to that, or any other of this fecond fection, being moft allied to *liguftrina*, another new fpecies hereafter defcribed, from the fame country.

20. M. *trinervia*. Swartz. Ind. Occ. 774.—Leaves three-ribbed, fmoothifh, elliptical, acute at both ends; the lateral ribs near the margin. Spikes long, axillary, in pairs. Flowers oppofite or whorled.—Native of mountains in Jamaica. Introduced in 1793 into the ftoves at Kew, where it blooms in July. The *leaves* are a fpan long, ftalked, thin and pliant, of a broad, elliptical form, pointed at each end, pale beneath, with flightly downy veins. Thefe *leaves* are peculiar for having the fide ribs almoft marginal, and very remote from the midrib, with which however they are connected by numerous tranfverfe ribs, and reticulated veins. The inflorefcence is fo incorrectly defcribed, that had we not authentic fpecimens, we could not have been certain of our plant. The *flowers* are fmall, numerous, in long downy fpikes, two of which ftand together in the forks of the branches, and are perhaps originally terminal, as Dr. Swartz defcribes, but the branch is foon extended on each fide beyond them; neither are they *racemi*, for the *flowers* are perfectly feffile, in diftant pairs, or fometimes whorls.

21. M. *repens*. Willd. n. 21. Lamarck Illuftr. t. 361. f. 2.—"Leaves obovate, fmooth, three-ribbed, nearly entire. Flowers folitary, terminal. Stem creeping."—This, which is faid to come from China, does not appear to us different from the *octandra* of Linnæus, which varies in the number of parts in the flower, and will be hereafter defcribed. We are at leaft certain that the fynonyms of Ofbeck and Retzius, cited here by Willdenow, belong to the real *octandra*.

Section 3. *Stamens ten*; *leaves with three ribs combined at the bafe*.

23. M. *parviflora*. Aubl. Guian. 433. t. 171.—Leaves ovato-lanceolate, acute at each end, obfcurely toothed, triple-ribbed, fmooth. Panicle terminal, repeatedly three-forked.—Found by Aublet growing in moift fituations in Cayenne and Guiana, where the inhabitants call it *tincta*, after the Portuguefe, and ufe it in decoction to dye black. The *ftems* are upright, fhrubby, feven or eight feet high. *Leaves* a fpan long, pliant and quite fmooth, green on both fides, but paler beneath, on fmooth *footftalks*, fcarcely an inch in length. They have three principal ribs, which in Aublet's fpecimen unite into one a little above the bafe, at not more than half the diftance expreffed in his plate. There are befides, as ufual, a pair of much flighter marginal ribs, diftinct to the bottom of the leaf. A large, very compound, three-forked *panicle*, of fmall white *flowers*, terminates each branch; but it fometimes becomes lateral by the elongation of the branch beyond. The *berries* are fmooth, fcarcely fo big as a peppercorn, and of a blueifh colour. The plant bears flowers and fruit in April.

25. M. *arborefcens*. Aubl. Guian. 420. t. 163.—Leaves roundifh-

roundish-ovate, acute, entire, triple-ribbed, smooth. Corymbs lateral. Petals divided at the base.—Native of woods in Guiana. A *tree* 60 feet high, with very broad ovate smooth entire *leaves*, rather opaque and paler beneath, four or five inches long. Their three central ribs are united for half an inch above the base; two lateral ones spring from the bottom; and there is also a pair of very slight marginal ones, not expressed in the plate. The *flowers* are white, produced in lateral bracteated *corymbs*, from the sides of the branches, much below the foliage. The *petals* are described by Aublet with divided or double claws. *Berry* as big as a small medlar, yellow, sweetish, and eatable, known by the name of *mêle* among the colonists. It ripens in November.—Willdenow justly points out the near resemblance of this plant to the Linnæan *M. grossularioides*, a species we have not seen, any more than himself, but its *leaves* are said to be toothed and pointed.

27—28. M. *ligustrina*. Leaves triple-ribbed, ovate, obtuse, entire, quite smooth. Panicles terminal, compact. Calyx hemispherical, furrowed, smooth.—Sent from New Granada, by Mutis to Linnæus. The *stem* and *branches* are woody, and, like the whole plant, perfectly smooth. *Leaves* stalked, an inch long, broadish-ovate, obtuse, entire, with three strong ribs united for a short distance from the base; the transverse veins are very slender, and the marginal ribs scarcely discernible. The upper surface is dark green, and polished; under paler and opaque, with a yellowish tinge. *Flowers* in compound clusters or panicles like those of Privet. *Calyx* short and hemispherical, most deeply furrowed in the upper part, quite smooth, with short, broad, blunt teeth. *Petals* small, roundish, white or purplish. *Stamens* short, with broad blunt anthers. *Style* obtuse. *Stigma* concave. *Berry* small, yellowish. All the *flowers* seem five-cleft. This is most akin to our *M. squamulosa*, described in the second section, though abundantly distinct. Linnæus had determined the genus of both, but left them undescribed.

Section 4. *Stamens ten; leaves with five combined ribs.*

28. M. *agrestis*. Aubl. Guian. 425. t. 166.—Very hairy. Leaves ovate, long-pointed, crenate, fringed, quintuple-ribbed. Corymbs axillary and terminal, spreading.—Native of banks of rivers, and about old walls, in Cayenne. *Aublet.* The specific name therefore must allude to its roughness of habit, not to its place of growth. The dense rusty-red spreading hairs, which clothe the *branches*, *flower-stalks*, *footstalks*, ribs and margins of the *leaves*, give the plant a tawny hispid aspect. The *leaves* are truly ovate, pointed, very neatly and closely crenate, about three inches long; their ribs disposed exactly as in the *arborescens* last described, so that both species ought to stand in the same section, whichever that may be. Aublet's figure is by no means correct in this point, according to his own specimen, and has missed Willdenow.

29. M. *scandens*. Aubl. t. 172. is more correctly quintuple-ribbed, as that figure expresses; but yet not in so striking a manner as some following species.

30. M. *alata*. Aubl. Guian. 410. t. 158.—Leaves elliptic-oblong, acute at each end, entire, quintuple-ribbed; rough above; downy beneath. Stem winged.—Native of uncultivated ground in Guiana and Cayenne, flowering in September, and fruiting a month or two afterward. The *stems* are six or seven feet high, remarkable for their four membranous wings. *Leaves* sessile, seven or eight inches long and about half as wide, much elongated at each end; rough above; paler and clothed with soft tufted down beneath. They have two pair of ribs, branching at wide intervals from the central one, besides a slight, nearly marginal, nerve. *Panicle* terminal, large, with square, partly winged, stalks. *Flowers* in dense heads, small, whitish. *Berry* red, the size of a gooseberry, not very succulent. A decoction of the leaves is used to wash foul ulcers.

30—31. M. *nervosa*.—Leaves elliptic-oblong, acute at each end, slightly crenate, quintuple-ribbed; rather hairy on both sides. Spikes hairy, whorled.—Native of Jamaica. A specimen with the above name was given to the younger Linnæus from the Banksian herbarium. It was gathered by a man who deceived his employers, by pretending to have collected many of his plants at the isthmus of Darien; whereas it afterwards appeared he went no further than the West India islands. Hence some of his discoveries, being marked with a wrong place of growth, were not admitted by Dr. Swartz, (unless he had found them himself,) into his West Indian Flora. Such appears to be the case with the present *Melastoma*, which we cannot refer to any that is described. Its *leaves* agree much in size, form and ribs, with the *alata* last described; but they are crenate, and clothed with simple and longer hairs, especially the ribs. The *stem* is round, bristly, not winged. *Flowers* in sessile remote whorls, composing a long, terminal, hairy spike.

Section 5. *Stamens ten; leaves with at least five separate ribs.*

32. M. *hirta*. Linn. Sp. Pl. 559, excluding the synonyms of Plumier and Sloane. Swartz. Obs. 175. (M. n. 4; Browne Jam. 219. Arbuscula Jamaicensis quinquenervis minutissimè dentatis foliis et caule pubescentibus, flosculis ex sinu foliorum gemellis; Pluk. Almagest. 40. t. 264. f. 1.)—Leaves ovate, pointed, crenate, five-ribbed, hairy. Flowers axillary, somewhat corymbose, bristly as well as the branches.—Native of Brasil, as also of Jamaica. We have a specimen from Browne, nor can we account for the omission of this species in Swartz's Flora, as that author likewise mentions in his *Observationes* its growing on the woody hills of Jamaica, flowering in autumn and spring. The *stem* is shrubby, six feet high, the younger *branches* very hispid, as are the *footstalks*, *flower-stalks*, *calyx*, and both sides of the *leaves*, especially the under. All the pubescence is of a rusty hue. The *leaves* are broadly ovate, not at all lanceolate, with five distinct ribs, besides a pair scarcely discernible near the margin, towards the base. The *flowers* are white, few together, axillary and corymbose; sometimes said to be six-cleft.

34. M. *Acinodendron*. Linn. Sp. Pl. 558. Swartz. Obs. 174. (Christophoriana americana, malabathri foliis acuminatis, nervosis, dentatis; Pluk. Phyt. t. 159. f. 1.)—Leaves ovate, pointed, five-ribbed, finely toothed, slightly hairy. Panicle terminal, compound, three-forked, roughish. Flowers somewhat capitate.—Native of Surinam. *Baker. Herb. Banks.* Dr. Swartz remarks that this is an obscure species, the synonyms of which are much confounded. The Linnæan herbarium throws no light upon it, but we have received from sir J. Banks, under the name of *M. aurea*, which is very well suited to the colour of the dried leaves, a Surinam specimen, that indubitably accords with Plukenet's figure, which Linnæus commends; and as our specimen will not agree with any other described *Melastoma*, we refer it to the present, omitting all the synonyms as doubtful, except the above. The *branches* are smooth, slightly quadrangular upwards. *Leaves* about three inches long, on rather short hairy stalks, (the only character not expressed by Plukenet,) ovate, neatly toothed, with a short taper point, and five ribs connected by numerous transverse parallel veins. There is a very slight marginal rib near the base. A few golden hairs are sprinkled over the upper surface, and on the ribs of the lower. *Panicle* large and spreading, repeatedly three-forked, roughish with scattered stellated down. *Flowers*

uſually two or three together, ſeſſile, with a pair of *bracteas,* at the end of each ſtalk of the panicle. *Calyx* ſmooth, turbinate. *Petals* five, apparently white or yellowiſh, obovate.

35. M. *cymoſa.* Schrad. Sert. Hannov. 18. t. 8. Vent. Malmaiſ. t. 14. (M. corymboſa; Ait. Hort. Kew. ed. 2. v. 3. 46?)—Leaves ovate, ſomewhat heart-ſhaped, pointed, ſeven-ribbed, ſomewhat hairy, with minute briſtly ſerratures. Cyme terminal. Segments of the calyx triangular.—Native of South America according to Schrader; and, if we are right in the citation of Hort. Kew., of Sierra Leone alſo. It is not probable that ſo fine a plant, for many years paſt frequently ſeen flowering in the Engliſh ſtoves, ſhould not be included in that rich catalogue, and it anſwers moſt preciſely to the character there given under the name of *corymboſa,* except that the flowers are really cymoſe. We received a ſpecimen in 1803, from the botanic garden at Liverpool, with the appellation of *M. purpurea,* under which it ſtands in the catalogue of that garden, p. 250. The *ſtems* are erect, about two feet high, ſucculent, herbaceous, ſcarcely ſhrubby. *Leaves* two or three inches long, on longiſh ſtalks, tender, of a broad, ovate, pointed figure, very ſlightly cordate at the baſe, fringed with minute briſtly teeth directed forwards. The ribs are ſeven, beſides a minute marginal pair at the baſe. Both ſides are roughiſh with minute hairs; the under one paleſt, and moſt poliſhed. *Flowers* ſeveral, roſe-coloured, in a terminal, rather drooping, ſlightly downy cyme. There are five yellow abortive anthers; the five perfect ones are purpliſh.

37. M. *elegans,* beautiful as it appears in Aublet's t. 167, is in every reſpect ſo like *hirta,* ſee n. 32, except the deeper and double crenatures of the *leaves,* that we are perſuaded it is but a variety of that ſpecies. There is no difference in the *infloreſcence* or *flowers.*

40. M. *Maieta.* Lamarck Dict. v. 4. 34. (Maieta guianenſis; Aubl. Guian. 443. t. 176.)—Leaves elliptical, pointed, five-ribbed, minutely crenate, hairy, inflated at the baſe. Flowers axillary, ſolitary, ſeſſile.—Found by Aublet in Guiana, on the banks of a rivulet fifty miles from the ſea-coaſt, flowering and fruiting in November. It is a *ſhrub* two or three feet high, the branches and foliage rough with briſtly, prominent, ruſty hairs. *Leaves* oppoſite, but very unequal in ſize, elliptical with a taper point and five ribs, without any at the margin beſides. The larger *leaf* of each pair is from three to five inches long, and diſtinguiſhed by a bladder-like ſwelling, of two cells, at the baſe, moſt prominent at the upper ſide; the ſmaller *leaf* is from one and a half to two inches long, and is uſually deſtitute of any ſuch bladder. The *flowers* are white, axillary, and ſolitary, bracteated at their baſe. It is difficult to imagine what led Aublet to diſtinguiſh this, as a genus, from *Melaſtoma,* to which it has not the ſlighteſt pretenſions. The germen in the flower is indeed apparently ſuperior, and diſtinct from the body of the calyx; but ſuch is the caſe in many *Melaſtomæ,* though thoſe parts unite into a pulpy maſs as the fruit ripens.

41. M. *heterophylla.* Lamarck Dict. v. 4. 34; and

42. M. *phyſiphora.* (Tococa guianenſis; Aubl. 438. t. 174.) agree with the laſt in having a bladdery appendage to the baſe of the larger *leaves,* or, in the latter inſtance, to their *footſtalks.*

49. M. *groſſa.* Linn. Suppl. 236.—Leaves ſomewhat heart-ſhaped, five-ribbed, entire, very rough. Flowers terminal, corymboſe. Petals briſtly at the back.—Sent by Mutis from New Granada. This very magnificent ſpecies is diſtinguiſhed by its coriaceous and briſtly appearance. The *leaves* are ſcarcely two inches long, about one broad, with five ſtrong ribs, and numerous cloſe tranſverſe veins, clothed very denſely on both ſides, with innumerable, minute, rigid, curved briſtles; paler beneath. The *branches* and *ſtalks* are all equally hiſpid, and of a ruſty hue. *Flowers* very large, purple, about five or ſix in a terminal corymboſe head. Segments of the *calyx* long and lanceolate. *Petals* obovate, above an inch long, clothed at the back, like the *calyx,* with rigid upright briſtles.

50. M. *malabathrica.* Linn. Sp. Pl. 559. Curt. Mag. t. 529?) M. foliis lanceolato-ovatis ſcabris quinquenerviis; Linn. Zeyl. 76. n. 171. M. quinquenervia hirta major, capitulis ſericeis villoſis; Burm. Zeyl. 155. t. 73. Kadali; Rheede Malab. v. 4. 87. t. 42. Fragarius niger; Rumph. Amb. v. 4. 137. t. 72.)—Leaves elliptic-lanceolate, five-ribbed, entire, rough with depreſſed briſtles. Flowers terminal, corymboſe. Calyx clothed with fringed imbricated ſcales.—Native of the Eaſt Indies. It is ſaid to have been given to Kew garden by ſir G. Staunton in 1795. We quote the Botanical Magazine with doubt, becauſe the figure is unfortunately ſo contrived as not to ſhew the *calyx,* a moſt important part in this caſe; neither does the form of the *leaves,* or the ſituation of their lateral ribs, preciſely agree with our wild ſpecimens. Of the other ſynonyms we have no doubt. Burmann, whoſe remarks on this plant are very good, obſerves that the calyx is drawn ſmooth in Rheede's figure, though deſcribed rough. Rumphius moſt happily compares it to the calyx of *Centaurea Cyanus.* It is in fact clothed with fine ſharp-pointed fringed ſcales, ſuch as we have remarked in no other ſpecies. The *petals* are large and purple, ſmooth on both ſides, but fringed with briſtles. The young *branches, ſtalks,* and ribs of the *leaves,* are ſcaly in a degree like the *calyx.* Sometimes the lateral ribs are ſo ſmall and ſlender as to be ſcarcely diſcernible. A ſpecimen ſo circumſtanced is in the Linnæan herbarium marked *aſpera;* ſee n. 10.

50—51. M. *granuloſa.* Lamarck Dict. v. 4. 44.—Leaves ovato-lanceolate, five-ribbed, entire; rough above with cloſe-preſſed briſtles; downy beneath. Cluſter with corymboſe branches. Calyx ſilky. Stem winged.—Gathered by Commerſon in Braſil, and given by Thouin to the younger Linnæus. A magnificent ſpecies, with *leaves* five or ſix inches long, whoſe outermoſt ribs are united at the baſe to the next. Their upper ſurface is ſo granulated, as it were, with cloſe-preſſed briſtles, as to look like the ſurface of a ſtrawberry. The *ſtem* is briſtly, nearly in like manner, and has four membranous wings. *Flowers* purple, large, and handſome, in a compound forked cluſter. *Calyx* denſely covered with ſilky hairs. This *ſhrub* is about ten feet high.

53. M. *albicans.* Swartz. Ind. Occ. 786. (M. holoſericea; Linn. Sp. Pl. 559. Willd. n. 13. Arbor racemoſa braſiliana, foliis malabathri; Breyn. Cent. 1. 3. t. 2. 4.)—Leaves ovate, acute, five-ribbed, entire; poliſhed and naked above; ruſty-white with cottony down beneath. Cluſters terminal, cottony, with cymoſe branches. Flowers ſeſſile.—Native of Braſil and of Jamaica. A *ſhrub* ſix or eight feet high, with hoary *branches,* which are ſlightly angular. *Leaves* on ſhort, thick, hoary ſtalks, elliptic-ovate, acute, three or four inches long, very ſlightly heart-ſhaped at the baſe; perfectly ſmooth and highly poliſhed above, ſo as to look, when dried, like black Spaniſh leather, as Breynius very happily remarks; on the under ſide they are entirely clothed with denſe ſoft cottony down, white with a ruſty tinge, and have five ſtrong ribs, all united at a very ſmall diſtance above the baſe. The *cluſters* are compoſed of oppoſite forked or cymoſe branches. The *flowers* are ſeſſile, ſmall, with a cottony *calyx* and white *petals.*

About this species there has been great confusion. It is unquestionably the original *holosericea* of Linnæus, (admirably described and figured by Breynius,) but not that which he afterwards called so in his herbarium, and which Dr. Swartz described in his *Obs. Bot.*; see *velutina*, n 14. The name however of *holosericea* is not so applicable to the plant before us, as that given by Swartz, by which it is most generally known, and which for that reason we have retained, as the best means of avoiding mistake.

56—57. M. *cyanoides*. (Fragarius ruber; Rumph. Amb. v. 4. 135. t. 71. Katou-Kadali; Rheede Malab. v. 4 91. t. 43.)—Leaves ovate, acute, five-ribbed, entire; roughish on both sides with close-pressed bristles. Clusters terminal, forked. Calyx clothed with clustered bristles. Bracteas ovate, fringed.—Sent from Amboyna by the late Mr. Christopher Smith. We can refer it to none in Willdenow or Lamarck, but we quote without hesitation the above synonyms, which have been, surely erroneously, referred to the true *M. aspera*; see n. 10. The present is rather a small and weak *shrub*, with slender, grey, slightly bristly *branches*. *Leaves* bright green on both sides, paler beneath, ovate, rather pointed, three inches long, and above one broad, with five distinct ribs, of which the lateral ones are nearly as considerable as the rest. The upper surface is besprinkled with yellow close-pressed *bristles*; the under is chiefly bristly at the ribs and veins. *Footstalks* bristly, purplish, half an inch long. *Panicles* terminal, forked or corymbose, a little bristly, with a pair of ovate, concave, smooth though fringed *bracteas*, at each division. *Calyx* densely covered with clustered, sometimes palmate, whitish bristles, which are, as far as we have seen, peculiar to this species, and give the part in question a great resemblance to *Centaurea Cyanus*. The *petals* are said by Rumphius to be white; in the Hortus Malabaricus they seem implied to be purple. The *fruit* is compared by the former author to a strawberry, being redder on one side than the other. It is agreeably acid, with some astringency, and is given to children in Amboyna, to prevent what some learned corruptor of English may hereafter call lectimiction.

Section 6. *Stamens eight*; *leaves with three separate ribs*.

59. M. *microphylla*. Swartz. Ind. Occ. 813; is erroneously placed here. It has ovate, obtuse, hairy *leaves*, about an inch long, most evidently triple-ribbed. The *flowers* are small, with a very hispid *calyx*, and stand in the forks of the branches, one usually nearly sessile, with two or three others on capillary, hairy, simple stalks. The *fruit* looks like that of a *Croton*, but has four furrows; nor are the leaves dissimilar to some of that genus, yet we cannot refer our plant to *M. crotonifolia*, n. 35. of Lamarck. The present species is but ill compared by Swartz to his *hirsuta*, which we have from himself, and which is more related to *hirta*; see n. 32. It must always be remembered that these sections of the genus, which we have adopted from Willdenow, are entirely artificial, as well as somewhat inconstant.

61. M. *capillaris*. Swartz. Ind. Occ. 808.—Leaves lanceolate, pointed, three-ribbed, smooth, nearly entire. Stalks axillary, capillary, three-flowered. Native of hills in the south parts of Jamaica. A very fair example of this section. It is remarkable for its extremely minute, whitish, short-lived *flowers*, which stand, three together, on roughish, capillary, axillary stalks. The *calyx* has four minute upright teeth. The *berry* also is perhaps the smallest in the whole genus. The young *leaves* are somewhat downy beneath, but the full-grown ones are smooth, three inches long, narrow, taper-pointed, pale at the back, with three ribs, and strong, simple, transverse veins. We have a specimen from its discoverer.

64. M. *glandulosa*. Swartz. Ind. Occ. 799.—Leaves ovate, entire, with three ribs besides the marginal ones, hispid on both sides, with axillary tufts of bristles at the veins beneath. Panicles terminal, three-forked, very rough. Gathered by Masson and Swartz on the loftiest hills of Jamaica. This is akin to some of the roughest leaved species before described, but distinguished by pale tufts of bristles at the separation of each vein from the midrib beneath. The *leaves* are about three inches long, and more than one broad; the bristles of their upper side most rigid, yellow and hooked. *Panicle* spreading, many-flowered, excessively hispid. *Petals* four, with longish claws. *Stamens* eight. *Anthers* bordered at each side with a yellow membrane. *Style* long and prominent. We cannot but remark that this is properly a five-ribbed species, and ought to stand in a section hereafter mentioned.

67. M. *octandra*. Linn. Sp. Pl. 560. (M. foliis lanceolatis trinerviis glabris, margine hispidis; Linn. Zeyl. 76. n. 173, excluding the synonyms. M. repens; see n. 21.)—Leaves ovate, entire, three-ribbed, smooth, with a simple marginal row of close-pressed bristles. Flowers terminal, mostly solitary. Calyx bristly.—Native of Ceylon and China. The *stem* is rather woody, but prostrate, branched and creeping. *Leaves* about an inch long, of a broad ovate obtuse figure, three-ribbed, besides an occasional pair of obsolete marginal ribs; dark green above; very pale and yellowish beneath; smooth and naked on both sides, except a few hairs on the ribs beneath, and a very remarkable row of marginal close-pressed oblique bristles, on the upper side, resembling stitches of thread; these are sometimes partially wanting. *Flowers* terminal, mostly solitary, large, purple, very handsome. *Calyx* clothed with simple incurved bristles. *Petals* fringed, barbed at the summit with a bristly tuft.

Lamarck was led by the synonym of Burmann, erroneously quoted by Linnæus, to describe and figure this real *M. octandra* of the latter as a new species, by the name of *repens*. This name however we should wish to retain, as the *flowers* in our specimens are most frequently five-cleft and decandrous. We know not why the *leaves* have ever been described as in any degree lanceolate, they being truly ovate. Half the *stamens* appear to be always abortive.

69. M. *tetrandra*. Swartz. Ind. Occ. 795.—Leaves three-ribbed, oblong, pointed, entire, smooth, with a notch at the base. Cluster erect, terminal. Stamens four.—Native of the Blue mountains in the south of Jamaica, but very rare. Flowering in May. This is a middling-sized *tree*, whose young branches are square, and nearly smooth. *Leaves* three or four inches in length, and one in breadth, on long stalks, smooth, entire, pointed, rounded at the base, with a notch at the footstalk. They have one strong central rib, with a slight marginal pair only. The *flowers* we have not seen. Dr. Swartz describes them as small and white, in a terminal compound cluster, which is rough with rusty mealiness. They are four-cleft, with but four *stamens*. *Berry* minute, roundish.

71. M. *angustifolia*. Swartz. Ind. Occ. 796.—Leaves three-ribbed, linear-lanceolate, entire; hoary beneath. Branches wand-like. Clusters terminal, repeatedly three-forked, mealy and rusty.—Native of Jamaica and other West Indian islands. A slender *shrub*, distinguished by its elegant narrow *leaves*; of a bright yellowish-green, and smooth, above; hoary and slightly rusty, with beautifully regular transverse veins beneath. *Clusters* terminal, stalked, with

with many forked, ſpreading, cymoſe branches. *Calyx* mealy. *Petals* four, pale yellow. *Stamens* eight.

Section 7. *Stamens eight; leaves with three combined ribs.*

78. M. *ſcabroſa*. Linn. Sp. Pl. 558. Swartz. Obſ. 174. (M. n. 5; Browne Jam. 219. t. 24. f. 3.)—Leaves ovate, crenate, triple-ribbed, rough and hairy. Branches denſely ſhaggy. Flowers axillary, aggregate, octandrous.—Native of the cooler mountains of Jamaica. A *ſhrub* about a man's height, whoſe branches are denſely covered with ſhort ſhaggy hairs, like the ſtalks and ribs of the *leaves*, which laſt are broad-ovate, three inches long, very harſh and hiſpid on both ſides, furniſhed with three ribs combined at their baſe, and two diſtinct ones nearer the margin, which is irregularly crenate. Swartz deſcribes the *flowers* as very minute, pale red, ſeſſile and axillary. Of theſe Browne's ſpecimen in the Linnæan herbarium retains two or three, which however ſtand on ſtalks, about as long as the *calyx*. The ſegments of the latter are awl-ſhaped.

Section 8. *Stamens eight; leaves with five ribs.*

80. M. *umbroſa*. Swartz. Ind. Occ. 817.—Leaves roundiſh-ovate, pointed, finely toothed, hairy on both ſides. Cluſters axillary, compound, briſtly, ſpreading.—Found in ſeveral of the Weſt Indian iſlands. This ſpecies has very hiſpid *branches* and *ſtalks*, and is remarkable for its large, almoſt round, taper-pointed *leaves*, broader than the hand, which have five ribs, beſides the marginal ones, all running from the baſe to the extremity. The *cluſters* are axillary, and in pairs, ſcarcely longer than the footſtalks, twice compound, ſpreading widely. *Bracteas* ſpatulate, recurved, briſtly. *Flowers* white, very ſmall.

85. M. *coccinea*. Vahl. Eclog. v. 1. 48.—Leaves elliptic-ovate, pointed, five-ribbed, entire, ſmooth. Branches hiſpid at intervals.—Native of the iſland of Montſerrat. *Stem* arboreous. *Branches* bluntly quadrangular, hollow, knotty, clothed here and there with irregular interrupted tufts of horizontal pale hairs, like radicles. *Leaves* ſeveral inches in length and breadth, ſmooth, entire, with five ribs beſides the two marginal ones, the three in the centre ſlightly combined at their baſe. The *flowers* are ſaid to be ſcarlet, or occaſionally white, forming a terminal *thyrſus*, which we have ſeen but in an imperfect condition. S.

Melastoma, in *Gardening*, contains plants of the evergreen tree and ſhrubby exotic kinds, of which the ſpecies cultivated are, the American gooſeberry of Surinam (M. groſſularioides); and the ſattiny-leaved melaſtoma (M. holoſericea).

But there are other ſpecies which may be cultivated.

Method of Culture.—Theſe tender plants are beſt obtained by having the entire fruits put up in their native places in dry ſand as ſoon as ripened, and immediately forwarded, which as ſoon as they arrive ſhould be taken out, and the ſeeds ſown in pots of light earth, plunging them in a moderate hot-bed of tanners' bark: when the plants are up, and fit to remove, they ſhould be planted each in a ſmall pot of light earth, replunging them in the tan-bed of the ſtove.

Afterwards they require the management of other woody ſtove-plants.

And they may alſo be increaſed by laying the young branches in the ſpring, or by planting cuttings of the young ſhoots in the ſummer ſeaſon in pots, and plunging them in a hot-bed. They ſhould afterwards have the ſame culture as the other kinds.

MELASTOMÆ, in *Botany*, a very beautiful but not extenſive natural order in Juſſieu's ſyſtem, of which the genus from whence the name is derived makes the principal part. (See Melastoma.) This order is the 90th of Juſſieu, the eighth of his 14th claſs. The characters of that claſs are given under the article Ficoideæ. It has two cotyledons, many petals, and ſtamens inſerted into ſome part of the calyx.

The *Melaſtomæ* are thus diſtinguiſhed.

Calyx of one leaf, tubular, either ſuperior or inferior, ſimple or ſurrounded with ſcales. *Petals* ſeveral, of a definite number, inſerted into the top of the calyx, equal in number to its ſegments and alternate with them. *Stamens* inſerted into the ſame place, of a definite number, which is double that of the petals; the top of the filaments, beneath the anthers, moſtly furniſhed with two briſtles, or two auricles; anthers long, beaked at the ſummit, attached by their baſe to the top of the filaments, and, at firſt, drooping, in conſequence of the filaments being bent inwards; but as the latter afterwards become ſtraight, the anthers riſe upwards. *Germen* ſometimes ſuperior, enfolded by the calyx, ſometimes inferior; ſtyle ſolitary; ſtigma ſimple. *Fruit* either pulpy or capſular, inveſted, when ſuperior, with the calyx, which is contracted above; when inferior, attached to the ſame part, and ſwelling beneath it, of many cells, with numerous ſeeds in each cell. *Corculum* ſuſpected by Juſſieu to be unaccompanied with albumen. *Stem* rather arboreous, or ſhrubby, or rarely herbaceous. *Leaves* oppoſite, ſimple, with three or more longitudinal ribs. *Flowers* oppoſite, either axillary or terminal, their ſtalks either ſingle or many-flowered.

The firſt ſection is ſaid to have an inferior germen, and conſiſts of *Blakea* of Browne and Linnæus, to which it is doubtful whether the *Blakea* of Aublet be properly united as one genus; *Melaſtoma*, ſee that article; and *Triſtemma*, a genus of Juſſieu's, brought by Commerſon from the Mauritius.

Section the ſecond is characterized by a ſuperior germen, and conſiſts of *Topobea* of Aublet, with *Tibouchina*, *Mayeta* or *Maieta*, and *Tococa* of the ſame author, which two laſt are now referred to *Melaſtoma*, there being really no generic diſtinction. To theſe are added *Oſbeckia* and *Rhexia* of Linnæus, whoſe fruits are capſular.

The plants of this order are, on the one hand, akin to the *Myrti*, and on the other to the *Salicariæ*, but diſtinguiſhed from both by their very conſpicuous large and long-beaked anthers, with appendages at their baſe. By the definite number of their ſtamens they are moreover diſtinguiſhed from the *Myrti*, to which we may add the peculiarly ribbed leaves, and rigid depreſſed pubeſcence, of many ſpecies, and the want of an aromatic quality. To the *Salicariæ* they are more ſimilar in habit.

Number of parts is one of the moſt variable circumſtances belonging to this order, the ſtamens differing in different ſpecies, and even varying ſometimes in the ſame, from eight to ten, or from ten to twelve; and conſequently the petals and calyx-teeth from four to five or ſix; of which the genus *Melaſtoma* affords inſtances.

MELAVERD, in *Geography*, a town of Perſia, in the province of Irak; 45 miles N.E. of Iſpahan.

MELAUI, or Mellavoué, a ſmall and tolerably handſome town of Egypt, ſituated half a league from the W. bank of the Nile, and the reſidence of a "kiaſchef." The plain ſurrounding it is very fertile, particularly in corn, a great quantity of which is exported by way of Cairo, Suez, and the Red ſea to Mecca, and other parts of Arabia. The Chriſtians have no church, but repair to the convent on the other ſide; 120 miles S. of Cairo. N. lat. 28° 2′.

MELAZZO, or Milazzo, anciently *Mylæ*, a ſea-port town of Sicily, in the valley of Demona, ſituated in a bay on the N. coaſt of the iſland. It conſiſts of two parts, one of which ſtands on a promontory of the ſame name, and

and is fortified: the other, on a bay, with a good harbour, the entrance of which is defended by a castle; 18 miles W. of Messina. N. lat. 38° 16'. E. long. 15° 23'.

MELBON, one of the cluster of the "Seven Islands," in the English channel, near the coast of France. N. lat. 48° 54'. W. long. 3° 22'.

MELBY, a town of Norway, in the province of Aggerhuus, on the Glomme; 55 miles N.E. of Christiania.

MELCAPOUR, a town of Hindoostan, in the Candeish; 20 miles S. of Burhampour.

MELCHITES, or MELECHITES, in *Ecclesiastical History*, were those Christians in Syria, Egypt, and the Levant, who in the seventh century, though not Greeks, followed the doctrines and ceremonies of the Greek church. They were called *melechites*, i. e. *royalists*, from the Hebrew *melech*, *king*, by their adversaries, by way of reproach, on account of their implicit submission to the edict of the emperor Marcian, in favour of the council of Chalcedon. For the same reason the emperor Justinian had the epithet Chalcedonensis given him.

MELCHIZEDECH, in *Biography*, king of Salem, and priest of the most high God, is mentioned in the scriptures, but without any reference to his genealogy, or to his birth or death: and in this sense, it has been asserted, he was a figure of Jesus Christ, as is affirmed in the epistle to the Hebrews, "Who is a priest for ever, according to the order of Melchizedech," and not according to the order of Aaron, whose origin, life, and death are known. When Abraham returned from pursuing the confederate kings, who had defeated the kings of Sodom and Gomorrah, and had taken away Lot with them, Melchizedech came to meet Abraham, and presented to him bread and wine with his benediction. (Gen. xiv. 17, &c.) Abraham, being desirous to acknowledge in him the quality of priest of the Lord, offered him the tythes of all that he had taken from the enemy. After this time there is no mention made of Melchizedech, till the 110th psalm, where, in allusion to the Messiah, it is said, "Thou art a priest for ever after the order of Melchizedech." It having been asserted, that he was without father or mother, some of the early Christians assumed that he was a celestial being, superior to angels. These obtained the name of *Melchizedechians;* which see.

MELCHIZEDECHIANS, or MELCHISEDEKIANS, ancient sectaries, so called, because they raised Melchizedech above all creatures, and even above Jesus Christ.

The author of this sect was one Theodotus; whence the Melchizedechians become more commonly known by the name of Theodotians; all the difference between those and the strict Theodotians consisting in that particular article relating to Melchizedech; who, according to them, was the great and supreme virtue.

This sect was revived in Egypt towards the close of the third century by Hierax. (See HIERACITES.) Those also in later times, who have maintained that Melchizedech was the son of God in a human form, may be distinguished by this appellation. See Cunæus de Rep. Hæbræorum.

MELCK, or MÖLK, in *Geography*, a town of Austria, near the Danube. In its vicinity is a famous cloister of Benedictines, seated on a rock; its library is said to consist of some curious and valuable MSS.; 11 miles W. of St. Polten.

MELCOMBE-REGIS, a borough and market-town in the hundred of Uggescombe, Dorchester division of the county of Dorset, England, is situated eight miles from Dorchester, 127 miles from London, at the mouth of the river Wey, which separates it from Weymouth. The population of Melcombe in the year 1801, according to the return made to parliament, was 2350, occupying 471 houses. This borough has sent two representatives to parliament ever since the reign of Edward II. Melcombe and Weymouth are so frequently joined in ancient grants, that there is some difficulty in separating them; though each had distinct privileges; of which Melcombe, being the favoured borough, and part of the demesne of the crown a considerable time before Weymouth, had the greatest share, and is principally noticed in succeeding charters to the exclusion of its neighbour. Hence arose disputes between the rival boroughs respecting their privileges: and the contention had arrived to so great a height in the reign of Elizabeth, that the expediency of a union became apparent; and they were accordingly incorporated by an act passed in the 13th year of that queen (afterwards confirmed by James I.) and directed to be called "The united town and borough of Weymouth and Melcombe-Regis." The civil government, with other local circumstances relative to Melcombe, will be found under WEYMOUTH. Sir James Thornhill, the celebrated painter of the cupola of St. Paul's cathedral and the halls of Greenwich hospital and Blenheim, was born at Melcombe in the year 1675, and died at his seat at Thornhill, near this town in 1734. (See THORNHILL.) Beauties of England and Wales, vol. iv. Hutchin's History of Dorchester, 2 vols. folio.

MELCONDA, a town of Hindoostan, in Dowlatabad; 23 miles W. of Beder.

MELDAL, a town of Norway, in the province of Drontheim; 30 miles S.S.W. of Drontheim.

MELDFEE, in our *Old Writers*, a recompence due and given to him that made the discovery of any breach of penal laws, committed by another person, called the promoter's or informer's fee.

The word is Saxon, from *meldfeoh*.

MELDOLA, in *Geography*, a town of Italy, in the department of the Rubicon; seven miles S. of Forli.

MELDORP, a sea-port of Holstein, at the mouth of the river Myle; 50 miles N.W. of Hamburgh. N. lat. 54° 10'. E. long. 9° 4'.

MELDRUM, a town of Scotland, in the county of Aberdeen, being a burgh of barony, and holding a weekly market; 16 miles N.N.W. of Aberdeen.

MELEAGER, in *Biography*, a Greek poet, son of Eucrates, was a native of Gadara, in Syria, or of Atthis, a village in its territory, and is supposed to have flourished about a century before the Christian era. He spent his youth chiefly at Gadara, where he formed himself upon the style and manner of Menippus, an elder poet of that place. He afterwards resided at Tyre, and finally passed over to Cos by way of refuge from the wars which ravaged Syria, and died there at an advanced age. He was the first who made a collection of the short poems called by the Greeks epigrams. Of these he formed two sets, under the title of "Anthologia," the *first* of which was a lamentable proof of the licentiousness of the age and country; the *second*, consisting of miscellaneous pieces, has formed the basis of the later anthologias of Agathias and Planudes. Many of the poems are the work of Meleager, and possess much elegance: an edition of the poems was given by Brunck in 1709. Gen. Biog.

MELEAGRIS, in *Natural History*, a genus of birds of the order Gallinæ. Bill conic, incurvate; head covered with spongy caruncles; chin with a longitudinal membranaceous caruncle; tail broad, expansile; legs spurred. According to Buffon, there is but one known species, which he says is a large unwieldy bird, the anterior part of the head

head is ſtrangely covered and ornamented with a pendulous, ſoft, and fleſhy ſubſtance, as alſo are the ſides of the head and throat; the eyes are ſmall, but bright and piercing; the bill convex, ſhort and ſtrong; a long tuſt of coarſe black hairs on the breaſt, the wings moderately long, but not at all formed for ſupporting ſo large a bulk in long flights; the legs moderately long, and very robuſt. In Gmelin's edition of Linnæus, two ſpecies are mentioned, namely, the Gallipavo and Satyra, of which the following are the characteriſtics.

Species.

Gallipavo. Front and chin carunculate; breaſt of the male tufted. It inhabits America; is above three and a half feet long, is domeſticated every where, and varies much in its colours; in a wild ſtate, it lives in woods and feeds on nuts, acorns, and inſects; rooſts on the higheſt trees, is very iraſcible and impatient of any thing red; the cock ſtruts with an inflated breaſt, expanded tail, red face and relaxed frontal caruncle, and makes a ſingular inward noiſe, which, when it is uttered, ſhakes the whole body; eggs numerous, white, with reddiſh or yellow ſpots; it has eighteen tail-feathers. The female has no ſpur.

Satyra. Head with two horns; body red with eye-like ſpots. This is called the horned turkey. It inhabits India, and is leſs than the laſt ſpecies. The bill brown; noſtrils, front, and area of the eyes covered with black hair-like feathers; crown red; horn callous, blue, bent back; caruncle of the chin dilatable, blue, varied with rufous; legs whitiſh, ſpurred; it has 20 tail-feathers. The female has its head covered with feathers, without horns or gular caruncle; feathers of the head and upper part of the neck black-blue, long, decumbent; reſt of the body as in the male, red, with eye-like ſpots; ſpurs more obtuſe.

Meleagris, the Guinea-hen or Pintado, a ſpecies of *Numida*; which ſee.

Meleagris, in *Zoology*, a ſpecies of *Anguis*.

MELEDA, in *Geography*, an iſland in the Adriatic, ſeparated from the peninſula of Sabioncello by a narrow channel, belonging to the republic of Raguſa. It is about 30 miles long, and of an unequal breadth, and is interſected by many bays and inlets, which afford good harbours for fiſhermen. It produces vines, orange and lemon trees, but not ſufficient corn for the inhabitants, who amount to about 2000, occupying ſix or ſeven villages. N. lat. 43° 5'. E. long. 17° 44'.

MELELA, a town of Africa, in Barca; 76 miles S.W. of Tolometa.

MELEMBA, a town of Cacongo. S. lat. 5° 30'. E. long. 11° 55'.

MELENES, a ſmall iſland in the Engliſh channel, near the coaſt of France. N. lat. 48° 48'. W. long. 3° 31'.

MELENKI, a town of Ruſſia, in the government of Vladimir, on the Oka; 44 miles S.E. of Vladimir. N. lat. 60° 24'. E. long. 41° 24'.

MELES, Badger, in *Zoology*, a ſpecies of *Urſus*; which ſee.

MELETIANS, in *Eccleſiaſtical Hiſtory*, the name of a conſiderable party, who adhered to the cauſe of Meletius, biſhop of Lycopolis, in Upper Egypt, after he was depoſed about the year 306, by Peter, biſhop of Alexandria, under the charge of his having ſacrificed to the gods, and having been guilty of other heinous crimes; though Epiphanius makes his only failing to have been an exceſſive ſeverity againſt the lapſed. This diſpute, which was at firſt a perſonal difference between Meletius and Peter, became a religious controverſy; and the Meletian party ſubſiſted in the fifth century; but was condemned by the firſt council of Nice.

MELETIN, in *Geography*, a river of European Turkey, which runs into the Pruth, 12 miles N. of Jaſſi, in the province of Moldavia.

MELETZKOI, a town of Ruſſia, in the province of Tobolſk; 44 miles N. of Archinſk.

MELFI, a town of Naples, in Baſilicata, the ſee of a biſhop, containing ſeven churches and eight convents; five miles N.W. of Venoſa. N. lat. 41° 1'. E. long. 15° 39'.

MELFORD, Long, an extenſive village, ſituated near the river Stour, in the hundred of Babergh, and county of Suffolk, England. It is about one mile in length, whence the characteriſtic appellation *long*, and contains, according to the parliamentary returns of 1801, 450 houſes, and 2204 inhabitants, *viz.* 1034 males and 1173 females. Of theſe 1837 were returned as employed in different departments of trade. Few villages in England can boaſt of a more agreeable ſituation than this, the immediate vicinity being diſtinguiſhed by much beautiful and pictureſque ſcenery. The church, which ſtands on an elevated ſpot at the north end of the village, is a curious piece of architecture in the pointed ſtyle of the fifteenth century. Its length is 180 feet, excluſive of the ſchool-houſe at the weſtern extremity. The chancel, or eaſt end, is diſtinguiſhed for its maſonry, conſiſting of flint work, and ſquared ſtones; and beneath the parapet is an inſcription in old letters. In the north aiſle is an altar tomb for William Clopton, eſq., whoſe ſtatue, in armour, reſts on the top; he died in 1446. His ſon, John Clopton, who was ſheriff of the counties of Norfolk and Suffolk in the time of Henry VI., was interred under an altar tomb in the chancel. Near the communion table is a large and ſtately marble monument to the memory of ſir William Cordell, who was ſpeaker of the houſe of commons in the reign of queen Mary. This gentleman founded an hoſpital here, which is ſtill ſtanding, almoſt cloſe to the church. It is a reſpectable brick building, and is ſufficiently endowed for the ſupport of a warden, twelve poor men, and two women, who are required to be old and decayed houſekeepers of Melford. Several Roman urns have been dug up in this pariſh within theſe few years. At a ſhort diſtance eaſt of the church is Melford Hall, the ſeat of ſir H. Parker, bart. The houſe, a large brick building, appears to be of the age of queen Elizabeth. At the diſſolution of religious houſes, this eſtate was granted to ſir William Cordell. About half a mile north of the church is Kentwell Hall, formerly the ſeat of the Cloptons, but now the ſeat of Richard Moore, eſq. The houſe is large, and was formerly ſurrounded by a moat, three ſides of which are ſtill remaining; the fourth, or eaſt ſide, has been filled up. Beauties of England and Wales, vol. xiv. by F. Shoberl. Kirby's Suffolk Traveller.

MELGAR, a town of Spain, in Old Caſtile; 23 miles W.N.W. of Burgos.

MELGASSO, a town of Portugal, in the province of Entre Duero e Minho, ſituated on the Minho, and defended by a caſtle; 30 miles N. of Braga. N. lat. 42° 5'. W. long. 8°.

MELHANIA, in *Botany*, Forſk. Ægypt.-Arab. 64. Juſſ. 277; a genus of Forſkall's, named by him from Melhân the Arabic appellation of the hill upon which he gathered it, and which is rich in curious plants. He deſcribes this as a branched ſpreading *ſhrub*, two cubits high, with ſoft, ovato-lanceolate, ſerrated *leaves*, and yellow, axillary, ſtalked *flowers*. The *calyx* is double; the outer of three, inner of five, leaves. *Stamens* five, inſerted into a nectari-

ferous

ferous crown, with five intermediate linear bodies, exceeding them in length. *Style* one, with five stigmas. *Capsule* globose, of five cells and five valves. *Seeds* four in each cell, angular, dotted.

The only species in *M. velutina*, described above. Jussieu suspects it to be of the same genus as *Dombeya* and *Assonia* of Cavanilles, both united under the latter name by Schreber. Our plant is *Dombeya velutina*, Willd. Sp. Pl. v. 3. 726. (Pentapetes velutina; Vahl. Symb. v. 1. 49.) We have already objected to this *Dombeya* in describing the true one. See Dombeya.

MELHUA, or Melluah, in *Geography*, a town of Syria, in the desert; 20 miles S.E. of Aleppo.

MELIA, in *Botany*, a name adopted by Linnæus for this tree, apparently because its leaves resemble those of the *Ash*, which is doubtless the true Μελια of the ancient Greeks. Linn. Gen. 211. Schreb. 286. Willd. Sp. Pl. v. 2. 558. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 39. Juss. 265. Lamarck Illustr. t. 352. Cavan. Diss. 363. (Azedarach; Tournef. t. 387.)—Class and order, *Decandria Monogynia*. Nat. Ord. *Trihilatæ*, Linn. *Meliæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, very small, five-toothed, erect, obtuse. *Cor.* Petals five, linear-lanceolate, spreading, long. Nectary cylindrical, of one leaf, the length of the corolla, with a ten-toothed mouth. *Stam.* Filaments ten, very small, situated within the apex of the nectary; anthers oblong, not protruding beyond it. *Pist.* Germen conical; style cylindrical, the length of the nectary; stigma capitate, with five, conniving valves. *Peric.* Drupa globose, soft. *Seed* a roundish, five-furrowed, five-celled nut.

Ess. Ch. Calyx five-toothed. Petals five. Nectary cylindrical, toothed at its mouth, bearing the anthers. Drupa a nut of five cells.

1. M. *Azedarach.* Common Bead-tree, or Pride of China.—Linn. Sp. Pl. 550. Sims in Bot. Mag. t. 1066. Sm. Ins. of Georgia, v. 2. t. 90.—Leaves bipinnate; leaflets smooth, about five. Native of Syria, and common in Spain. Cultivated, in 1656, by Mr. John Tradescant jun. It flowers from June to August. This beautiful *tree* grows to a large size in warm countries, and is much branched. *Leaflets* ovate, notched, pointed, green above, paler beneath. *Flowers* lateral, in long, loose panicles. Petals white, streaked with pink. *Fruit* oblong, the size of a cherry, of a pale yellow when ripe.—The pulp which surrounds the nut is poisonous, and "in the southern parts of Europe, the *nuts* are threaded for beads to assist the devotion of good Catholics, for which purpose they are peculiarly suited, having a natural perforation through the centre; hence the tree has been called *arbor sancta*, and by the Spaniards *arbol parayso.*" *Sims.*

2. M. *sempervirens.* Evergreen Bead-tree. Swartz. Prod. 67. Ind. Occ. v. 2. 737. (M. Azedarach β; Linn. Sp. Pl. 550. Azadirachta indica, &c.; Com. Hort. Amst. v. 1. 147. t. 76.)—Leaves bipinnate; leaflets somewhat rugose, generally about seven.—A native of the East and West Indies, in which latter country it is called Indian lilac. In separating this from the last species, we have the authority of Swartz, who says that the whole plant is considerably smaller, that the *leaflets* are of a brighter green, seldom more than seven, somewhat wrinkled, more deeply and unequally serrated and pointed. In addition to these marks of distinction its *foliage* is not deciduous. The author of the Botanical Magazine has not thought proper to disunite them, but we do not think his reasons conclusive.

3. M. *Azadirachta.* Ash-leaved Indian Bead-tree. Linn. Sp. Pl. 550. Cavan. Diss. t. 208. (Aria Bepou; Rheed. Hort. Mal. v. 4. t. 52.)—Leaves pinnate.—A native of the East Indies, flowering in June and July.—The stem of this tree is large and thick. The *wood* of a pale yellow; the *bark* of a dark purple, and very bitter. *Leaves* composed of five or six pairs of oblong, pointed leaflets, terminated by an odd one. These are opposite or alternate, on long footstalks, smelling disagreeably. *Flowers* small, white, lateral, in long, branching panicles. *Fruit* oval, the size of small olives, green, turning yellow, and purple when ripe; its pulp abounds with an acrid and bitter oil, some of which was sent by Dr. Roxburgh to the President of the Linnæan society in 1792, with the character of an excellent vermifuge.

4. M. *dubia.* Cavan. Diss. 364.—Leaves bipinnate; leaflets broadly lanceolate, acute, serrated, the terminal one larger. Sent by M. Sonnerat to Lamarck from the East Indies.—All that we know of this species is from Cavanilles, who says that he saw a single specimen of it in Lamarck's herbarium without any name, but that he easily discovered it belonged either to *Trichilia* or *Melia*, and that he referred it to the latter genus from its fruit. The *flowers* resemble those of *M. Azadirachta*.

5. M. *composita.* Willd. n. 5.—Leaves pinnate; lower leaflets ternate, on stalks. Calyx and corolla downy.—A native also of the East Indies.—At the end of Willdenow's description of this species, he says, that *M. dubia* of Cavanilles seems very nearly allied to it.—It occurs nowhere but in the above quoted author, upon whose sole authority we adopt it. The pubescence of the *calyx*, and outer side of the *petals*, seems to be the great mark of distinction. The *fruit* is unknown.

Melia, in *Gardening*, comprises plants of the deciduous and evergreen exotic tree kinds, of which the species cultivated are; the common bead-tree (M. azedarach); the evergreen bead-tree (M. sempervirens); and the Indian evergreen bead-tree (M. azadirachta.)

Method of Culture.—These different plants are all capable of being increased by seeds, which in the first sort are obtained from abroad, and should be sown in pots of light rich earth in the spring, plunging them in a hot-bed of tanners' bark or dung, under frame and glasses, giving frequent waterings, and fresh air, when the plants are come up, being fully exposed in a moderate shade, during the summer, and placed under a frame in the autumn, &c. to have the free air all winter in open weather, and be sheltered from frost.

But in the following March they should be planted in separate small pots, plunged in a bark-bed, &c. Though this last is not absolutely necessary, yet when practised, it greatly facilitates their rooting and early growth.

After they have been managed in this way for three or four years, and shifted occasionally into larger pots; some of the strongest and most woody plants may be planted out in the full ground under a warm wall, or in a dry sheltered part of the shrubbery. The proper season for this work is the first fortnight in April. And some plants should likewise be placed in pots, to have the management of green-house exotic plants, lest those in the open ground should be destroyed by the frost during the winter season.

The seeds in the second and third sorts, should be sown in pots, and plunged in the bark-bed, and managed nearly as the first sort; but, as being much more tender, must be always kept in pots, and plunged in the tan-bed in the stove during their early growth; afterwards, when they have acquired considerable size and strength, they may be placed in the open air for a month or two in the heat of summer, but the rest of the year be kept in the hot-house; managing them as other woody exotic stove plants.

It

It may be noticed that the laſt ſort is not common in the gardens.

In regard to the firſt ſort, it is proper for ſhrubberies and other parts in warm ſituations, as well as for the green-houſe, and the others for ſtove collections, in mixture with the more tender plants.

MELIA *Terra*, in *Natural Hiſtory*, a name given by ſome authors to the *melinum*, or white earth of the iſland of Melos, uſed among the ancients in painting; but in the works of Dioſcorides and Galen ſignifying a ſubſtance of a very different kind; the melinum of the painters having been a marle, and the melia terra of the phyſicians a tripela.

The terra melia of Dioſcorides, and the ancient phyſicians, is a dry looſe, and harſh earth, found in maſſes of different ſize, and lodged among the looſer ſtrata of other matter, never making a ſtratum of itſelf. It is very firm and hard, of a pale greyiſh-white or light aſh-colour, very heavy, of a looſe, open, and ſpungy texture, and of a rough uneven, and duſty ſurface. It adheres ſlightly to the tongue, and does not ſtain the hand, and leaves a duſt after the handling, which is ſo harſh as to make a grating noiſe, when the fingers are afterwards rubbed together. It makes no effervescence with acids. It is found in all the iſlands of the Archipelago, and was uſed by the ancients for the ſame purpoſes with the pumices.

MELIÆ, in *Botany*, one of Juſſieu's Natural Orders of plants, the 71ſt in his ſyſtem, or eleventh of his thirteenth claſs, derives its name from the moſt familiar genus among them; ſee MELIA. For the characters of the thirteenth claſs ſee GERANIA and GUTTIFERÆ. The following are the characters of *Meliæ*.

Calyx of one leaf, divided either down to the baſe, or only at the apex. *Petals* four or five, with broad claws, for the moſt part cohering at the bottom. *Stamens* of a definite number, either as many as the petals, or more generally double that number, their filaments united into a tube or cup, toothed at its ſummit, the teeth either bearing the anthers, or overtopping them when attached to their lower part, at the inſide. *Germen* ſingle; with a ſingle ſtyle; the ſtigma ſimple, or, more rarely, divided. *Fruit* either pulpy, or more generally capſular, of many cells, each containing one or two ſeeds, the valves equal in number to the cells, with partitions from the middle of each valve. The *ſtem* is ſhrubby or arboreſcent, with alternate branches. *Leaves* alternate, without ſtipulas, ſimple or compound.

The firſt ſection, with ſimple leaves, conſiſts of *Canella* of Browne, Swartz and Schreber (*Winterania* of Linnæus and Juſſieu), *Symphonia*, *Tinus*, *Geruma* of Forſkall (ſee that article), *Aitonia*, *Quiviſia* of Commerſon, and *Turræa*.

The ſecond, with compound leaves, compriſes *Ozophyllum* of Schreber (*Ticorea* of Aublet), *Sandoricum* of Rumphius, Schreber and Juſſieu, *Porteſia* of Juſſieu, *Trichilia*, *Elcaja* of Forſkall, *Guarea*, *Ekebergia*, *Melia* and *Leea*, which laſt is alſo *Aquilicia* of Linnæus. See LEEA.

A third ſection is ſubjoined by Juſſieu, of genera akin to *Meliæ*. Theſe are *Swietenia* and *Cedrela*. They differ widely from the proper genera of the order in their fruit, which is in both of them a woody capſule of five valves, ſplitting from the baſe, and containing numerous, imbricated, compreſſed, winged ſeeds.

The order in queſtion is by no means one of the moſt natural in its learned author's ſyſtem; at leaſt with reſpect to the affinities of ſome of the genera which he has referred to it.

MELIANTHUS, from μελι, *honey*, and ανθος, *a flower*, ſo named from the abundance of honey which flows from *M. major* in particular, for, as Linnæus remarks, if that ſpecies be ſhaken whilſt in flower, it diſtils a ſhower of nectar. Juſſieu tells us that *Melianthus* is allied to *Tropæolum* in the hood of the calyx, and ſituation of the petals and ſtamens; but that it is more like *Dictamnus* in habit, fruit, and albumen of the ſeed. He well remarks however that it is very diſtinct from either of thoſe genera, on which ſubject there cannot be the leaſt queſtion. We are told that the Linnæan botaniſts at Paris uſed ſarcaſtically to remark that *Melianthus* was not admitted into the public garden there, becauſe no plauſible place could be found for it in the ſyſtem of the Juſſieus.—Linn. Gen. 328. Schreb. 430. Willd. Sp. Pl. v. 3. 402. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 2. 367. Tournef. t. 245. Juſſ. 297. Lamarck Illuſtr. t. 552.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Corydales*, Linn. *Rutaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, large, coloured, cloven into five, unequal ſegments, the two upper ones oblong, erect, the loweſt one very ſhort, bag-ſhaped, ſwelling downwards, the intermediate two oppoſite, interior, lanceolate. *Cor.* Petals four, linear-lanceolate, reflexed at their tips, ſpreading in a parallel manner, turned outwards, forming a lower lip (as the calyx does an upper one) connected in the centre by their ſides. Nectary of one leaf, ſituated within the loweſt ſegment of the calyx, and adhering with it to the receptacle, very ſhort, compreſſed at the ſides, cut at the margin, and turned downwards at the back. *Stam.* Filaments four, awl-ſhaped, erect, the length of the calyx, the two lower ones a little ſhorter; anthers oblong, heart-ſhaped, four-celled in front. *Piſt.* Germen ſuperior, quadrangular, gibbous, four-toothed; ſtyle erect, awl-ſhaped, in length and poſition like the ſtamens, ſtigma cloven into four ſegments, of which the upper one is the largeſt. *Peric.* Capſule quadrangular, four-lobed, with acute, diſtant angles; the cells inflated, their partitions open in the centre to admit the receptacle of the ſeeds, the valves burſting between the angles. *Seeds* four, ſomewhat globoſe, adhering to the centre of the capſule.

Eſſ. Ch. Calyx of five leaves; the lower one gibbous. Petals four. Nectary beneath the loweſt petal. Capſule four-celled.

1. M. *major*. Greater Honey-flower. Linn. Sp. Pl. 892. (M. africanus; Herm. Lugd. t. 415.)—Stipulas ſolitary, adhering to the leaf-ſtalk.—Diſcovered by Hermann at the Cape in the year 1672. It flowers in greenhouſes from May to July.—*Root* perennial, woody, ſpreading. *Stems* numerous, four or five feet high, herbaceous towards the top. *Leaves* pinnate, embracing the ſtem, greyiſh, compoſed of about three or four pairs of ovate, deeply-toothed leaflets, three or four inches long, with an odd one; a leafy, jagged border or wing running along the mid-rib connects them at their baſe. *Flowers* in a longiſh ſpike; ſpringing from between the leaves towards the top of the ſtalks, of a brown or chocolate colour.

2. M. *minor*. Leſſer Honey-flower. Linn. Sp. Pl. 892. Curt. Mag. t. 301.—Stipulas in pairs, but ſeparate. Cluſters axillary, elongated. Bracteas linear, tapering.—Native of the Cape, and cultivated in 1708 by the ducheſs of Beaufort.—*Stems* four or five feet high, branched, ſoft, round, woody. *Leaves* about half as large as in the preceding, green on the upper ſide, whitiſh beneath. *Flowers* ſix or eight in a cluſter, very ornamental, variegated with green, yellow and red or pink.—Mr. Curtis obſerves that the foliage when bruiſed has an unpleaſant ſmell; that the ſecreted honey or nectar does not flow ſo copiouſly from this as from the laſt which is more common, but that it exhibits rather an unuſual phenomenon, being retained in the lower part of the bloſſom, and of a dark brown colour.

3. M.

3. M. *comosus*. Tufted Honey-flower. Willd. n. 3. (M. africanus minor fœtidus; Comm. Rar. t. 4.)—Stipulas distinct. Clusters below the leaves. Flowers alternate. Bracteas heart-shaped. Leaves hairy above.—A native also of the Cape. *Stem* upright, branched, four feet high, round. *Leaves* pinnate, consisting of about five pairs of linear, deeply toothed, soft leaflets with an odd one, hoary underneath. *Flowers* in pendent clusters, on short stalks, of a yellow colour.

Melianthus, in *Gardening*, comprehends plants of the perennial exotic kind, of which the species cultivated are, the great honey-flower (M. major); and the small honey-flower, (M. minor.)

Method of Culture.—These two species of plants may be increased by suckers from the roots and cuttings of the young stalks or branches. The first sort is, however, best raised by planting the suckers, or side-shoots, any time in the spring or summer seasons, choosing such as are furnished with root fibres, in pots, or the places where they are to remain, which, after they are planted and have taken root, require little further care, but to keep them clean from weeds. The cuttings may be planted during any of the summer months, due water and shade being given. When they have taken root they should be planted out where they are to remain, or in separate pots, to be managed as green-house plants.

But the second sort is raised with more difficulty, and chiefly from cuttings, which should be planted upon an old hot-bed, the heat of which is over, and covered close with bell or hand-glasses to exclude the air. When they have taken root they may be planted out in pots, and sheltered in the winter under a frame for a year or two, till they are become strong, after which they may be set out in a warm border, and be managed in the same manner as the first sort. And they succeed best in a dry soil and warm situation; but some plants should always be kept in pots and treated as greenhouse plants, lest those in the open ground be destroyed by severe frosts.

All of them afford ornament and variety in the borders and clumps, as well as among other plants in greenhouse collections

MELIBŒA, in *Ancient Geography*, a town of Greece, in the part of Thessaly called Magnesia, about the precise situation of which authors differ. Strabo places it in a gulf, on the eastern coast, between mount Ossa to the N. and mount Pelion, somewhat farther from the coast, lying from N.W. to S.E.

MELIBŒUS Mons, a mountain of Germany, which, according to Cæsar (Bell. Gall. l. vi. c. 1.) formed a separation between the Cherusci and Suevi. It was part of those mountains which covered the forest Bacenis.—Also, a mountain of Italy.

MELICA, in *Botany*, a name supposed by Ambrosinus to be corrupted, either from *Miliaca*, which might express the likeness of the grass so called, to *Milium*; or from *Meline*, the name of some sort of *Panicum*, which it also resembles in the aspect and distribution of the blossoms.—Linn. Gen. 34. Schreb. 48. Willd. Sp. Pl. v. 1. 381. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 91. Ait. Hort. Kew. ed. 2. v. 1. 152. Juss. 31. Lamarck Illustr. t. 44. Gærtn. t. 80.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* A glume of two ovate, concave, nearly equal valves, containing two flowers. *Cor.* of two ovate awnless valves, one of which is concave, the other flat and smaller. A turbinate stalked body, consisting of two abortive florets, stands between the two perfect ones. Nectary of one fleshy horizontal leaf, surrounding the germen. *Stam.* Filaments three, capillary, thickened and united at their base, as long as the flower; anthers oblong, forked at each extremity. *Pist.* Germen superior, obovate, turbinate; styles two, bristle-shaped, spreading, naked at their base; stigmas oblong, feathery. *Peric.* none, except the corolla, which is not united to the seed. *Seed* one, ovate, with a longitudinal furrow at the upper side.

Obs. The stalked body between the florets is considered by Linnæus as affording an essential character. This consists of the abrupt rudiments of two other florets, placed in an alternate order, their glumes convolute and pellucid. To this Schrader adds that the stamens of the real florets are dilated and combined at their base, and that the *nectary* is of a single leaf.

Ess. Ch. Calyx of two valves, containing usually two florets, with the rudiment of more between them. Corolla of two valves, unconnected with the seed.

An elegant genus of grasses, of which Willdenow has thirteen species, three of them British. To these we add two gathered by Dr. Sibthorp in Greece, a third from America, and a fourth from the East Indies. The habit of the whole genus, well marked in some species, is not so uniform throughout the whole as could be wished. Neither is the number of perfect or of abortive florets constant in all.

1. M. *ciliata*. Fringed Melic-grass. Linn. Sp. Pl. 97. Sm. Fl. Græc. Sibth. v. 1. 54. t. 70. (Gramen montanum, avenæ semine; Clus. Hist. v. 2. 219.)—The outer petal of the lower floret fringed.—Native of dry stony ground in the south of Europe. With us it is sometimes kept in gardens for the sake of its long white plumpy spiked *panicles*. The *root* is perennial, tufted and knotty. *Stems* two or three feet high, erect, round, smooth, stiff, bearing several narrow rigid *leaves*. *Panicle* terminal, solitary, erect, close and cylindrical, from two to six inches long. *Calyx* containing only one perfect, and one abortive, floret. The *glumes* are membranous and whitish. *Stamens* long. *Fringe* of the corolla long, dense, and very remarkable.

2. M. *gigantea*. Gigantic Melic-grass. Thunb. Prod. 21. (Aira villosa; Linn. Suppl. 109.)—"Corolla hairy, awned. Panicle whorled. Stem erect."—Found by Thunberg at the Cape of Good Hope. The *root* is crowned with ovate-oblong hairy scales. *Stem* smooth. *Leaves* flat, tapering, with frequently shaggy sheaths. *Panicle* terminal, a foot long. *Florets* two, large, rusty; one of them smaller, and rather imperfect. *Corolla* hairy, with a short, straight, terminal awn.

3. M. *geniculata*. Bent-stalked Melic-grass. Thunb. Prod. 21.—"Corolla hairy. Panicle compact. Stem decumbent."—Native of the Cape.

4. M. *decumbens*. Decumbent Melic-grass. Thunb. Prod. 21.—"Corolla hairy. Flowers racemose, drooping. Stem decumbent."—From the same country. This must not be confounded with *M. decumbens* of Weber, which is *Festuca decumbens* of Linnæus, *Poa* of Fl. Brit. 107.

5. M. *racemosa*. Racemose Melic-grass. Thunb. Prod. 21.—"Corolla hairy. Clusters drooping. Stem erect."—From the Cape. We have seen no specimens of the last four species.

6. M. *minuta*. Slender Melic-grass. Linn. Mant. 32. Willd. n. 10. (M. pyramidalis; Desfont. Atlant. v. 1. 73. M. nutans; Cavan. Ic. v. 2. 58. t. 175. f. 2?)—Stem branched. Leaves setaceous. Petals beardless. Panicle simple, drooping.—Native of Italy, Spain, Greece and Cyprus.—This is an extremely slender smooth grass, scarcely a foot high. The *stems* are in our specimens, as Linnæus describes them, very much branched. Cavanilles says

says they are always simple. *Leaves* extremely narrow, perfectly setaceous when dry, from the inflexion of the edges; the long sheath crowned by a membranous *stipula*. *Panicle*, or rather *cluster*, simple, of a very few drooping flowers. The *calyx* contains two perfect florets, and the stalked rudiments of one or two others. All the *glumes* are obtuse and ribbed; the *corolla* minutely downy, but not fringed or bearded.

7. M. *saxatilis*. Rock Melic-grass. Sm. in Prod. Fl. Græc. Sibth. v. 1. 51. Fl. Græc. t. 71. (M. aspera; Desfont. Atlant. v. 1. 71? Gramen avenaceum saxatile, paniculâ sparsâ, locustis latioribus candicantibus et nitidis; Tourn. Inst. 524?)—Stem simple. Petals beardless. Panicle close, directed one way. Flowers drooping. Stipula elongated.—Frequent on rising ground in the islands of the Archipelago. It has the habit of the last, but is much larger in every part, and the *stems* are simple, *panicle* of a much greater number of *flowers*, with sharper glumes. The *panicle* agrees with that of the British *M. nutans*, hereafter mentioned, but the *foliage* is narrower, and the *stipula* more elongated than in that species. There is some reason to suspect the synonym of Cavanilles, which we have cited for the foregoing, may belong to this; but no stress can be laid on his delineations of the minuter parts.

8. M. *nutans*. Mountain Melic-grass. Linn. Sp. Pl. 98. Curt. Lond. fasc. 6. t. 4. Engl. Bot. t. 1059. Knapp. t. 42. Mart. Rust. t. 65. (M. montana; Huds. 37.)—Petals beardless. Panicle compact, leaning one way, nearly simple. Flowers drooping. Calyx two-flowered. Leaves flat.—Found in mountainous woods, chiefly in the north of Europe. With us it is confined to Westmoreland and the north-west part of Yorkshire, where it flowers in the early part of summer. The *root* is fibrous and perennial. *Stems* several, above a foot high, leafy, slender and naked above, with rough angles. *Leaves* lanceolate, flat, rough-edged, with a long rough sheath, and a very short jagged *stipula*. *Panicle* long, erect or slightly incurved, almost always simple, of many elegant purplish pendulous *flowers*, leaning one way. *Florets* two, with the unequal rudiments of two more. *Glumes* bluntish, with a white membranous termination. The *nectary* in this species answers to Schreber's description, but scarcely, we fear, in all.

9. M. *uniflora*. Wood Melic-grass. Retz. Obs. fasc. 1. 10. Curt. Lond. fasc. 5. t. 10. Engl. Bot. t. 1058. Knapp. t. 41. Mart. Rust. t. 64. (M. Lobelii; Villars Dauph. v. 1. 89. t. 3. M. nutans; Huds. 37.)—Petals beardless. Panicle branched, leaning one way. Flowers erect. Calyx single-flowered. Leaves flat.—Common in groves and bushy places in England and most parts of Europe, flowering in May and June, when its little red tumid flowers, trembling upon the divaricated wiry stalks of the panicle, make a very pretty appearance. The *root* is fibrous and perennial. *Stems* simple, a foot and half high, slender. *Leaves* flat and broadish, thin, bright green, rough at the back and edges, with a downy sheath and short variously-shaped *stipula*. *Panicle* of not many flowers; its lower branches two together. The single fertile *floret* is oval, tumid, with ribbed green glumes; the barren one likewise solitary, on a thick inflexed stalk.

10. M. *major*. Greater Melic-grass. Sm. Prod. Fl. Græc. Sibth. v. 1. 51. (M. n. 31; Gmel. Sib. v. 1. 99. t. 19. f. 1.)—Petals beardless. Panicle spreading; with branches in pairs. Flowers drooping. Stem simple. Leaves involute and pungent.—Native of Greece, France, and Siberia, in mountainous places. There is some reason to suspect this species to be what Dr. Sibthorp took for *M. nutans*, and put down as such in his lists of Greek plants, the latter not being found in his herbarium, nor this noticed by any other appellation. The plants however are very distinct. The *major* has a branched panicle, more like the *uniflora*, but the *calyx* contains from two to four florets, besides an abortive one, their *corolla* mostly bristly at the back. The *leaves* are flat when growing, but rolled in when dry, with a sharp rigid point. We believe this has been called *M. amethystina* by the abbè Pourret.

11. M. *ramosa*. Branched Cape Melic-grass. Thunb. Prod. 21.—“Petals smooth, beardless. Panicle compact. Stem branched.”—Gathered by Thunberg, at the Cape of Good Hope.

12. M. *capensis*. Spreading Cape Melic-grass. Thunb. Prod. 21.—“Petals smooth, beardless. Panicle widely spreading. Leaves nearly thread-shaped.”—From the same country. We have seen neither of these last, but their characters mark them as very distinct.

13. M. *papilionacea*. Fly Melic-grass. Linn. Mant. 31. Willd. n. 12. (M. brasiliana; Arduin. Spec. 2. 17. t. 6. f. 1, 2.)—Panicle close. Outer valve of the calyx very large, obovate, coloured. Outer petals with toothed ribs, somewhat hairy.—The seeds of this curious grass were sent from Brasil to Arduino, who raised them at Padua in 1756, and thinking it might form a new genus, as appears by his specimen, sent it to Linnæus, who justly referred it to *Melica*. Commerson gathered the same at Monte Video. The *stems* are eighteen inches high, simple, erect. *Leaves* broadish, somewhat involute in drying, their sheaths crowned by a long cloven *stipula*. *Panicle* branched, but compact. *Flowers* erect, remarkable for the large purple outer glume of their *calyx*, which embraces the whole of the spikelet, the inner glume being elevated on the stalk within, much narrower and more rigid, like the *corolla*, whose outer glumes have very strong, tuberculated, and somewhat hairy, ribs. The *florets* are two with one or two abortive ones.

14. M. *altissima*. Tall Melic-grass. Linn. Sp. Pl. 98. Host. Gram. Austr. v. 2. 8. t. 9. Ehrh. Calam. 71. (M. n. 30. Gmel. Sib. v. 1. 98. t. 20.)—Panicle close, many-flowered. Calyx-glumes obovate, nearly equal, rather shorter than the florets. Outer petals roughish, beardless. Leaves lanceolate, broad.—Native of Siberia. A tall and very handsome grass, with flat *leaves* half an inch in breadth, and a very long, upright, close, branched *panicle*, compound of innumerable crowded purple *flowers*, turned to one side. The above specific character distinguishes it from the last, which it much resembles at first sight.

15. M. *glabra*. Smooth American Melic-grass. Michaux Boreal-Amer. v. 1. 62. (M. altissima et mutica; Walt. Carol. 78? *Michaux*. Gramen avenaceum, locustis rarioribus muticis, virginianum majus; Moris. v. 3. 216. sect. 8. t. 7. f. 51.)—Panicle widely spreading, with branches in pairs. Flowers erect. Calyx-glumes elliptical, nearly equal, rather shorter than the florets. Petals smooth, beardless. Leaves linear.—Native of North America, from Virginia to Florida. *Michaux*. Linnæus referred the synonym of Morison to his *altissima*, having probably never seen the present species, which differs from that in its narrower *leaves*, spreading *panicle*, and smooth *flowers*. The *stem* is two or three feet high. Willdenow, who cites this as a variety of the last, still expresses his opinion of its being undoubtedly a different species.

16. M. *cærulea*. Purple Melic-grass. Linn. Mant. 2. 325. Ehrh. Calam. 91. Curt. Lond. fasc. 5. t. 11. Engl. Bot. t. 750. Knapp. t. 40. (Aira cærulea; Linn. Sp. Pl. 95. Huds. 33. Fl. Dán. t. 239.)—Panicle close, much branched. Flowers erect, cylindrical. Calyx-glumes much shorter than the florets. Petals acute, angular, smooth and beardless

beardlefs.—Native of various parts of Europe, generally on the moft barren fandy moors, or inundated heaths, flowering in Auguft. This is a very coarfe rigid ufelefs grafs, varying greatly in height and luxuriance according to the foil. Its habit is reed-like. *Leaves* taper-pointed and pungent, involute in drying, of a glaucous afpect, broad and fheathing at the bafe, with hairs in the place of a *ftipula*. *Panicle* erect, clofe, repeatedly branched, confifting of numerous, fmall, upright *flowers*, of a bluifh-purple hue, pale when growing in the fhade. *Calyx* of two unequal ovate, acute valves. *Florets* four, elongated, much exceeding the calyx, acute, angular rather than ribbed, fmooth and beardlefs, the two lower ones only complete and fertile. *Anthers* violet, almoft black. The habit of this is very diffimilar to all the foregoing, and its flowers in particular more refemble the next.

17. M. *diandra*. Broad-leaved Diandrous Melic-grafs. Roxb. MSS.—Panicle corymbofe, of numerous, flender, many-flowered branches. Flowers erect, ovate. Glumes all fharp-pointed, keeled, fmooth. Leaves ovato-lanceolate, reticulated.—Native of Calcutta. This has the habit of *Arundo Phragmites*. The *ftem* is clothed with feveral alternate, broad, lanceolate, acute *leaves*, fomewhat ovate at their bafe, with long, fringed, clofe *fheaths*. They have rough edges, and many ribs, connected by tranfverfe reticulations. The *panicle* is level-topped, compofed of numerous, flender, clofe, racemofe branches. *Flowers* purplifh, fhining, fmooth, rather fmaller, as well as more compreffed, than in the laft, all their glumes very fharp-pointed. By the name we prefume there are but two *ftamens*. The inner *petal* feems to be coarfely fringed, at leaft in the upper and imperfect floret.

M. *Falx*, Linn. Suppl. 109, is referred by Thunberg to *Cynofurus*, fee *C. Falcatus*, fp. 4. He is followed by Willdenow, and the habit as well as characters of this very curious grafs ftrongly juftify the meafure.

MELICA is alfo a word ufed by the ancients as the name of a food of a refrigerating and moiftening quality. It feems to have been a kind of *oxygala*; for Galen, when he directs perfons of a hot habit to ufe a refrigerating diet, among other aliments of that kind, directs the eating of melica, which, he fays, is prepared of milk. Conftantine, in his book of agriculture, mentions melica, and fays it was made by pouring milk into an earthen veffel, firft well impregnated with boiling hot vinegar, by means of which there was a feparation of the milk into whey and curd.

MELICE'RIA, or MELICÉRIOLA, in *Surgery*, a fmall encyfted tumour, the contents of which are of the confiftence of honey.

MELICE'RIS, (from μελι, *honey*, and κηρος, *wax*), an encyfted tumour, filled with matter, that has the appearance and confiftence of honey. See TUMOUR.

MELICHRUS, in *Botany*, from μελιχρος, *honey-coloured*, alluding, we prefume, to the colour of the flowers; efpecially as the mafculine gender is adopted in the fpecific names. Otherwife the latter would have been, as ufual, feminine, ποα, or *herba*, being underftood.—Brown. Prod. Nov. Holl. v. 1. 539.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of many leaves, erect, permanent; the five innermoft longeft, equal, lanceolate, concave. *Cor.* of one petal, wheel-fhaped, or pitcher-fhaped, in five equal fegments, bearded half way, and with five clufters of glands near its bafe. Nectary a glandular, nearly entire, cup, furrounding the bafe of the germen. *Stam.* Filaments five, thread-fhaped, equal, inferted into the bafe of the corolla; anthers incumbent, oblong, burfting lengthwife, flightly projecting. *Pift.* Germen fuperior, roundifh; ftyle columnar; ftigma capitate. *Peric.* Drupa nearly dry, with a hard fhell. *Nut* of five cells. *Seeds* folitary?

Eff. Ch. Outer calyx of many leaves. Corolla five-cleft, wheel or pitcher-fhaped, bearded half way, with five clufters of glands near the bafe. Drupa dry, of five cells.

This genus confifts of two fpecies of fmall *fhrubs*, which are procumbent, or nearly fo, with lanceolate *leaves*. The *flowers* are axillary, folitary, erect.

1. M. *rotatus*. Br. (Vintenatia procumbens; Cavan. Ic. v. 4. 28. t. 349. f. 1.)—Corolla wheel-fhaped. Calyx hairy. Leaves nearly linear, hairy on both fides and at the edges.—Native of New South Wales, as well as of the tropical part of New Holland. The *ftem* is much branched, procumbent. *Branches* clothed with feveral rows of imbricated, linear-lanceolate, acute, entire *leaves*, about an inch long, fomewhat glaucous, clothed and fringed with foft hairs, and ftriated with numerous ribs. *Flowers* numerous, axillary, folitary, feffile. *Calyx* loofely covered with long, foft, white hairs. Segments of the *corolla* acute, broad at the bafe; Cavanilles reprefents them much too narrow; each is bearded with long hairs from beyond the middle to the point. There appears to be more of a tube than properly belongs to a wheel-fhaped *corolla*, but our fpecimens are not fufficient to determine that point.

2. M. *urceolatus*. Br.—Corolla pitcher-fhaped. Calyx fmooth. Leaves lanceolate, taper-pointed, minutely toothed. —Gathered near Port Jackfon by Mr. Ferdinand Bauer.

The other fpecies of *Vintenatia*, *humifufa*, Cavan. Ic. v. 4. 28. t. 348, is referred by Mr. Brown to a diftinct genus, *Aftroloma*, Prod. Nov. Holl. v. 1. 538, in which the tube of the *corolla* is inflated, and twice the length of the *calyx*; its limb fhort, fpreading, bearded. Thefe differences are by no means ftrikingly indicated in Cavanilles' figures, nor do they there appear to us fufficient to divide plants in other refpects fo nearly alike. We can indeed judge but imperfectly from dried fpecimens, or from fuch delineations. Neither can we account for the fpelling of the name, which was intended to commemorate the late M. Ventenat.

MELICOCCA, from μελι, *honey*, and κοκκος, *a berry*, fo named by Dr. Patrick Browne from the fweetnefs or mellownefs of its fruit.—The Genip Tree.—Browne Jam. 210. Jacq. Amer. 108. Linn. Gen. 188. Schreb. 254. Willd. Sp. Pl. v. 2. 330. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 350. Swartz Obf. 144. Juff. 248. Lamarck Illuftr. t. 306. Gærtn. t. 42.—Clafs and order, *Octandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Sapindi*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of four, ovate, concave, obtufe, fpreading leaves. *Cor.* Petals four, oblong, equal, reflexed between the calyx-leaves. *Stam.* Filaments eight, awl-fhaped, erect, fhort; anthers oblong, erect. *Pift.* Germen fuperior, ovate, nearly the length of the corolla; ftyle very fhort; ftigma large, rather peltate, extended at each fide, oblique. *Peric.* Drupa covered with a tough fkin, roundifh, obtufely pointed. *Seed* a leathery, roundifh, fmooth nut.

Obf. In Gærtner's defcription of *Melicocca* the *Pericarp* is faid to be an ovate, pointed, leathery, thickifh *Berry*, of one cell. The *feeds* folitary (rarely two or three), ovate, furrowed on one fide, coated with a glutinous pulp.

Eff. Ch. Calyx deeply four-cleft. Petals four, reflexed between the calyx-leaves. Stigma fhield-like. Drupa with a tough coat.

1. M. *bijuga*. Genip Tree, or Honey-berry. Linn. Sp. Pl. 495. Jacq. Amer. t. 72. (Nux americana, foliis alatis bifidis; Comm. Hort. v. 1. 183. t. 94.)—A native of South America and cultivated in the Eaft Indies. Introduced into this

this country in 1778 by Dr. Thomas Clarke. We learn from Browne's History of Jamaica that this tree was brought to that island from Surinam. He calls it Genip tree from the Dutch *Knippen*. The Spaniards term it *Monos*. Jacquin mentions it as growing wild about Carthagena, and commonly cultivated at Curaçao. The *stem* of this tree rises to nearly twenty feet in height, and has numerous spreading branches. *Leaves* abruptly pinnate, on round, elongated, or rather compressed stalks, consisting of two pair of nearly sessile, ovate leaflets, acuminate at both ends, entire, nerved, smooth, bright green. *Flowers* in terminal, compound clusters of a yellow colour. *Fruit* about twice as large as a nutmeg, containing a sweet, acid, gelatinous substance like the yolk of an egg.

"Jacquin was informed at Curaçao that this genus was *diœcious*, but Swartz ascertained it to be *polygamous*, one tree bearing perfect flowers, another only male ones; the latter is most common and bears the finest flowers: they expand in April and the fruit ripens about Midsummer."

MELICOPE, a name constructed by Forster, from μελι, *honey*, and κοπη, *an incision*, the nectary being composed of a series of notched glands. Forst. Gen. t. 28. Schreb. 257. Willd. Sp. Pl. v. 2. 346. Mart. Mill. Dict. v. 3. Juss. 429. append. 453. Lamarck Dict. v. 4. 60. Illustr. t. 294. (Entoganum; Banks and Soland. MSS. Gærtn. t. 68.)—Class and order, *Octandria Monogynia*.—Nat. Ord. *Rutaceæ ?*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four deep, equal, roundish segments, permanent. *Cor.* Petals four, equal, ovate-oblong, with a little blunt point, keeled, broad at the base, slightly spreading. Nectary of four large cloven glands, encompassing the base of the germen. *Stam.* Filaments eight, awl-shaped, equal, simple, smooth, shorter than the petals, inserted into the receptacle on the outside of the nectary; anthers terminal, erect, oblong, somewhat heart-shaped, simple, of two cells. *Pist.* Germen superior, ovate, four-lobed; style quadrangular, short; stigma dilated, quadrangular, umbilicated. *Peric.* Capsules four, elliptical, compressed, spreading, of one cell, opening at the upper margin. *Seeds* solitary, compressed, smooth, stalked.

Eff. Ch. Calyx in four deep segments. Petals four. Nectary of four cloven glands round the germen. Stamens simple. Stigma dilated. Capsules four, single-seeded.

1. M. *ternata*. Forst. Prod. 28. (Entoganum lævigatum; Gærtn. v. 1. 331.)—Gathered by Forster in New Zeeland. The only known species. A *shrub*, with smooth, round, leafy *branches*; the young ones somewhat quadrangular. *Leaves* opposite, stalked, ternate; *leaflets* an inch or inch and a half long, obovate, bluntly pointed, very obscurely and irregularly crenate, rather thickened or bordered at the margin, tapering at the base, single-ribbed, with a few oblique forked veins, quite smooth, of a pale green when dry, full of small, pellucid, resinous dots; the terminal leaflet larger than the rest. Common *footstalk* about an inch long, linear, channelled, smooth. The lower *leaves* on each branch are simple, and smaller. *Stipulas* none. *Flower-stalks* axillary, solitary, shorter than the leaves, forked, or perhaps somewhat corymbose, smooth, slightly angular, with a pair of minute, concave *bracteas* at each subdivision. Whenever any of the stalks fall off, a broad pale peltate scar is left behind on the branch. *Flowers* about a quarter of an inch in diameter, white or yellowish, each on a quadrangular partial stalk, a quarter of an inch long, dilated upwards under the calyx. *Capsules* spreading in four directions, somewhat leathery, smooth, each a quarter of an inch long.

Of this very little-known shrub we have seen but one mutilated specimen, given by Forster to Linnæus. Nothing is said by the author of the genus, any more than by Solander or Gærtner, to indicate its affinity to any other, nor could Jussieu form even a conjecture on the subject. The shape, and resinous dots, of the leaves, as well as the pallid hue which they, like the other parts, assume in drying, and even the aspect of the flowers, whose petals are full of resinous dots, all seem to indicate the natural order of *Aurantia*. But these characters, except perhaps the pale colour, equally belong to the *Rutaceæ*, at least to those genera which are subjoined by Jussieu to that natural order, and of which *Diosma* is the type; and the fruit strongly confirms the propriety of referring *Melicope* to them. With these Jussieu was but slightly acquainted. There are numerous genera of this tribe in New Holland (see CORRÆA, CROWEA, ERIOSTEMON); as well as *Boronia*, Sm. Tracts 287. t. 4—7, and *Tetratheca*, Sm. Exot. Bot. t. 20—22. The inflorescence of the genus before us, as far as can be discovered from our bad specimen, seems very nearly that of *Boronia pinnata*, Andr. Repos. t. 58. Its simple filaments and anthers, and, according to Gærtner's description, the want of an *arillus* to the seeds, are circumstances in which it differs from *Boronia* and most of its allies. The flavour of the dried leaves is a little bitter, scarcely aromatic. S.

MELICUCCA, in *Geography*, a town of Naples, in Calabria Ultra; 10 miles W.S.W. of Oppido.

MELICYTUS, in *Botany*, so named by Forster, from μελι, *honey*, and κυτος, *a cavity* or *cell*, alluding to the five oblong bodies, hollowed out at their summits, which he conceived to be nectaries bearing the anthers. Forst. Gen. t. 62. Schreb. 685. Mart. Mill. Dict. v. 3. Juss. 428. Lamarck Dict. v. 4. 59. Illustr. t. 812. Gærtn. t. 44. Class and order, *Diœcia Pentandria*. Nat. Ord. *Euphorbiæ ?*

Gen. Ch. Male, *Cal.* Perianth very short, with five teeth. *Cor.* Petals five, equal, ovate, acute, widely spreading, longer than the calyx. Nectary of five club-shaped bodies, hollowed out at the top, erect, bearing the stamens at their inside. *Stam.* Filaments none, except the nectaries be so considered; anthers five, roundish-ovate, with four furrows in front, attached lengthwise to the inner side of the nectaries, and extending slightly beyond them.

Female, *Cal.* and *Cor.* as in the male. Nectary of five triangular acute scales, shorter than the calyx, surrounding the germen closely at its base. *Pist.* Germen ovate; style none; stigma of four or five small, flat, rounded lobes. *Peric.* Capsule pulpy, globose, smooth, coriaceous, of one cell, with four or five valves. *Seeds* about five, convex on one side, angular on the other, lodged in pulp.

Eff. Ch. Male, Calyx with five teeth. Petals five. Nectary of five hollow-tipped bodies, bearing the stamens.

Female, Cal. and Cor. as in the male. Nectary of five scales round the germen. Stigma sessile, four or five-lobed. Capsule pulpy, of one cell and five valves. Seeds five.

1. M. *ramiflorus*. Forst. Prod. 70.—Native of the neighbourhood of Queen Charlotte's Sound, New Zeeland, flowering there in November. A *shrub*, or *tree*, with round, smooth, leafy *branches*. *Leaves* deciduous, scattered, on short smooth footstalks, elliptic-lanceolate or obovate, obtuse, bluntly serrated, smooth on both sides, with one rib and numerous interbranching reticulated veins, each leaf an inch and a half or two inches long, and nearly one broad. *Flower-stalks* several together, from scattered lateral or axillary buds, each about a quarter of an inch long, swelling upwards, simple, smooth, bearing about the middle a minute fringed concave *bractea*, single-flowered. *Flowers* very minute, whitish.

Jussieu knew not where to place this genus in his natural orders, but was led by its artificial characters, as it seems, to to fuppofe it akin to *Aftronium* of Jacquin and Linnæus. Gærtner having the fruit, which Forfter knew nothing of, more happily perceived its relationfhip to KIGGELARIA. (See that article, and ASTRONIUM.) This relationfhip has induced us to refer *Melicytus* to the *Euphorbiæ* of the great French botanift, notwithftanding the prefence of petals, which that natural order, it feems, ought to be without. We cannot however be fo far led by hypothefis as to deny real petals to *Kiggelaria*.

MELIDES, in *Geography*, a town of Portugal, in the province of Eftramadura; 21 miles S. of Setuval.

MELILITE. This fcarce mineral fubftance has hitherto been found only in minute but very regular cubic or parallelepipedic cryftals: they are of the fize of a millet feed, of a yellow colour, and externally covered by a brownifh or gold yellow cruft of iron ochre. Their hardnefs is fufficient to fcratch fteel.

The melilite melts before the blowpipe, without effervefcence, into a tranfparent folid glafs of a greenifh colour. Its powder forms a tranfparent jelly with nitric acid. It is not pyro-electric.

By thefe characters this microfcopic mineral is fufficiently diftinguifhable from mefotype, ftilbite, chabafie, and analcime, to which it bears fome diftant refemblance.

The cubic cryftals of the melilite pafs into the cuneiform octahedron.

Thefe fmall cryftals were difcovered by M. Fleurieu de Bellevue in the fiffures of a black, pretty compact lava, known under the name of *felce romano*, found at Capo di Bove, near Rome. They are accompanied by fmall, white, tranfparent, acicular cryftals, which appear to belong to fommite or nepheline. Brongn.

MELILLA, or MELELA, in *Geography*, a town of Africa, in the kingdom of Fez, fituated on the coaft of the Mediterranean, and belonging to the Spaniards. It was probably founded by the Carthaginians, and feems to have derived its name from the honey produced in its environs. The town is ftrongly fortified and furrounded by the fea. The only communication with the main land, inhabited by the Moors, is by a draw-bridge. It was abandoned by the Goths when the Arabs invaded the country, and being deferted by the Moors, was feized on by the Spaniards about the beginning of the 15th century. This town has large magazines and cifterns for preferving the water. The number of inhabitants is eftimated at 2000; 140 miles E. of Tetuan. N. lat. 35° 24'. W. long. 2° 54'.

MELILLI, a town of Sicily, fituated on mount Hybla, famous for its excellent honey, to which it owes its name; as well as alfo to the fertility of the adjacent territory, or the fugar-canes once cultivated there, but now abandoned.

MELILOBUS, in *Botany*, (from μελι, *honey*, and λοβος, *a pod*, or *legume*, alluding to the fweet pulp in which the feeds are lodged,) the original name given by Mitchell to the *Gleditfia* of Clayton and Linnæus, and undoubtedly a very expreffive one. It is much to be wifhed that fuch fhould always have a preference; and that no genus fhould ever be confecrated to any botanift, till an expreffive name, of Greek or Latin derivation, had firft been fought in vain. But alas! this is like wifhing for honefty and difintereftednefs in thofe who elect, and thofe who are elected.

MELILOT, a fpecies of trefoil, or *trifolium*; which fee. (See MELILOTUS.) This plant grows wild in moft parts of Europe, in corn-fields, paftures, and by way-fides. Among bread-corn it is a troublefome weed; and ripening about the fame time with the corn, is often ground with it, being difficult to feparate from it: in fuch a cafe it fpoils the bread, or whatever the flour is ufed for, by giving it a ftrong tafte, like the plafter made from it.

Melilot is fcarcely ever given internally; but ufed externally, it was formerly efteemed emollient and digeftive, and was employed as an ingredient in cataplafms, fomentations, and blifter-plafters; but it is now laid afide as being rather acrid and irritating than emollient. The flowers have been recommended by fome in infufion, in the manner of thofe of chamomile, as a remedy for the fluor albus. It formerly gave the name to one of the officinal plafters, which received from the melilot a green colour and an unpleafant fmell, without any addition to its efficacy.

MELILOTUS, μελιλωτος of Diofcorides, appears to be the *Trifolium Melilotus-officinalis* of Linnæus, which Dr. Sibthorp found growing wild, in low moift fituations, in Attica and different parts of Greece. This ingenious and learned traveller fufpected the other kind, which is mentioned by the above Greek writer as of a yellower colour and weaker fcent, and growing about Nola in Campania, might be *T. Melilotus-italica*, which is found on the dry ground of Mount Hymettus, near Athens. Dr. Sibthorp obferved the figure in the famous ancient manufcript at Vienna, to be evidently intended for one of thefe fpecies.

MELIN, in *Geography*, a town of Croatia; 12 miles S.S.W. of Varafdin.

MELINDA, a kingdom of Africa, fituated near the coaft of the Indian fea. This country is for the moft part fertile, producing almoft all the neceffaries of life, except wheat and rice, for want of which, thofe who cannot purchafe them are fupplied with potatoes, which are here large and plentiful. They abound with other roots and fruits, and with melons of excellent quality. Citrons here are abundant, and agreeably perfume the air during the greateft part of the year. They have alfo plenty of venifon, game, oxen, fheep, geefe, and other poultry; and a breed of fheep, whofe tails weigh in general between twenty and thirty pounds. The men are black, fwarthy, tawny, and white, and the women chiefly of an olive colour; their drefs is elegant, confifting of fine filks, girt with rich gold or filver girdles, collars, and bracelets, and their heads are covered with veils. The men wear a kind of turban; and in other refpects their drefs confifts of a piece of cotton wrapped round the middle, and reaching below the knees, the other parts of the body being naked. Thofe of the meaner clafs, and fuch as live in the interior of the country, wear little elfe befides a piece of cloth about their middle, except their fhield and military weapons, which are the bow and arrows, the fcymetar, and the javelin. Their religion is chiefly Mahometan; with a mixture of idolaters; and their government is monarchical, the king being treated with great refpect and veneration by his fubjects: and accompanied with attendants, who prefent him with incenfe and perfumes, whenever he goes abroad, and ladies who pay their homage to him with fongs and feveral kinds of mufical inftruments. The prince of this country was formerly tributary to the Portuguefe; but they are now obliged to purchafe, by annual prefents, permiffion to trade, and to fearch for gold. Adjoining to Melinda are five other kingdoms, to which the connection and influence of the Portuguefe extend. The natives, befides their commerce with the Portuguefe, carry on fome trade with their own veffels, in which they frequent the Red fea, and Arabian ports; and they fometimes traverfe the Indian feas, as far as Cambaya, in the territories of the great Mogul. On the other hand, the Arabians and Indians bring goods to Melinda: but the whole trade, which is little inferior to that of Mozambique, is ultimately tranfacted with the Portuguefe.

tuguefe. The articles brought to Melinda are gold from Sofala; as well as ivory, copper, quickfilver, all forts of filks and cottons from Europe and the Eaft Indies, together with fpices, rice, and other grain.

Melinda, the capital of the above-defcribed kingdom, pleafantly fituated on a beautiful plain near the coaft of the Indian fea, and furrounded by fine gardens and orchards, producing all forts of fruit-trees, efpecially citrons and oranges. The houfes are built of fquare ftone, many of them being conftructed in a magnificent ftyle, and all richly furnifhed, for the ftated refidence of rich merchants, and the occafional refort of foreigners, who carry on an extenfive commerce in gold, copper, quickfilver, ivory, wax, and drugs, in exchange for filk, cottons, linen cloths, corn, and other commodities. The harbour is difficult of accefs, on account of rocks and fhelves that intercept the approach to it, and oblige veffels to come to anchorage at fome diftance from it. The warehoufes at Melinda fupply the country with European goods to a great diftance within land, where they procure vaft quantities of ivory. This city was wholly built by the Portuguefe, and is faid to contain 30,000 Portuguefe, befides natives; and includes feventeen Chriftian churches, together with other religious houfes. S. lat. 3° 5'. E. long. 42° 40'.

Melinda, one of the Querimba iflands, in the Indian fea. S. lat. 10° 30'.

MELINGEN, a town of Switzerland, on the Rufs; 43 miles N.E. of Berne. N. lat. 47° 10'. E. long. 8° 15'.

MELINUM, in *Natural Hiftory*, the name of an earth, famous in the earlieft ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the colours with which alone they performed all their works.

It is a fine white marly earth, of a very compact texture, yet remarkably light; a fort of texture which muft render any earth fit for the painter's ufe, that is of a proper colour. It is frequently found forming a ftratum in the earth, lying immediately under the vegetable mould. It is of a very fmooth, but not gloffy furface; is very foft to the touch, adheres firmly to the tongue, is eafily broken between the fingers, and ftains the fkin in handling. It melts readily in the mouth, and is perfectly fine, leaving not the leaft grittinefs between the teeth. Thrown into water, it makes a great bubbling and loud hiffing noife, and moulders away into a fine powder. It does not ferment with acids, and fuffers no change in the fire. Thefe are the characters by which the melinum of the ancients is diftinguifhed from all the other white earths. It is ftill found in the fame place from whence the painters of old had it, which is that from whence it has its name, the ifland of Milo, called Melos by the Greeks, and is common in moft of the adjacent iflands. It has been of late tried here as a paint, and is found not to make fo bright a white as the other fubftances now in ufe among the painters, but feems not liable, like them, to turn yellow; and if fo, would be worth the confideration of perfons in the colour-trade, efpecially as it may be had in any quantities for carriage.

MELINUS Color, Μηλινον χρωμα, in *Antiquity*, a colour often mentioned in fpeaking of the habits of players. It was a reddifh-yellow, of the colour of ripe apples, in Greek called μηλα, and their colour μηλοειδες χρωμα.

MELIPILLA, in *Geography*, a town of South America, and capital of a jurifdiction in the kingdom of Chili; 42 miles S.E. of Valparaifo. S. lat. 33° 28'. W. long. 70° 7'.

MELIPU, a river of Ceylon, which runs into the fea near Matara.

MELIS, a town of Germany, in the principality of Gotha; 16 miles S. of Gotha.

MELISANA, a town of Italy, in the country of Friuli; 6 miles S. of Palma Nuova.

MELISEY, a town of France, in the department of the Upper Saone, and chief place of a canton, in the diftrict of Lure. The place contains 1499, and the canton 10,130 inhabitants, on a territory of 187½ kiliometres, in 12 communes.

MELISMATICO Stylo. See Style.

MELISSA, in *Botany*, from μελισσα, the Greek name of a bee; or rather, as that name itfelf, like the ancient proper names *Meliffa* and *Meliffus*, alfo originated from μελι, *honey*, becaufe of the abundant and excellent honey of the flowers of this herb, for which bees are faid greatly to frequent them.—Balm.—Linn. Gen. 298. Schreb. 394. Willd. Sp. Pl. v. 3. 146. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 416. Juff. 115. Tourn. t. 92. Lamarck Dict. v. 4. 76. Illuftr. t. 512. (Horminum; Linn. Gen. 299. Juff. 116. Lamarck Dict. v. 3. 136. Illuftr. t. 515.)—Clafs and order, *Didynamia Gymnofpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, nearly bell-fhaped, rather dry and fcariofe, fomewhat gaping, angular, ftriated, permanent, its mouth two-lipped; *upper lip* three-toothed, bent backwards, flat; *lower* fhorter, fharpifh, deeply cloven. *Cor.* of one petal, ringent; *tube* cylindrical; mouth gaping; *upper lip* fhorteft, erect, vaulted, roundifh, cloven; *lower* three-cleft, the middle fegment largeft and heart-fhaped. *Stam.* Filaments four, awl-fhaped, two of them the length of the corolla, two but half fo long; anthers fmall, cohering in pairs. *Pift.* Germen four-cleft; ftyle thread-fhaped, the length of the corolla, curved with the ftamens under the upper lip of the corolla; ftigma flender, cloven, reflexed. *Peric.* none, except the enlarged, but otherwife unaltered calyx. *Seeds* in the bottom of the calyx, four, ovate.

Eff. Ch. Calyx fcariofe, flattifh on the upper fide; its upper lip with three nearly level-pointed teeth. Upper lip of the corolla fomewhat vaulted, cloven; middle lobe of the lower lip heart-fhaped.

1. M. *officinalis*. Common Garden Balm. Linn. Sp. Pl. 827. Sm. Prod. Fl. Græc. Sibth. v. 1. 423. Stokes Mat. Med. v. 2. 365. Woodv. Med. Bot. t. 147. (Meliffa; Ger. em. 689. Apiaftrum five Meliffa; Matth. Valgr. v. 2. 181.)—Whorls halved. Bracteas oblong, ftalked. Leaves ovate, acute, ferrated.—Native of the mountains of Geneva, Savoy, and Italy. Dr. Sibthorp found it in fhady woods upon Mount Parnaffus, where it is ftill called μελισσόχορτον, or Balm-plant, which confirms the general opinion of its being the μελισσοφυλλον of Diofcorides, who mentions the lemon-like fcent for which this herb is fo remarkable, and on account of which it is fo generally ufed to make a grateful cooling infufion for perfons in fevers. In this fcent it much agrees with the more powerful *Verbena triphylla*, brought from Peru by the unfortunate Dombey, fee his life in its proper place. The *root* of this *Meliffa* is fibrous and perennial. *Stems* feveral, two or three feet high, leafy, fomewhat branched, acutely quadrangular, hairy and harfh to the touch. *Leaves* oppofite, ftalked, ovate, or very flightly heart-fhaped, ferrated, fomewhat hairy, ftrongly veined, an inch and half long. *Flowers* axillary, in halved whorls, leaning toward one fide; their ftalks downy, accompanied by fmall, oval, generally feffile *bracteas*. *Calyx* hairy. *Corolla* twice as long, white or pale-purplifh.

2. M. *altiffima*. Tall Greek Balm. Sibth. in Prodr. Fl. Græc. v. 1. 423.—Whorls halved, ftalked. Bracteas ftalked,

ſtalked. Leaves heart-ſhaped, ſharply crenate.—Common in ſhady ſituations in Greece, eſpecially under hedges, as well as in Crete. *Sibthorp.* This was ſuſpected by Dr. Sibthorp to be the third καλαμινθη of Dioſcorides, but that point is ſcarcely to be ſettled with any probability. Neither are we fully ſatisfied of our preſent plant being ſpecifically diſtinct from the firſt. By the ſpecimens and figure, which laſt is deſtined for *t.* 579 of the *Flora Græca*, it appears to be a taller and larger herb, with rather more heart-ſhaped *leaves*, and the *whorls* as well as *bracteas* are elevated on more evident ſtalks. The *flower* is repreſented white, with a pale pink upper lip; the lower lip hairy on the upper ſide near its baſe, its middle lobe broadeſt, but by no means heart-ſhaped.

3. M. *grandiflora*. Great-flowered Balm. Linn. Sp. Pl. 827. Curt. Mag. t. 208. (Calamentha flore magno; Riv. Monop. Irr. t. 46. f. 1. C. montana præſtantior; Ger. em. 687.)—Flower-ſtalks axillary, forked, longer than the footſtalks. Bracteas lanceolate, ſeſſile. Leaves ovate, ſerrated.—Native of hilly ground in Greece, Italy, and Germany. Gerard cultivated this ſpecies here in 1596, and it may ſtill be frequently ſeen in gardens, being, as Curtis obſerves, ſuitable for the decoration of rock-work. It thrives beſt in dry gravelly ground, and is perennial, flowering throughout the ſummer. *Root* fibrous. *Stems* about a foot high, weak and ſpreading. *Leaves* ovate, hairy. *Flowers* from three to ſeven on each long axillary ſtalk, with ſeveral ſmall ſeſſile *bracteas*. *Corolla* large, light crimſon, with a white ſtreak, and ſpots on the lower lip. The whole plant has a much more powerful ſcent than *M. officinalis*, without any of the lemon flavour.

4. M. *pyrenaica*. Pyrenean Balm. Jacq. Hort. Vind. v. 2. 86. t. 183. (M. pyrenaica, caule brevi, plantaginis folio; Tourn. Inſt. 193. Magn. Hort. 133. t. 17. Horminum pyrenaicum; Linn. Sp. Pl. 831.)—Stem leafleſs. Flowers whorled, turned to one ſide. Leaves oblong, bluntly toothed.—Native of the higheſt mountains among the Pyrenees, in the Tyrol and Carniola. We have ſeen it in no garden, but Jacquin cultivated this plant at Vienna. He was led by Scopoli to refer it to *Meliſſa*, inſtead of making it a diſtinct genus, as Linnæus had done. The *root* is long, woody, black, and perennial, flowering about the third year from the ſowing of the ſeed, in June. *Leaves* ſeveral, all radical, oblong or ſomewhat ovate, veiny, ſmooth, ſtrongly and bluntly toothed, decurrent at the baſe, on long ſtalks. *Flower-ſtalks* ſolitary, about a foot high, bearing ſeveral pairs of oppoſite, ovate, entire *bracteas*, and in the upper part numerous bracteated *whorls* of ſimply-ſtalked *flowers* leaning to one ſide. The *Corolla* is dark blue, about an inch long, handſome, more bell-ſhaped than in the foregoing, with ſhorter lips in rounded ſegments.

Such are all the genuine *Meliſſæ* known to us. The *M. Calamintha*, *Nepeta*, *cretica* and *fruticoſa* of Linnæus appear to us by their habit, as well as by the hairs which cloſe the mouth of the calyx, to belong to *Thymus*, to which genus the two firſt are referred in the *Flora Britannica*. It happened however that Willdenow did not receive this laſt-mentioned work, till he had written his *Sp. Pl.* as far as *Tetradynamia*, and as the *Hort. Kew.* generally follows him, theſe ſpecies continue there as they were. Indeed the ſubject is not without difficulty, as *M. officinalis* has ſome diſtant hairs in the mouth of the calyx; but its reflexed upper lip, with three teeth of equal height, is unlike that of the four ſpecies above named, though, we confeſs, too ſimilar in that reſpect to ſome kinds of *Thymus*. The middle ſegment of the lower lip of the corolla, ſuppoſed to be heart-ſhaped in *Meliſſa* and entire in *Thymus*, we find as little to be depended on as any of the above marks.

Melissa, in *Gardening*, comprehends plants of the hardy herbaceous, fibrous-rooted perennial kind, of which the ſpecies cultivated are, the officinal, or common garden baum or balm (M. officinalis); the great-flowered baum (M. grandiflora); the Cretan baum (M. cretica); and the ſhrubby baum (M. fruticoſa): as to theſe two laſt ſuppoſed ſpecies, ſee the laſt article.

The firſt ſort varies occaſionally with variegated leaves, and with the ſtalks ſlender, the leaves much ſhorter, the whole plant hairy, and of a ſtrong diſagreeable odour, the flowers in whorls, ſitting pretty cloſe to the branches, and ſmaller than thoſe of the common ſort; and has the name of Roman baum.

In the ſecond ſpecies there are varieties with white flowers, with red flowers, and with variegated leaves; but they are all inferior to the purple.

Method of Culture.—The two firſt ſorts may be readily increaſed by parting the roots, and planting them out in the early autumn, as October, time enough for the offſets to be eſtabliſhed before the winter froſts come on. They ſhould be divided into ſmall pieces, with three or four buds to each, and the firſt ſort planted two feet a-part, in beds of common garden earth, and the ſecond ſort in the borders or other parts ſingly, in larger offſet ſlips. The only culture they afterwards require is to keep them clean from weeds, and to cut off the decayed ſtalks annually in autumn, digging or ſtirring the ground between the plants in the common kind very well.

The third ſpecies may be raiſed by ſowing the ſeeds in the autumn or ſpring, but where the ſeeds are permitted to ſcatter, there will be a ſufficient ſupply of young plants without any further trouble.

And the fourth ſpecies may alſo be increaſed by ſeeds ſown in the ſpring on beds or in pots, or by cuttings planted in the ſame manner, in any of the ſummer months, and ſhaded from the ſun. They frequently live through the winter in warm borders; but it is always proper to keep a plant or two in pots, ſheltered under a frame during that ſeaſon, to prevent accidents.

In reſpect to the firſt ſort, it is uſeful for various domeſtic purpoſes, and the others ornamental, in the borders, clumps, and other parts, as well as affording variety among potted plants in many caſes.

Melissa *Officinalis*, *Common Balm*, in the *Materia Medica*. The herb, in its recent ſtate, has a weak, roughiſh, aromatic taſte, and a pleaſant ſmell, ſomewhat of the lemon kind: and hence this ſpecies has been denominated "Meliſſa odore citri." On diſtilling the freſh herb with water, it impregnates the firſt runnings pretty ſtrongly with its grateful flavour: and when large quantities are employed in this way, there ſeparates and riſes to the ſurface of the aqueous fluid a ſmall portion of eſſential oil, in colour yellowiſh, and of a very fragrant ſmell. Balm was formerly eſteemed of great uſe, in all complaints ſuppoſed to proceed from a diſordered ſtate of the nervous ſyſtem, and it was very generally recommended in melancholic and hypochondriacal affections, ſo that, in the opinion of Paracelſus, the "primum ens Meliſſæ" promiſed a complete renovation of man. Hoffmann and Boerhaave inclined to the opinion of the Arab phyſicians, and deemed it an efficacious remedy. S. Paulli and others ſpeak of its effects as an emmenagogue: but neither this nor any other medicinal power is now attributed to balm. As tea, however, it makes a grateful diluent drink in fevers, and in this way it is commonly uſed, either by itſelf or acidulated with lemons. The eſſential oil probably poſſeſſes no qualities different

ferent from many other aromatics and cordials. Lewis and Woodville.

Melissa, in *Geography*, a town of Naples, in Calabria Citra; 4 miles N. of Strongoli.

MELISSOPHYLLUM, in *Botany*. See Melittis.

MELISSUS, in *Biography*, a philosopher of Samos, of the Eleatic sect, who flourished about the eighty-fourth Olympiad, or the year 440 B.C. He was a disciple of Parmenides, to whose doctrines he closely adhered. As a public man, he was conversant with affairs of the state, and acquired great influence among his countrymen, who had a high veneration for his talents and virtues. Being appointed by them to the command of a fleet, he obtained a great naval victory over the Athenians. As a philosopher, he maintained that the principle of all things is one and immutable, or that whatever exists is one being; that this one being includes all things, and is infinite, without beginning or end; that there is neither vacuum nor motion in the universe, nor any such thing as production or decay, that the changes which it seems to suffer, are only illusions of our senses, and mere appearances; and that we ought not to lay down any thing positively concerning the gods, since our knowledge of them is so uncertain. Themistocles is said to have been of the number of his pupils. Enfield's Hist. Phil.

MELISTAURUM, in *Botany*, so called by Forster, from μελι, *honey*, and ςαυρος, *a stake*, or *a row of sharp pales*, the nectary bearing a resemblance to a circular fence of that kind. This author declares the genus to belong to *Polygamia Dioecia*, and professes to describe a male flower only, having never seen the hermaphrodite ones. How he ascertained the existence of such, without having seen them, in a plant known to himself alone, does not appear. In his Prodromus, p. 93, this is ranged among the obscure plants, of which he had seen imperfect specimens only, by the name of *Melistaurum distichum*, and said to be a native of New Caledonia. The male flower is figured in his *Genera*, t. 72, and thus described.

" *Cal.* none, unless the corolla be taken for such. *Cor.* minute, in five deep, roundish, concave, spreading segments. Nectary bell-shaped, abrupt, inserted into the corolla, bearing the stamens on its margin. *Stam.* Filaments twenty, inserted into the edge of the nectary, alternately awl-shaped, with roundish anthers, and of a thicker shape, hairy at the top, without anthers. *Pist.* Germen thickish, in the centre of the flower; style cylindrical, short; stigma blunt. *Peric.* and *Seeds* unknown, as well as the hermaphrodite flowers." *Forster.*

Every reader must perceive this to be the description of an hermaphrodite flower; so that we apprehend some misapplication of terms. However this may be, the description and figure are sufficient to justify Jussieu, who in his *Genera*, p. 438, refers Forster's plant to his own *Anavinga*, Lamarck Illustr. t. 355, which is *Casearia*, Schreb. Gen. 298, nearly allied to the *Samyda* of Linnæus. See Anavinga and Casearia.

MELITA, in *Ancient Geography*, an island in the Mediterranean, concerning which geographers have entertained different opinions. Ptolemy places it very near to Africa. Silius Italicus gives it the epithet of " Lanigera" on account of its wool. Cicero speaks of a temple of Juno, which was in this island, situated near a town of the same name. As it was upon an island of this name that St. Paul was shipwrecked, in his voyage to Rome, after his appeal to Cæsar (see Acts, chap. xxvii. and xxviii.), the situation of this island has been the subject of curious and diligent investigation. But no person has employed more labour and more learning in the research than Mr. Bryant. In the history, we find, that having been tossed for some time in the Adria, they were at last cast upon the island called Melite. The only question is, which is the sea, called Adria or Adriatic; and what island can be found in that sea under this name. The Adriatic sea is that large gulf which lies between Italy and the ancient Illyria, and retains its name to this day. And as to the island we are seeking, there was one in that sea called " Melite," which is mentioned under that name by the best geographical writers. It appears from ancient authorities, that Melita was an Illyrian island in the Adriatic sea; and that it lay between Corcyra Nigra and the main land, very near the river Naro and the isthmus above it. It was called by the ancients Melite, Melitene, and Melitassa; at this day it is denominated Meleda, and by the Sclavonians, Mlect, and is in the jurisdiction of Ragusa. Nevertheless it has been the common opinion, that the Melita, now called Malta, was the true place of the apostle's shipwreck; and the natives have a tradition of long standing to support this notion. Mr. Bryant, however, undertakes to prove, that this could not be the island mentioned by the writer of the book of Acts. But in doing this he contends with a host of learning and criticism; Grotius, Cluver, Beza, Bochart, and Bentley. In order to support this opinion, it is necessary for them to prove that Malta is an Adriatic island. This Bochart has much laboured to do; depending upon the authority of the poets, and a few of the later historians, who have extended the Adriatic to the coast of Africa. Polybius, Diodorus, Strabo, and Pliny, give a very different account of this matter. Mr. Bryant, after having fairly and fully stated the arguments of Bochart in favour of Malta, in his own words, undertakes to produce incontestible proof that Malta was not the place mentioned by the sacred historian, and that Melita Illyrica was. It must be allowed that, by the aid of the most approved geographers and historians, he has produced very strong, and to us satisfactory evidence, that the Adriatic sea was comprehended within the great Illyrian gulf, and never reached farther. Strabo expressly determines its extent by two fixed boundaries, that cannot be mistaken; it was included between Italy and the opposite continent. " Where then," says our author, " was St. Paul shipwrecked? Certainly between Italy and Illyria, that is, the opposite continent. Is Malta to be found in this situation? It is far off, in a sea that has no affinity, no connection with those coasts. But the other Melita, taken notice of by Scylax, Agathemerus, and Pliny, is situated in the Adria, agreeable to the apostle's account; therefore, Melita Illyrica is certainly the island there mentioned." Mr. Bryant strengthens his other arguments by adverting to the character of the natives, who are described as Βαρβαροι, barbarians. This character could not consistently be applied to the inhabitants of Melita Africana (Malta), which was first colonized by Phœnicians, and afterwards inhabited successively by Carthaginians, Greeks, and Romans. " Who will be so hardy as to denominate any of these nations barbarous? They were each of them renowned for arts, of great power and wealth, and of particular elegance and refinement. As the ancestry was good, the posterity did not fall off. The testimony of Diodorus Siculus (Hist. Bibl. l. v.) will sufficiently vindicate them from the charge of being barbarous. We have an account of some remains of antiquity in this island that will serve to guide our judgment concerning this people. The temples of Juno and Hercules appear to have been very magnificent, and of great extent: and the coins that were originally struck there are said to be of no ordinary cast. Nor can it be said that those even of the lower class were rude and savage; because from them St. Paul experienced nothing but civility. But if we take a view of Melita Illyrica, the scene will be changed, and the appellation will be found to be more applicable. The character of the Illyrians, near whom this island was situated, is represented as barbarous beyond measure. Modern travellers report of Malta that it harbours no serpents; a blessing, we are told, bequeathed to the island by St. Paul at his departure. If this be true of Malta, what is allowed as a test of the apostle's having been upon the island, is a proof to me, says our author, that he never was there. As there are no serpents now, my conclusion is, that there never were any; and consequently it could not be the place where St. Paul exhibited the miracle. For other particulars we must refer to Mr. Bryant himself. Bryant's Observations and Inquiries, &c. 1767, 4to.

MELITENE, Meledni, a country of Asia, in Armenia Minor, which extended to the right of the Euphrates, and was traversed by the river Meles.—Also, a town of Cappadocia, to the S.E., upon a stream which discharged itself into the river Meles.—Also, a country of Asia, in Cappadocia, occupying the S.E. part of it.

MELITENSIS Terra, *Earth of Malta*, in the *Materia Medica*, an earth of which there are two very different kinds, the one of the genus of the boles, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use: but both being brought from the same place, are confusedly called by the same name.

The Maltese bole, which is what we use now, is a fine earth, of a close compact texture, very heavy; when dug it is of a very pure white, but it is apt to contract a yellowness in drying, and become of a cream colour. It is of a very smooth and shining surface, scarcely at all stains the skin in handling, adheres strongly to the tongue, and melts into a butter-like substance in the mouth. It makes no effervescence with aquafortis, or any other acid menstruum, and suffers no change of colour in the fire. Hill. For the character of boles, see Boles. The Maltese marle, which is the terra Melitensis of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and when exposed to the weather, soon falls into fine soft powder; but when preserved and dried, it becomes a loose light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into water it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums.

Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals, but with how much justice we cannot say. The other has supplied its place in the German shops, and is used there as a cordial, a sudorific, and astringent. For the character of marles, see Marle.

MELITIA, in *Geography*, a town of European Turkey, in Thessaly; 24 miles S. of Larissa.

MELITITES, Μελιτιτης, in *Natural History*, an indurated clay, of a yellowish colour, but in many respects approaching to the nature of the morocthus or French chalk: which, when pulverized, yields with water a milky liquor, of a taste somewhat like honey: whence it takes its name.

It is a smooth substance, of a compact texture and great weight, of a fine, even, glossy surface, smooth and soft to the touch, does not adhere to the tongue, nor stain the fingers; but drawn along a rough surface, leaves a fine slender white line, and shaved into very thin pieces, has some degree of transparence. It does not ferment with acids, and burns to a pure white.

It is found in mines of metals, and seems to partake pretty much of the nature of lead; having a sweetness somewhat like that of the sal saturni, but much fainter. It only differs from the galactite, in that it is milder to the taste. (See Galactites.) The ancients used it in inflammations of the eyes, and to dry ulcers.

They also applied it externally in ulcers, and gave it inwardly as a soporific to people who were to suffer pain, supposing it would make them less sensible of it. It is at present very common in Italy, and probably in many other places, but is not known or regarded.

Melitites *Lapis*, a name given by some authors to some of the rounder species of echinitæ, from their resembling an apple in their shape.

MELITO, in *Biography*, an ancient Christian father, who flourished in the second century, was bishop of Sardis. Some moderns have supposed him the same as the angel of the church of Sardis, to whom the epistle in the book of Revelation was directed, but the most judicious critics have abandoned this idea. He travelled into Palestine for the purpose of ascertaining the number of books of the Old Testament, and he is the first Christian writer who has given us a catalogue of those books, which agrees with that of the Jews, excepting that it does not contain the book of Esther. Melito was in the number of those fathers who wrote in defence of the Christian faith, and addressed an apology to the emperor Marcus Antoninus in behalf of the persecuted Christians, of which a fragment is preserved by Eusebius. In this piece he intreats the emperor to examine the accusations which were preferred against the Christians, and to put an end to their persecutions and sufferings, by revoking the edict that he had published against them. He represented to him, "that so far was the Roman empire from having been injured or weakened by Christianity, that it was the more firmly established since the introduction of that religion into it." He boldly stated that the Christian religion had been persecuted only by wicked emperors, such as Nero and Domitian: and that, therefore, they naturally indulged the hope, that from his known clemency and goodness they should receive the same protection which they had enjoyed under the reign of Adrian. The date of this apology is fixed by Eusebius to 170, but Lardner and some others, from internal evidence, give it the date of 175 or 177. Melito was author of various treatises, the titles of which may be seen in the works of Eusebius, but of these only a few fragments remain. From the title of one of those pieces, "Concerning the Revelation of John," critics have inferred that he esteemed the book of Revelation of canonical authority, and to have been written by the apostle John. We have no account of Melito's death, except what is gathered from a letter of Polycrates to Victor, bishop of Rome, which proves it took place before the election of that pontiff, in the year 192. Lardner. Gen. Biog.

Melito, in *Geography*, a small town and bishop's see of Naples, in Calabria Ultra, several miles S. of Monte Leone.

MELITOPOL, a town of Russia, in the province of Tauris, situated on a lake about 12 miles from the sea of Azof. N. lat. 46° 12′. E. long. 35° 10′.

MELITTIS, in *Botany*, from μελιττα, which in the attic dialect is the name of a bee; so that this word is, in fact, equivalent to *Melissa*, and was adopted by Linnæus therefore for the Bastard Balm.—Linn. Gen. 299. Schreb. 395. Willd. Sp. Pl. v. 3. 157. Mart. Mill. Dict. v. 3. Sm.

Fl.

Fl. Brit. 643. Ait. Hort. Kew. ed. 2. v. 3. 421. Juff. 116. Lamarck Dict. v. 4. 80. Illuftr. t. 513.—Clafs and order, *Didynamia Gymnofpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-fhaped, round, ftraight, its mouth two-lipped; *upper lip* longeft, acute; *lower* fhorteft, cloven, acute, its fegments gaping. *Cor.* of one petal, ringent; *tube* much narrower than the calyx; mouth not much wider; *upper lip* erect, roundifh, undivided; *lower* fpreading, three-cleft, obtufe, its middle fegment largeft, flat, undivided, crenate. *Stam.* Filaments four, awl-fhaped, fheltered by the upper lip, the two intermediate ones fhorter than the outer ones; anthers cohering in pairs, forming a crofs, cloven, obtufe. *Pift.* Germen obtufe, four-cleft, hairy; ftyle thread-fhaped, the length and fituation of the ftamens; ftigma cloven, acute. *Peric.* none, except the unchanged calyx. *Seeds* four, in the bottom of the calyx.

Obf. The fegments of the calyx differ in number in the different fpecies.

Eff. Ch. Calyx unequal, much wider than the tube of the corolla. Upper lip of the corolla flat; lower three-lobed, crenate. Anthers forming a crofs.

1. M. *Meliffophyllum*. Reddifh Baftard-Balm. Linn. Sp. Pl. 832. Engl. Bot. t. 577. Jacq. Auftr. t. 26. (Meliffophyllum; Rivin. Monop. Irr. t. 21. f. 2. Meliffa Fuchfii; Camer. Hort. t. 30.)—Calyx three-lobed, nearly fmooth.—Native of rather mountainous woods and thickets in Germany, Switzerland, France, Greece, and the fouth-weft extremity of England, flowering in the beginning of fummer. The *root* is fibrous and perennial. *Stems* herbaceous, erect, fimple, fquare, leafy, hairy, about eighteen inches high. *Leaves* oppofite, ftalked, ovate, ferrated, hairy, full two inches long and one broad; paler and rather polifhed beneath. *Flowers* axillary, about three on each fide, moftly turned one way, on fimple reddifh round ftalks. *Calyx* purplifh, with hairy ribs, ample, three-lobed; the upper lobe or lip longeft, acute, often notched or toothed at each fide; lower lip in two vertical, equal, pointed or notched, fide-lobes. *Corolla* large and handfome, thrice the length of the calyx, externally flefh-coloured; internally whitifh, the lip marked with a divided crimfon fpot, and a few dots on its principal fegment, and more or lefs of a ftain on its two lateral lobes. The whole *herb* has, when frefh, rather an offenfive fmell; when dried it acquires the fcent of new hay, like woodruff, which is alfo the cafe with the next. Some of the old authors miftook this *Melittis*, or the following, for they did not always diftinguifh the two, for the μελισσοφυλλον of Diofcorides; but that is evidently rather our *Meliffa officinalis*, and as far as can be concluded from the fynonym of *Apiaftrum*, the *Meliffophyllum* of Pliny. Haller therefore is to blame in citing the Roman author, to fupport his own preference of this laft-mentioned name, to that adopted by Linnæus, for the genus before us.

2. M. *grandiflora*. Purple and White Baftard-Balm. Engl. Bot. t. 636. (M. Meliffophyllum; Curt. Lond. fafc. 6. t. 39. Mill. Illuftr. t. 52. Meliffophyllum; Rivin. Monop. Irr. t. 21. f. 1. M. adulterinum; Fuchs. Hift. 497. fig. 498, verum.)—Calyx in four equal lobes, nearly fmooth.—Native of woods in Hungary and Switzerland, as well as in Devonfhire and Cornwall, flowering early in the fummer. Linnæus, Haller, and their pupils for the moft part, have confounded this with the foregoing, from which it differs effentially in the *calyx*, whofe lobes are four, all lateral, none vertical, for the moft part entire, though fometimes notched. The *corolla* is larger than the other fpecies, white, with a pale tinge of yellow or cream colour in its upper part, the middle fegment of its lower lip purple with a white margin. The general habit form and fcent of the two plants agree, but this is rather the moft ornamental. Clufius diftinguifhed them in his *Hift. v.* 2. 37, as did after him Johnfon in Ger. em. 690. The figure in Fuchfius marked *Meliffophyllum verum*, is evidently intended for our prefent plant, the calyx being very clearly defined; but his account can only belong to the Garden Balm, *Meliffa officinalis*, as the lemon fcent is particularly noticed. It feems therefore that the cuts of thefe two very diffimilar plants have been tranfpofed by his printer, a miftake hitherto unnoticed. Hence Fuchfius is very erroneoufly quoted by Vaillant, Haller, and others, as making this *Melittis* the true *Meliffa*, or μελισσοφυλλον.

3. M. *japonica*. Japan Baftard-Balm. Thunb. Tr. of Linn. Soc. v. 2. 338. Willd. n. 2. (M. Meliffophyllum, Thunb. Jap. 248.)—Calyx hairy. Leaves alternate, ovate, obtufe, unequally ferrated.—Native, as it is prefumed, of Japan, though Thunberg faw only one plant, cultivated in a pot, in the ifland of Nipon, in his journey towards Jeddo, flowering in May and June. The Japanefe called it *Sjuwo*. *Stem* erect, villous, fimple, a fpan high. *Leaves* alternate, ftalked, ovate, obtufe, unequally and doubly ferrated, villous, fpreading, a finger's length. *Footftalks* the length of the nail. *Flowers* axillary, folitary, each on a hairy ftalk, an inch long. *Calyx* rough with briftles, drooping. *Thunb.*

The *leaves* being alternate, is fo improbable in this genus, that we cannot but fufpect a miftake in that particular, or in the generic characters of the plant. We know nothing of this fpecies but what Thunberg has given above.

Melittis, in *Gardening*, comprehends a plant of the flowery perennial kind, of which the fpecies cultivated is, the baftard balm (M. meliffophyllum).

In this plant there is much honey fecreted, from a gland that encircles the bafe of the germ; it is of courfe a favourite plant with bees.

And there is a variety fmaller in all refpects, with the leaves ovate and heart-fhaped, the flowers not fo large, and ufually of a pale red, but fometimes white, which is a native of Switzerland, and other fimilar fituations.

Method of Culture.—Plants of this fort are capable of being increafed by parting the roots and planting them out early in the autumn, where they are to remain; but the roots fhould not be parted oftener than every third year. When feeds can be procured, they may alfo be raifed by fowing them in the early fpring, where they are to remain. The plants fucceed beft in a loamy foil and eaftern afpect, where they can be had.

They are capable of affording ornament in the borders and other parts of pleafure-grounds and gardens.

MELIUS Inquirendum, in *Law*, a writ which lieth for a fecond inquiry to be made of what lands and tenements a man died feifed, where partiality is fufpected upon the writ called *diem claufit extremum*.

A "melius inquirendum" fhall be awarded out of B.R. where a coroner is guilty of corrupt practices, directed to fpecial commiffioners. 1 Vent. 181.

MELIZZANO, in *Geography*, a town of Naples, in Lavora; 15 miles E. of Capua.

MELKOVATE, a town of Bulgaria; 52 miles S. of Viddin.

MELKSHAM, a confiderable market-town in the hundred of Melkfham and county of Wilts, England; is pleafantly fituated on the river Avon, at the diftance of 23 miles from Bath, and 96 from London. In ancient times it is faid to have been a place of confiderable note by the

the authors of the Magna Britannia, who aſſert that the Conqueror eſtabliſhed a court of royal juriſdiction here Edward I., according to the ſame authority, had likewiſe a foreſt in this neighbourhood, which was joined to that of Chippenham, and committed to the cuſtody of Matthew Fitz-John, who was governor of the caſtle of Devizes. But if thus important in early times it ſeems to have greatly decayed before the age of Leland, as neither he, nor his ſucceſſor Camden, ſo much as mention it, though the former was undoubtedly in this part of the county. Of late years, however, it has again riſen to ſome degree of conſequence by the influence of trade. For a conſiderable period Melkſham has been celebrated for its manufacture of ſuperfine cloths and caſſimere. The buildings of this town are in general conſtructed of freeſtone, poſſeſſing, individually, an appearance of much neatneſs, but the ſtreets are irregular and narrow. The church, of which the living is a vicarage in the gift of the dean and chapter of Saliſbury, is a ſpacious edifice, with a handſome tower in the centre. Here are likewiſe meeting-houſes for diſſenters of different denominations, particularly Independents and Baptiſts. Methodiſts are leſs numerous than in moſt other towns of the ſame extent in England, though they have increaſed conſiderably of late years. According to the parliamentary returns of 1801, the number of inhabitants in the whole pariſh was eſtimated at 4030 perſons, 1864 males, and 2166 females, of whom 1299 were engaged in trade, and 370 in agriculture. The proportion of poor is very great, owing to the manufactories which have again begun to decline, and will probably ſoon leave the town entirely, as has already taken place with regard to Corſham. Since the introduction of the new proceſs in the cloth manufacture, Melkſham has loſt the advantages it was formerly ſuppoſed to poſſeſs in reſpect of ſituation on the banks of the Avon. The petty ſeſſions for Melkſham and Tinehead diviſion are held here. The market is on every alternate Monday. A branch of the Wilts and Berkſhire canal comes cloſe up to the town, and communicates with Bath and Briſtol. About two miles weſt of Melkſham is Shaw-hill-houſe, the ſeat of R. Heathcote, eſq. Magna Britannia, Wiltſhire. Britton's Beauties of Wiltſhire.

MELL Islands, a cluſter of ſmall iſlands, near the W. coaſt of Scotland. N. lat. 58° 15′. W. long. 4° 57′.

MELLABA, a town of Africa, in the country of Barca. N. lat. 31° 5′. E. long. 23° 44′.

MELLARIA, in *Ancient Geography*, *Fuentes Ovejuna*, a town of Hiſpania, in Bœtica, at the foot of the mountains, and S.W. of Siſapa; which was a conſiderable place, and is mentioned in the Itinerary of Antonine.—Alſo, a town of Hiſpania, in Bœtica (now *Tarifa*), ſituated towards the ſouth on a ſtrait, famous for its ſalt-works and for its commerce in ſalted proviſions. According to the Itinerary of Antonine, it was 12 miles towards the W. from Portus Albus.

MELLATS, in *Chemiſtry*, are combinations of an acid called the mellitic with certain baſes. See Mellitic *Acid*.

MELLE, in *Geography*, a town of France, and principal place of a diſtrict in the department of the Two Sevres; 13 miles S.E. of Niort. The place contains 1741, and the canton 7782 inhabitants, on a territory of 165 kiliometres, in 13 communes. N. lat. 46° 13′. W. long. 0° 4′. —Alſo, a town of Weſtphalia, in the biſhopric of Oſnabruck; 11 miles S.E. of Vorden.

MELLEGETTA, Melegetta, or *Milleguetta*, in *Botany*, the African name, if we miſtake not, of the Grains of Paradiſe, *Amomum Grana Paradiſi* of Linnæus; see Amomum, ſp. 15. See alſo Grain-*Coaſt*, where this word is ſpelt *Malaguetta*, and ſuppoſed to be of Portugueſe origin. It is likewiſe the Spaniſh name of the ſame drug, and, wherever it may have originated, is now in common uſe amongſt the black natives of Sierra Leone. From thence we obtained, many years ago, by the kindneſs of Dr. Adam Afzelius, ſpecimens of theſe grains in their native huſk or capſule, a thing heretofore unknown among collectors of *Materia Medica* in England. We received alſo, at the ſame time, ſpecimens of the plant, which is a genuine *Amomum*, according to Mr. Roſcoe's able elucidation of the Linnæan order of *Scitamineæ*, ſee Tr. of Linn. Soc. v. 8. 351. t. 20. f. 11; and is now growing, in many of the Engliſh ſtoves, from ſeeds brought over by Dr. Afzelius; but we have never heard of its flowering. The new edition of Ait. Hort. Kew. does not contain this ſpecies, but it is admitted into the catalogue of the Cambridge garden by Mr. Donn, we believe with perfect propriety. As no authentic characters or deſcriptions of this plant have appeared, and its ſynonyms are altogether confuſed, even in the beſt writers, we ſhall attempt to clear up the whole of its hiſtory.

Amomum *Grana Paradiſi*, Grains of Paradiſe. (True Mellegetta Pepper. *Afzelius*.) Linn. Sp. Pl. 2. Berg. Mat. Med. v. 1. 3. (A. n. 3; Linn. Mat. Med. 2, with an erroneous character. Grana Paradiſi officin; Dale Pharmac. 277; Bauh. Pin. 413; both with many wrong ſynonyms. Melligetta; Cord. Hiſt. 195. Melegueta; Bauh. Prod. 158. Lobel. Adverſ. 445.)—Stalk ſimple. Bracteas numerous, cloſely imbricated. Leaves crowded, ovato-lanceolate, pointed. Capſule oblong, bluntly triangular, minutely hiſpid. Seeds roundiſh.—Native of Guinea, about Sierra Leone, from whence the ſeeds were brought very ſoon after the diſcovery of that country by European navigators. The *root* is perennial, woody, creeping horizontally. *Stems* erect, ſimple, ſlender, three feet high, leafy, but deſtitute of flowers. *Leaves* numerous, crowded, two-ranked, alternate, a ſpan long and an inch broad, lanceolate, or ſlightly ovate, with a long taper point, entire, ſmooth, ſingle-ribbed, ſtriated with innumerable oblique veins. Their flavour is ſlightly aromatic, after having been dried twenty years. *Footſtalks* ſheathing, linear, very long, ſmooth, ſtriated. *Flower-ſtalks* radical, ſolitary, an inch or two in length, aſcending, clothed with numerous, cloſe, ſheathing *bracteas*, all abrupt, ribbed, ſomewhat hairy and fringed; the lower ones very ſhort; the upper gradually much larger. Of the parts of the *flower* nothing can be made out from our ſpecimens. *Capſule* an inch and half long, half an inch in diameter, oblong, bluntly triangular, ſcarcely ovate, beaked, of a dark reddiſh-brown, ribbed, coriaceous, rough with minute deciduous briſtly hairs. When broken it is very powerfully aromatic, even after being kept twenty years, with a peculiar pepper-like flavour, rather too ſtrong to be agreeable. *Seeds* numerous, enveloped in membranes formed of the dried pulp, roundiſh or ſomewhat angular, of a ſhining golden brown, minutely rough or granulated, extremely aromatic, hot, and acrid.

Of this plant or its capſule we have in vain ſought for a figure in any book within our reach. The old authors confounded with it the *Cardamomum majus*, of which a figure may be found in Camerarius's Epitome 11. f. 1. Tabern. Kreuterb. 1319. Matth. Valgr. v. 1. 25. Ger. em. 1542, the largeſt kind. Bauh. Hiſt. v. 2. 204. This is *Amomum anguſtifolium* of Sonnerat's Voyage aux Indes, v. 2. 242. t. 137, found in marſhy ground in Madagaſcar. The habit of this ſpecies is not unlike what we have deſcribed; but the *capſule*, (of which old authors miſtake the baſe for the ſummit, and therefore compare it to a fig,) is very different, being

being ovate, flattened at one side, striated, but smooth, nearly twice the size of the above. *Seeds* larger than the former, but otherwise not very unlike in appearance, though totally different in their flavour, which much resembles that of the small East Indian Cardamom, and has none of that vehemently hot acrid taste, for which the Grains of Paradise are remarkable.

Gærtner has mistaken for the Mellegetta Pepper another very different species of *Amomum*, for which genus he perversely retains the name *Zingiber*. This is figured in his t. 12, by the name of *Z. Melegueta*, and is remarkable for the large and copious bracteas, each two inches long, encompassing the capsule. The latter is nearly as long, ovate, with a corrugated beak. Seeds ovate or nearly globular, partly angular, smooth and polished, lead-coloured, livid, or glaucous, with a strong umbilicated scar at their base, surrounded with a whitish rather tumid margin. Professor Afzelius has favoured us with some seeds which answer very well to this description, except in being twice as large as Gærtner represents them. But this is not an unfrequent error with him. Of the capsule, or plant producing these seeds, we have no information.

Another species, nearly akin to this of Gærtner, (and which we should almost have taken for his plant, were it not for the seeds just mentioned, considered as such by our friend Afzelius,) is described in Clusius, (*Exot.* 38. *fig.* 14.) of which we have one capsule, with seeds. The author describes this as bearing four capsules together at the top of the stalk, encompassed with *short* bracteas at the base, not long ones as in Gærtner. The capsules are two inches in length, ovate with a long beak, slightly triangular, cartilaginous rather than leathery, striated, smooth, reddish-brown. Seeds ovate inclining to cylindrical, dark brown, exquisitely smooth and shining, with a light brown corrugated and notched margin surrounding the scar. They are but slightly aromatic. Clusius seems to have received from Madagascar the true *Cardamomum majus*, *Amomum angustifolium* of Sonnerat mentioned above, which he rightly distinguishes from the Mellegetta Pepper, and seems to imply that it is also distinct from his fig. 14, of which there can be no doubt.

By the above remarks it appears that the species of this genus are very imperfectly known. We have, besides, specimens of some that are not at all described. It is highly desirable that botanical travellers should pay particular attention to this tribe, the seeds of several of which are important articles of commerce, and not useless in medicine. The botanical history of none of the Cardamoms was properly known to Linnæus, and that of the *Cardamomum medium*, *Zingiber Ensal* of Gærtner, is still entirely in the dark. By the inflorescence we presume it of Dr. Maton's genus *Elettaria*, Tr. of Linn. Soc. v. 10. 254. S.

MELLI, or Lamlem, in *Geography*, a country of Africa, bounded on the N. by Cashna, on the E. by Wangara, on the S. by Guinea, from which it is separated by mountains, and on the W. by Gago; 500 miles in length from E. to W., and from 150 to 200 in breadth. N. lat. 11° 30′ to 15°. E. long. 5° 30′ to 14° 50′.

MELLID, a town of Spain, in Gallicia; 20 miles E. of Compostella.

MELLIFAVIUM, (from *mel* and *favus*, a honey-comb,) in *Surgery*. See Meliceris.

MELLITE; *Honig-stein*, Wern.; *Honey-stone*, Jameson; *Mellite*, Haüy, Broch. Brongn.; *Mellilite*, Kirw.

This mineral, which, by most mineralogists, is classed with the inflammable substances, was mistaken, by Born and other writers, for a crystallized variety of amber, till Werner and Laumont, and principally Klaproth, determined its true nature, which is totally different from that of any other mineral substance we are acquainted with.

Its colour is honey-yellow, of more or less purity and intensity, passing into wax and sometimes into straw and greyish-yellow.

It is seldom found massive and in detached grains; generally crystallized.

The primitive form of the crystals is an octohedron with common base perfectly square; the inclination of each face of the four-sided pyramid, on its corresponding face in the other pyramid, is, according to Haüy, $= 93° 22'$. This primitive crystal (Mellite *primitif*, Haüy, pl. 62. f. 12.) occurs more frequently than the following modifications.

1. The primitive octohedron having all the solid angles of the base replaced by quadrilateral planes, which, when they meet, form a rhomboidal dodecahedron, which is, however, different from the garnet dodecahedron in the measurement of its angles. (Mellite *dodécaèdre*, Haüy, ib. fig. 14.)

2. The primitive octohedron, with the solid angles of the base as well as those of the summit of the pyramids, each replaced by a quadrilateral plane, the surface of which is sometimes more or less convex or curvilinear. (Mellite *épointé*, Haüy, ib. fig. 13.)

The crystals, which are small and very small, are generally singly dispersed, sometimes grouped together; their surfaces are smooth and shining, seldom rough, and, as it were, corroded.

Internally it is splendent; lustre intermediate between vitreous and resinous.

Fracture perfectly conchoidal; the fragments are indeterminately angular, and pretty sharp-edged.

It is seldom found perfectly transparent; oftener translucent and opaque, and possesses a very distinct double refraction.

It is soft; more so than amber. Brittle. Easily frangible, and yields a yellowish-grey powder. Specif. gravity 1.550, Klapr., 1.5858, Haüy, 1.666 Abich. The purer crystals become slightly electric by friction.

Exposed to the flame of a candle, or on a burning coal, it first becomes opaque, and white spotted with black, which soon gives way to a pure white. No smoke, flame, or odour are perceived during this process. Projected on melted nitre no real detonation takes place, but only a slight scintillation; and the earthy part remains mixed with the nitre.

It is entirely soluble in nitric acid without heat, and the fragments remain translucid; in muriatic acid, on the other hand, the fragments become more or less opaque.

Abich and Lampadius have given analyses of mellite, which are completely superseded by those performed by Klaproth, according to which this substance is composed of

Alumine	16
Mellitic acid	46
Water of crystallization	38
	100 Kl. Beitr. ii. p. 134.

This analysis has been confirmed by Vauquelin in Ann. de Ch. vol. xxxvi. p. 203.

This substance has been hitherto found only at Artern, in Thuringia, on a bed of bituminous wood and brown coal, accompanied by small crystals of native sulphur, which by the inattentive observer might be easily mistaken for the straw-yellow variety of mellite. Langenbogen in the Saal circle has been mentioned as another locality of this mineral, as likewise Switzerland, where it is said to have been found with flaggy asphaltum.

MELLITIC Acid, in *Chemistry*, is a product obtained

tained from the mineral called mellite, or honey-stone. It was discovered by Klaproth in the year 1799 (Beiträge, tom. iii. p. 114.); and the existence of it was shortly afterwards confirmed by the researches of Vauquelin (Annales de Chimie, tom. xxxvi. p. 203.) To procure this acid, it is merely necessary to boil the mellite, reduced to powder, in about seventy times its weight of water. The alumine with which it is combined in its native state, is by this process precipitated, and after filtering the solution, and evaporating it to a sufficient degree, the acid appears in a state of tolerable purity. It may be still contaminated with the presence of a little earthy matter; but, by exposing it to the action of alcohol, this will be detached, and it may then be obtained crystallized under the form of needles, or short prisms. In Vauquelin's analysis, the substance under enquiry was procured by adding the pulverized mellite to a solution of carbonat of potash; carbonic acid being evolved, and the mellitic acid uniting to the alkali. Nitric acid was afterwards presented to take up the alkaline base, and the mellitic acid separated, in the course of a few hours, in short prismatic crystals. Thus crystallized, this acid has a brownish-yellow tinge; its taste is slightly sour, accompanied with bitterness; and it is but sparingly soluble in water. Exposed to heat, it is easily decomposed, and emits a dense smoke which has no odour. With the alkalies, earths, and metallic oxyds, it enters into combination, and forms a class of salts, which, in conformity with the principles of the present chemical nomenclature, are denominated *mellats*. The properties of these, however, have been but very imperfectly examined. Mellat of potash crystallizes in prisms, which apparently differ from those of the acid in being longer. The form of mellat of soda is a cube, or three-sided table. The union of mellitic acid with ammonia yields fine transparent six-sided prisms, which become opaque on exposure to the air. Barytes, strontian, and lime, form insoluble compounds; as also does alumine. Solutions of silver, lead, and mercury afford each a white precipitate; but from iron a yellow compound is deposited. This acid, in many of its properties, bears a very near resemblance to the oxalic; but, in others, it exhibits a sufficient difference to forbid our considering them identical. The products it affords when decomposed by heat, are pretty much like those yielded by the vegetable acids. This species of analysis, however, has been, hitherto, so rude and unsatisfactory, that no very accurate comparison can be grounded upon the evidence which it supplies. The acute researches of M. M. Gay Lussac and Thenard have, in a very eminent degree, removed this defect; and we may shortly hope, aided by the light which their genius has diffused over these subjects, to find vegetable chemistry equally demonstrative and certain in its operations with the most accurate branches of experimental science. See Recherches Physico-Chimiques par Gay Lussac et Thenard, tom. ii.

MELLO-MESQUITELA, in *Geography*, a town of Portugal, in the province of Beira; 12 miles W. of Guarda.

MELLOON, or MELONE, a town of the Birman empire, on the W. side of the Ava, rich in temples, but in no other respect distinguished. N. lat. 20° 10′. E. long. 96° 9′.

MELLOOR, a town of Hindoostan, in Madura; 12 miles N.E. of Madura.

MELLOUNOSH, a town of Africa, on the E. coast of Tunis; 20 miles S.E. of Jemme.

MELLYPOUR, a town of Hindoostan, in Bahar; 38 miles W.S.W. of Boglipour.

MELMOTH, WILLIAM, in *Biography*, an eminent and learned pleader at the bar, and member of Lincoln's-Inn, was born in 1666. He became a bencher of that honourable society, and, in conjunction with Mr. Peere Williams, published Vernon's "Reports," under an order of the court of Chancery. It appears that he had an intention of printing his own Reports, and even advertised them as actually preparing for the press. They have not, however, made their appearance. But the work by which he is best known, and for which he will be very long remembered, is entitled "The Great Importance of a Religious Life." This little tract has gone through many editions; more than 40,000 copies were circulated in the course of twenty years, independently of other large impressions that have been taken off, as well for sale as for charitable purposes: and while this article was writing, several copies of a new edition of this valuable tract came into the hands of the writer, from a friend who has undertaken the office of editor, with the view of circulating it among persons into whose hands it would, without his exertions, scarcely have come: and with the hope, that by omitting certain expressions in controverted theology, "the work might recommend itself to a numerous and additional body of rational disciples of our common master." It is a singular circumstance, that the author of this treatise, so much read and highly applauded, should not have been known till the fact was revealed by his son. It was commonly attributed to the first earl of Egmont, to whom it had been given by Mr. Walpole in his Catalogue. Mr. Melmoth died on the 6th of April 1743, and was buried under the cloister of Lincoln's-Inn chapel. His character has been drawn by his son, the subject of the next article, in the following words: "The author's life was one uniform exemplar of those precepts which, with so generous a zeal, and such an elegant and affecting simplicity of style, he endeavours to recommend to general practice. He possessed by temper every moral virtue; by religion every Christian grace. He had a humanity that melted at every distress; a charity which not only thought no evil, but suspected none. He exercised his profession with a skill and integrity which nothing could equal, but the disinterested motive that animated his labours, or the amiable modesty which accompanied all his virtues. He employed his industry, not to gratify his own desires; no man indulged himself less: not to accumulate useless wealth, no man more disdained so unworthy a pursuit: it was for the decent advancement of his family, for the generous assistance of his friends, for the ready relief of the indigent. How often did he exert his distinguished abilities, yet refused the reward of them, in defence of the widow, the fatherless, and him that had none to help him! In a word, few people have ever passed a more useful, not one a more blameless life; and his whole time was employed in doing good, or in meditating it." See preface to "The Great Importance of a Religious Life, &c." 1812. Also "Memoirs of a late eminent Advocate, &c." By William Melmoth, esq. 1796.

MELMOTH, WILLIAM, son of the above, was born in 1710, and first appeared as a writer about the year 1742, in a volume of "Letters" under the name of Fitzosborne, which have been much admired for the elegance of their language, and their just and liberal remarks on various topics, moral and literary. In 1747 he published "A Translation of the Letters of Pliny," in 2 vols. 8vo., which was regarded as one of the best versions of a Latin author that had appeared in our language. In 1753, he gave a translation of the "Letters of Cicero to several of his Friends, with Remarks," in 3 vols. He had previously to this, written an anſwer to Mr. Bryant's attack, in his Treatiſe on the Truth of the Chriſtian Religion, on his remarks on Trajan's Perſecution of the Chriſtians in Bithynia, which made a note to his tranſlation of Pliny's Letters. He was the tranſlator likewiſe of Cicero's treatiſes "De Amicitia" and "De Senectute," which were publiſhed in 1773 and 1777. Theſe he enriched with remarks, literary and philoſophical, which added much to their value. In the former he refuted lord Shaftſbury, who had imputed it as a defect to Chriſtianity, that it gave no precepts in favour of friendſhip, and Soame Jenyns, who had repreſented that very omiſſion as a proof of its divine origin. The concluding work of Mr. Melmoth was a tribute of filial affection, in the Memoirs of his father, of which we have already made uſe. After a long and reſpectable life paſſed in literary purſuits, and the practice of private virtue, Mr. Melmoth died at Bath, March 15, 1799, at the age of 89. He had been twice married; firſt to the daughter of the celebrated Dr. King, principal of St. Mary's-hall, Oxford, and ſecondly to Mrs. Ogle. "The author of 'The Purſuits of Literature,' ſays Mr. Melmoth, "is a happy example of the mild influence of learning on a cultivated mind; I mean that learning which is declared to be the aliment of youth, and the delight and conſolation of declining years. Who would not envy this fortunate old man, his moſt finiſhed tranſlation and comment on Tully's Cato? Or rather, who would not rejoice in the refined and mellowed pleaſure of ſo accompliſhed a gentleman, and ſo liberal a ſcholar?" Gent. Mag. Preface to Fitzoſborne's Letters, 1805.

MELNERSENS, in *Geography*, a town of Weſtphalia, in the principality of Luneburg-Zelle; 16 miles S.E. of Zelle.

MELNIK, a town of Bohemia, in the circle of Boleſlaw, at the conflux of the rivers Elbe and Moldau; 18 miles N. of Prague. N. lat. 50° 20'. E. long. 14° 40'.

MELO, in *Botany*, from μηλον, *an apple*, the Melon. See CUCUMIS.

MELOCACTUS, ſo called from *Melo*, a Melon, and *Cactus*, the Torch-thiſtle, becauſe the whole plant reſembles a large green deeply-furrowed melon. See CACTUS.

MELOCHIA, a name adopted by Dillenius from Proſper Alpinus. Sonnini ſays it is the Arabic appellation of *Corchorus olitorius*, a plant agreeing in many particulars of habit and properties with the genus in queſtion. Linn. Gen. 348. Schreb. 454. Willd. Sp. Pl. v. 3. 600. Mart. Mill. Dict. v. 3. Juſſ. 274. Cavan. Diſſ. 318. Lamarck Dict. v. 4. 81. Illuſtr. t. 571. Gærtn. t. 113.—Claſs and order, *Monadelphia Pentandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cut half-way down into five, half-ovate, acute, permanent ſegments, and ſometimes accompanied by an external unilateral calyx of three leaves. *Cor.* Petals five, inverſely heart-ſhaped, large and ſpreading. *Stam.* Filaments five, awl-ſhaped, united at the baſe into a little cup embracing the germen; anthers ſimple. *Piſt.* Germen ſuperior, roundiſh; ſtyles five, awl-ſhaped, erect, the length of the ſtamens, permanent; ſtigmas ſimple. *Peric.* Capſule roundiſh, or five-ſided, of five cells and five acute valves, with double partitions contrary to the valves. *Seeds* either ſolitary or in pairs, roundiſh on one ſide, angular from compreſſion at the other.

Eſſ. Ch. Calyx ſingle or double. Petals five, ſpreading. Filaments awl-ſhaped. Styles five. Capſule of five cells. Seeds one or two in each cell.

A tropical, and principally Weſt Indian genus of plants, for the moſt part ſhrubby, and agreeing with *Sida*, more than with any other of the ſame natural order, in habit and appearance. The 14th edition of Syſt. Veg. enumerates ſeven ſpecies; Willdenow has fourteen. The *leaves* in all are ſtalked, ſimple, ſcarcely lobed, unequally crenate or ſerrated, and of courſe alternate. *Flowers* various in ſize, ſituation, and colour. The following examples may ſuffice.

M. *pyramidata*. Linn. Sp. Pl. 943. Jacq. Hort. Vind. v. 1. 11. t. 30. Cavan. Diſſ. 319. t. 172. f. 1.—Flowers in lateral umbels. Capſule pyramidal, with five ſharp-pointed angles. Leaves naked.—Native of Braſil and the Caribbee iſlands. It has long been known in the ſtoves of this country, but is kept rather as a curioſity than an ornament. The *ſtem* and *branches* are round, ſtraight and wand-like. *Leaves* ovate, pointed, ſerrated, two or three inches long and one broad, ſmooth, with one rib, and many ſtraight, parallel, oblique veins. *Flowers* ſmall, purple, four or five together, in lateral hairy umbels.

M. *concatenata*. Linn. Sp. Pl. 944. Cavan. Diſſ. 322. t. 175. f. 2. (Althæa indica, floſculis parvis, &c.; Pluk. Phyt. t. 9. f. 5.)—Spikes terminal, crowded. Capſules globoſe. Leaves ſerrated, naked.—Native of both Indies. We have not met with it in any garden. The *inflorescence*, and very ſmall *flowers*, diſtinguiſh this from the foregoing; and the globular capſules, about the ſize of peas, encompaſſed with the long linear ſegments of the *calyx*, and diſpoſed in *ſpikes*, like beads, are peculiar.

M. *odorata*. Linn. Suppl. 302. Forſt. Prod. 47. Cavan. Diſſ. 320. t. 173. f. 2.—Leaves ovate, ſomewhat heart-ſhaped, doubly ſerrated, naked. Corymbs axillary, many-flowered, downy, on long ſtalks.—Gathered by Forſter in the iſlands of Tanna and Amſterdam. A very fine ſpecies, with broad ovate *leaves*, three or four inches long, doubly and coarſely ſerrated, naked but roughiſh to the touch. The very abundant large and handſome *flowers*, which we preſume are fragrant, grow on long, corymboſe, finely downy, axillary *ſtalks*. *Calyx* downy, globoſe, with long ſharp ſegments. *Petals* much longer than the calyx, of what colour we know not.

M. *lupulina*. Swartz. Ind. Occ. v. 2. 1141.—Cluſters compound, crowded, axillary, ſomewhat umbellate, hairy. Leaves ovate or heart-ſhaped, doubly ſerrated, ſoft and hairy beneath.—Native of Jamaica. Communicated to the younger Linnæus by ſir Joſeph Banks. The ſhape of the *leaves* is not unlike the laſt, but their under ſide is clothed with minute hairs, very ſoft to the touch. The permanent ſcarioſe *calyx* has a tawny hue and ſomewhat of the aſpect of hops. *Corolla* ſmall, white.

M. *corchorifolia*. Linn. Sp. Pl. 944. Dill. Elth. t. 176. f. 217.—Flowers in axillary ſeſſile hairy heads. Leaves ovate, obſcurely lobed, crenate, ſmooth.—Native of the Eaſt Indies. The *leaves* are about two inches long, very ſmooth. *Flowers* ſmall, pale fleſh-coloured, in ſmall axillary heads.

MELODIA, Lat. and Ital., *Melodie*, Fr., μελωδια, Gr., from μελος and ωδη, *continuata ſonorum connexio*; *Melody*, Eng.

To deſcribe all the rules and prohibitions in framing melodies, would require a code of laws equal to an art of poetry.

Dr. Pepuſch (Treatiſe on Harmony) gives a very ſhort, but intelligible definition of melody; which, he ſays, "is the progreſſion of ſound proceeding from one note to another ſucceſſively in a ſingle part."

Rouſſeau is eloquent on the ſubject. Melody he defines, "the ſucceſſion of ſounds according to the laws of rhythm and modulation, ſo as to form muſical phraſes agreeable to the

the ear; vocal melody is called *chant* by the French, inſtrumental is called *ſymphonie*."

The Italians called melody *cantilena*; by the Engliſh it is termed air, tune, principal or treble part.

A ſeries of ſounds only becomes melody by being in ſome ſpeciſic time, or meaſure, that is, by being arranged in regular proportions of time, called *bars*; which, however divided and ſubdivided into notes of different value, muſt be performed iſochronally, that is, in equal time, and theſe bars have their laws likewiſe, and are governed by *accents*. See ACCENT and BAR.

Though melody is ſo neceſſary in the treble part of a compoſition, it is not neceſſary in the baſe, at leaſt of the ſame kind. A polyphonic compoſition is admired by maſters when all the parts *ſing*, that is, when each part has a ſeries of notes that may be called melody; unleſs in fugues and imitations, it is not neceſſary that the inferior part ſhould move in the ſame kind of notes as the principal. For as only thirds and ſixths can move together in a regular aſcent or deſcent in the ſame kind of notes diatonically, they ſoon tire, and manifeſt a want of reſources in the compoſer. And though melody is admired and expected in the ſeveral parts, it is beſt when of a different character from the principal part.

It is in the following periods that the eloquence, feeling, refined taſte, and enlarged views of Rouſſeau appear in this article.

"Melody," he ſays, "is founded on two different principles: conſidered in the relations which the ſounds of a key bear to each other, it has its principle in harmony, as it is an harmonical analyſis, which gives the degrees of the gammut, the chords of the key, and the laws of modulation, the only elements of melody. Upon this principle all the force of melody is confined to the flattering the ear with agreeable ſounds, as the eye is flattered by an agreeable change of colours, without their repreſenting by their mixture any particular object or deſign. But conſidered as an art of imitation, by which we can awaken different images in the mind, move the heart with different ſentiments, excite and calm the paſſions, operate, in ſhort, moral effects beyond the immediate empire of the ſenſes, we muſt ſeek another principle; for no ſuch effects as theſe can be derived from harmony.

"What then is the ſecond principle? It is in nature as well as the firſt; but it can only be diſcovered by more ſubtle and penetrating obſervation, to which nature only gives birth, and which cannot be taught. It is inſtinctive, and often unknown to the poſſeſſor. This principle is the ſame as that which varies the tone of voice in ſpeech, according to what we ſay, and what we feel in ſaying it. It is the accent of languages which determines the melody of every country; it is the accent which ſpeaks in ſinging; and we ſpeak with more or leſs energy, as the language has more or leſs accent. The language in which the accent is moſt marked, produces a melody the moſt lively and impaſſioned; and that which has little or no accent, can only ſuggeſt a languid and cold melody, without character and without expreſſion. Theſe are the true principles. When we quit them, and ſpeak of the power of muſic over the human heart, we know not what we talk about. If muſic only paints by the power of melody, and derives from melody all its force, it follows that all muſic which does not *ſing*, however harmonious it may be, is not an imitative muſic; for as it can neither move the affections nor paint with its fine chords, it ſoon tires the ear and leaves the heart cold. It follows, then, that in ſpite of the multiplicity of parts which harmony can furniſh, and which is ſo often abuſed, as ſoon as two melodies are heard at once, they mutually enfeeble and efface each other, however excellent they may be in themſelves."

This is the language which the Chineſe, and every people not accuſtomed to harmony, talk. See CHINESE *Muſic*.

Rouſſeau is a champion for melody, and M. Laborde for harmony; but we think now, as we did forty years ago, that melody and harmony are as imperfect when ſeparate, as an animal formed by nature with two legs or two arms, is with one. In muſic, melody and harmony have each diſtinct and peculiar beauties; but after being heard together, nothing can compenſate for their ſeparation. Melody ſhould be poliſhed, and harmony purified; but it was one of the paradoxes of the ingenious Jean Jacques, in aſſerting "that harmony was an imperfection, a Gothic and barbarous invention; only wanted by the groſs and obtuſe organs of northern regions."

Rhythm is as neceſſary to melody, as that the ſounds ſhould follow each other in a manner agreeable to the ear. Sounds of the ſame length can form no intereſting melody; they muſt be broken into notes of different duration, muſt be phraſed, and have ſome ſenſe given them, as well as words in literature and grammar.

MELODIEUX, *Fr.* Melodious. This epithet is ſeldom applied with accuracy. A ſweet-toned voice in ſpeech or ſong may be called *melodious*; but to ſay that an air or tune, or a piece of muſic is melodious, is a pleonaſm that borders on vulgarity: as theſe words themſelves imply melody; therefore to ſay that an air or tune is melodious, is ſaying that melody is melodious.

MELODINUS, in *Botany*, is one of Forſter's genera, derived from *μηλον, an apple*, and *δινεω, to entwine*, becauſe the plant bears globular fruit reſembling apples, and its ſtem is twiſted or ſcandent.—Forſt. Nov. Gen. 19. Linn. Suppl. 23. Schreb. 165. Willd. Sp. Pl. v. 1. 1274. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 74. Juſſ. 148. Lamarck Illuſtr. t. 179.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, permanent, of one leaf, cloven into five, ovate ſegments, folding over each other at the margin. *Cor.* of one petal, ſalver-ſhaped; tube cylindrical, thrice as long as the calyx; limb flat, cloven into five, ſickle-ſhaped, crenulated ſegments, twiſted to the right, ſhorter than the tube. Nectary in the mouth of the tube, ſtellated, compoſed of five, cloven, lacerated ſegments. *Stam.* Filaments five, awl-ſhaped, very ſhort, in the middle of the tube; anthers ovate. *Piſt.* Germen ſuperior, globoſe; ſtyle round, the length of the calyx, diviſible into two parts; ſtigma conical, acute. *Peric.* Berry fleſhy, globoſe, with a fleſhy partition. *Seeds* numerous, ovate, or roundiſh, rather compreſſed, imbedded in pulp.

Eſſ. Ch. Corolla contorted, its mouth crowned with five cloven jagged valves. Berry globoſe, of two cells, with many ſeeds.

1. M. *ſcandens*. Climbing Melodinus. Linn. Suppl. 167. Forſt. Prod. 20.—Gathered in New Caledonia by Forſter, who ſent it to Kew Garden in 1775. It is kept in the ſtove, but does not appear to have flowered. The *ſtem* is ſhrubby, climbing, with round, ſmooth, leafy branches. *Leaves* oppoſite, ovate-oblong, with a blunt point, entire, three or four inches long, thick-edged, ſmooth and ſhining, with one rib, and numerous, fine, reticulated veins; paler beneath. *Footſtalks* very ſhort and thick. *Stipulas* none. *Flowers* terminal, numerous, in a denſe downy panicle, with oppoſite ſtalks, and ſmall, ovate bracteas. The *corolla* is externally downy, about half an inch long. *Fruit* the

the ſize of a ſmall orange. The habit of this plant, and form of the flowers, are much like *Rauwolfia*, but the numerous ſeeds afford a ſufficient mark of diſtinction.

MELODORUM, ſo named by Loureiro, from *mel*, *honey*, and *odorum*, *fragrant*, on account of the remarkable ſweetneſs and fragrance of the fruit; as he himſelf informs us.—Loureir. Cochinch. 351.—Claſs and order, *Polyandria Polygynia*. Nat. Ord. *Coadunatæ*, Linn. *Anonæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of three ſhort, acute, ſpreading, permanent leaves. *Cor.* Petals ſix, triangular, nearly equilateral, fleſhy, inflexed and cloſed, in a double row, concealing the organs of impregnation. *Stam.* Filaments none; anthers numerous, oblong, club-ſhaped, affixed to a ſlightly convex receptacle. *Piſt.* Germens ten, oblong, preſſed together by the ſurrounding anthers; ſtyles none; ſtigmas forming a circle, very ſhort. *Peric.* Berries ten, ovate-oblong, rather cylindrical, rough, of one cell, with many ſeeds. *Seeds* compreſſed, imbedded in pulp.

Eſſ. Ch. Calyx of three leaves. Petals ſix, triangular, equilateral, cloſed. Berries numerous, oblong, many-ſeeded.

1. M. *fruticoſum*. Cây Bo gie of the Cochinchineſe.—Leaves lanceolate, ſmooth. Stem ſhrubby.—Native of buſhy places in Cochinchina. *Stem* four feet high, erect, with ſpreading *branches*. *Leaves* alternate, lanceolate, entire, ſmooth, fragrant. *Flowers* ſcattered, ſolitary, yellowiſh-brown. *Berries* of the ſame colour, an inch and a half long, with many ſeeds, and a very ſmall quantity of highly delicious pulp. A decoction of the *leaves* is uſed for removing obſtructions.

2. M. *arboreum*. Cây Nhaoc of the ſame people.—Leaves oblong, downy. Stem arboreous.—Native of woods in Cochinchina. A large *tree*, with aſcending *branches*. *Leaves* alternate, ſtalked, ovate-oblong, pointed, entire; downy beneath. *Flowers* ſcattered, ſolitary, whitiſh-green, fleſhy, downy, on very ſhort ſtalks. *Berries* numerous from each flower, not eatable. The timber is uſed for building.

Theſe plants appear, by the above deſcriptions, to be very nearly allied to the genus *Uvaria*, to which indeed we ſhould, without much heſitation, refer them. Willdenow has omitted them.

MELO-DRAMA, Lat., a drama written for muſic. In 1772, when a few perſons in France began to perceive that it was poſſible for operas to be ſet to better muſic than that of Lulli and Rameau, an anonymous treatiſe was publiſhed at Paris, under the title of "Traité du Melo-drame, ou Reflexion ſur la Muſique dramatique," 8vo.

In 1765, a ſmall tract was publiſhed by the chevalier de Chaſtellux, "On the Union of Poetry and Muſic;" and in 1772, the anonymous "Treatiſe on Muſical Drama." The former had a correſpondence with Metaſtaſio on the ſubject of his book. The poet's anſwers to his letters are preſerved in late editions of his works, and tranſlations inſerted in the memoirs of his life and writings publiſhed in 1796. In the tract of M. de Chaſtellux, he gives in his parallel between muſic and poetry, the *pas* to the former. In the treatiſe on the melo-drama, the preference is decidedly given to poetry; and muſic degraded into his menial ſervant, with no better employment than that of rendering the voice of declamation more audible than that of common ſpeech.

Theſe two writers were the precurſors of the Gluckiſts and Piccinists at Paris. And the diſpute is reduced to this ſimple queſtion; Which, in an opera or muſical drama, is to be the tyrant, and which the ſlave? Metaſtaſio long ſince with reaſon and good taſte determined in his dramas that no tyranny or ſlavery ſhould ſubſiſt; but that the two ſiſters ſhould mutually aſſiſt each other. He gave all the buſineſs of the fable to *recitative*, or muſical declamation, and the embelliſhing ſentiment to the *airs* in a recapitulation of the dialogue at the end of each ſcene.

Though the poetry of Metaſtaſio's operas has always been admired as the beſt, and almoſt the only poetry truly lyrical in modern languages; yet it muſt be allowed that beautiful air, impaſſioned ſtrains, picturesque muſic, grateful harmony, fine voices highly cultivated, and great vocal talents, have rendered operas more attractive and captivating than the poetry alone, with all its high poliſh and beautiful ſentiments could have done. Metaſtaſio in his latter days joined in the complaints of French reformers of the Italian operas, againſt fine muſic and fine ſinging. No ſuch jealouſy appears in his letters to Farinelli, or to any other correſpondent, till he had ceaſed writing, when muſical compoſition and vocal talents were much more admired and applauded than at preſent.

MELOE, in *Geography*, a ſmall iſland in the Baltic; 14 miles E.N.E. of cape Lindeſneſs.

MELOE, the Bloſſom-eater, in *Natural Hiſtory*, a genus of inſects of the order Coleoptera; of which the character is antennæ moniliform; thorax roundiſh; head inflected and gibbous; ſhells ſoft and flexile. This genus is ſeparated into two diviſions, *viz.* into thoſe that have wings and thoſe that have none, of which the latter is ſubdivided. There are, in the ſeveral diviſions or ſections, about 36 ſpecies: of theſe only four are common to our own country, the others are diſtributed over the globe.

Section A. The inſects of this diviſion have no wings, and their ſhells are abbreviated.

Species.

* PROSCARABÆUS. This ſpecies is entirely of a blue-black, or dark violet colour. It inhabits Europe, and is deſcribed and figured in Mr. Donovan's Engliſh Inſects. Its trivial name is the "oil-beetle:" thorax narrower than the head; ſhells very ſhort and oval; abdomen long; the female is thrice as large as the male. It is found very frequently in the ſpring of the year in our own fields and paſtures creeping ſlowly, the body appearing to be ſo much diſtended with eggs as to cauſe the inſect to move with great difficulty. When touched it exudes a yellowiſh moiſture like oil from its pores, whence it derives its name, which was formerly celebrated for its ſuppoſed efficacy in the rheumatiſm, applied to the parts in the form of an embrocation. It has been likewiſe recommended as a remedy in hydrophobia.

* VARIEGATUS. This is of a dull green; thorax edged with red; ſhells punctured; inhabits Europe; the antennæ are purple; head and thorax dull green, edged with purpliſh red; the ſhells are ſhort, very minutely punctured; body large, above variegated with red, green, and copper, beneath and legs purple.

MAJALIS. Dorſal ſegments of the abdomen red. It inhabits divers parts of Europe, and very much reſembles the proſcarabæus, and has been thought to be only a variety of it.

MARGINATA. Black; thorax and ſhells edged with ferruginous; it inhabits Italy; the ſhells are ſhort, ſmooth, coriaceous; the abdomen and legs are black.

* PUNCTATA. Black; thorax and ſhells with minute punctures: inhabits England.

* TECTA. Blue-black; ſhells nearly as long as the abdomen; antennæ thicker in the middle: it inhabits Europe, is ſmaller than the proſcarabæus, and differs in the ſtructure of the antennæ, having the ſhells nearly as long as the abdomen.

Section

Section B. Winged; ſhells as long as the abdomen; divided into

α, Jaw horny, bifid, containing 26 ſpecies, and conſtituting the tribe *Mylabris* of Fabricius; and

ϐ, Jaw linear, entire; containing four ſpecies, which are comprized in the *Cecroma* of Fabricius.

Species in ſubdivion α, Jaw horny, bifid.

FASCIATA. Black; ſhells with a yellow band in the middle. Is found in India; head black; eyes teſtaceous; thorax black, with a ferruginous ſpot on each ſide; wings hyaline, with ferruginous ribs and veins.

CICHOREI. Black; the elytra yellow, marked with three black bands. It is a native of Aſia and the eaſtern parts of Europe. It is uſed in medicine among the Chineſe. The antennæ are ſometimes yellow at the tips. Found on the cichoreum or ſuccory, and varies much in the colour of the ſhells and diſpoſition of the bands.

PRÆUSTA. Black; tip of the ſhells teſtaceous, with a black ſpot: inhabits Barbary and is found among corn.

MARGINALIS. Black; ſhells with a ferruginous margin; inhabits Barbary, and, like the other, is found among the corn.

ALGIRICA. This alſo is black; ſhells teſtaceous, immaculate: it is found in various parts of India.

CAPENSIS. Black; ſhells with ſix yellow ſpots, the firſt is curved: it inhabits the Cape of Good Hope.

HERMANNIÆ. Villous, black; ſhells with a yellow ſpot at the baſe and two indented yellow bands. It inhabits Guinea; reſembles the cichorei, but is not half ſo large. The antennæ are black, ferruginous at the tip; head and thorax black with a few cinereous hairs.

PUNCTUM. Villous, black; ſhells with two bands, the firſt yellow with a black dot, the hinder one reddiſh. It inhabits Tranquebar.

DECEM-PUNCTATA. Black; ſhells teſtaceous, with five black dots: it is found in Italy.

QUADRI-PUNCTATA. Black; ſhells teſtaceous, with two black dots: inhabits Ruſſia and reſembles the laſt.

TRI-MACULATA. Black; ſhells yellow, with a brown band and common dot. It inhabits the Eaſt. The ſhells have a common brown ſpot in the middle, and a brown band behind which hardly reaches the outer margin.

ARGENTATA. Covered with ſilvery down; the ſhells have yellowiſh ſpots, moſt of them connected at the margin. It inhabits Senegal; the antennæ are ferruginous; the ſhells have a ſmall yellowiſh ſpot at the baſe; three marginal ones and one near the tip all ſurrounded with a black ring; the tip is yellowiſh, having a ſmall black dot in the middle; the legs are ferruginous.

AMERICANA. Black; thorax ſemi-circular; the ſhells have three yellow bands. It inhabits America. The tip of the antennæ is clavate.

INDICA. This ſpecies is black; the ſhells are yellowiſh, fulvous behind, with a black dot and three-lobed ſpot at the baſe, indented band in the middle and ſemi-lunar margin at the tip. It is found in India.

ELONGATA. Gloſſy-black; ſhells yellow varied with blue.

AUREA. Green-gold; ſhells fulvous.

ARCUATA. Black, hairy; ſhells with a curved yellow ſpot on the fore-part, and two waved yellow bands. Antennæ black, clavate at the tip.

BI-FASCIATA. Black, hairy; ſhells with a yellow round ſpot on the fore part and at the outer angle, and two yellow bands. It is found in India. Antennæ yellow; baſe of the ſhells piceous. The yellow ſpot at the angle of the ſhells is ſometimes wanting.

TRI-FASCIATA. Steel-blue, with a greeniſh ſilky gloſs; ſhells grey, with two greeniſh-black bands, one of them common. It inhabits near the Caſpian ſea.

ARATA. Deep gloſſy-black; ſhells with a yellow waved band towards the tip. It inhabits near the Caſpian ſea; the antennæ are clavate at the end; the legs ſecrete a kind of oil.

NECYDALEA. Black; ſhells red, a little ſhorter than the abdomen, diſtinct at the tip. It is found in Ruſſia.

PENNSYLVANICA. This ſpecies is entirely black and opaque: it inhabits Pennſylvania in America.

CHLOROPTERA. Black, ſubvillous; ſhells yellow: it inhabits France. The firſt joint of the antennæ is three times as large as the reſt.

MELANURA. Shells yellow, with four black ſpots, the tip black; antennæ clavate: it inhabits Calabria.

OCHROPTERA. Black; ſhells ſaffron, black at the baſe, on each ſide before and behind the middle is a ſaffron dot, with a black interrupted band and tip.

BICOLOR. Black; ſhells yellow, with a black dot on each ſide at the baſe; the tip and band in the middle, which is broader at the edges, are black.

Species, in ſubdiviſion ϐ, Jaw linear and entire.

SCHÆFFERI. Green; antennæ and legs entire. Inhabits Europe. Shanks and tarſi of the male dilated, appendaged.

VAHLII. Green; antennæ and legs black: an inhabitant of Barbary. Abdomen reddiſh at the baſe.

SCHRÆBERI. Green; antennæ, legs, and three ſegments of the abdomen, yellow.

GOUANI. Black; ſhells with a ſanguineous band and tip.

The larvæ as well as the perfect inſects of this genus feed on leaves.

The officinalis cantharis, or Spaniſh-fly, was till very lately ſuppoſed to be a meloe, and indeed is generally ſo arranged in our pharmacopeias; but more minute and accurate obſervations have ſhewn that it is a ſpecies of the LYTTA genus; which ſee.

MELOLONTHA, the name of a very peculiar ſort of beetle, which is found in all parts of England, and in many other countries among trees and hedges. The French call them *banneton*, and we *cock-chafers*, *dorrs*, and by many other names. The name melolontha is as old as Ariſtotle, and is given this creature from its feeding on the bloſſoms of the crab or wild apple. We have, of late years, had great damages done by the grubs of theſe beetles working under ground; but in Ireland they have been uſed to come in ſwarms, in certain years, in the beetle ſtate, and have been ſo terrible to that country, that the people have called them locuſts.

The firſt time they are remembered by authors to have appeared in this vaſt abundance, in that country, was in the year 1688. They then appeared in the ſouth-weſt part of the county of Galway; they appeared firſt upon the coaſt, and were brought by a ſouth-weſt wind, a wind ſo common there, that it may almoſt be called the trade wind of Ireland; from the coaſt they ſoon ſpread over the inland parts of the country, and were ſeen every where in ſuch numbers, as were ſcarcely to be conceived. They never ſtirred in the day time, but were ſeen covering the leaves and branches of trees and hedges, and in many places hanging down in prodigious cluſters on one another's backs, in the manner of bees when they ſwarm. As ſoon as the ſun ſet, they uſed to leave the hedges, &c. and take wing, gathering in bodies, and making a humming confuſed noiſe like that of drums at a diſtance. They ſometimes formed bodies together, that darkened the air for three or four miles ſquare. They flew ſo low ſometimes, that it was ſcarcely poſſible for a perſon going along to make his way through them; and by ſtriking againſt the faces and necks of women and children, they did much miſchief, every one leaving a mark behind it; and thoſe of this ſex or age, who had been among them, came home all over bruiſes.

This, however, was little to the miſchief they did the fields; for though the middle of the ſummer was the ſeaſon in which they came, they had in a few days eaten up all the leaves of the trees ſo completely, that they all looked as bare as in the depth of winter. The noiſe they made, while eating in vaſt numbers together, was like that of ſawing timber. The gardens fared no better than the hedges, for they eat up leaves, young ſtalks, and fruit, and every thing that was green and ſoft there, and left only a parcel of naked ſticks behind them. Many of the trees, thus ſtripped, wholly periſhed. Phil. Tranſ. N° 234. See SCARABÆUS *Melolontha.*

MELOMELI, a word uſed by the ancients to expreſs honey impregnated with quinces.

MELON, in *Gardening*, the common name of a well known plant, which is much employed in forcing-frames, &c. See CUCUMIS, and FORCING.

MELON-*ground*, the ſpace or portion of ground in the kitchen-garden, or other place, which is appropriated to the culture of melons and other vegetables that require artificial heat. See GARDEN, and MELONARY.

MELON-*thiſtle*, the common name of a plant of the thiſtle kind. See CACTUS.

MELON, *Water*, or *Citrul*. See CUCURBITA.

MELONS, *Petrified*, a name given by the people who have written books of travels, &c. to certain ſtones found on mount Carmel. The monks who inhabit that mountain at this time, and who pretend to be the followers of Elias the prophet, tell a legendary ſtory about theſe ſtones, which has given occaſion to the name. They ſay that when Elias lived on that mount, a certain gardener paſſing by his cave with melons, the prophet aſked one of them; but the fellow replying, that they were not melons, but ſtones that he carried, the prophet miraculouſly fulfilled the ſaying, and converted them into ſtones. Travellers who are fond of theſe ſtories were uſually glad to pick up one of theſe ſacred ſtones as they went on; and the monks have been careful enough to gather all they could find for the better opportunity of obliging their viſitors; ſo that though they were once very common, they are now only to be had by the favour of theſe people.

Breynius is the only author who has given a good account of them; he ſays, that they are ſpheric or ſpheroidal ſtones, of various ſizes, from that of a hen's egg to that of the largeſt melon, or even more than that. They are generally found bedded in a very hard ſand-ſtone, of a greyiſh or aſh-colour; but they come out whole on breaking the ſtone, and are of a ſmooth ſurface; a greyiſh colour, or ſometimes a browniſh ferruginous hue. When they are broken, there is always a cavity found in them, ſometimes regular and even, ſometimes very irregular, and generally proportioned to the bigneſs of the ſtone. This cavity is lined on both ſides with minute cryſtals, which are very bright and pellucid, and have their points ſtanding toward the centre of the cavity. This ſubſtance of the ſtone itſelf approaches to the nature of marble, of a yellowiſh colour, and capable of a good poliſh; when wrought looking very like the Florentine marble. This is a cruſt of about half an inch or an inch in thickneſs, according to the bigneſs of the ſtone, and ſometimes this is covered with a paler-coloured cruſt, of the thickneſs of a ſtraw, which in ſome degree reſembles the bark or rind of the fruit. Theſe ſtones are truly a ſort of concave natural nodules, of the nature of our hollow flints. They have had no fruit for their matrix, nor have ever had any of the ribs and furrows which the melon has, nor any mark of the ſtalk; and within they have neither the natural diviſions of the melon, nor any thing reſembling the ſeeds. It is not only the want of many parts abſolutely eſſential to the fruit ſuppoſed to be petrified, which ſhews that opinion to be erroneous; but the courſe of nature, in petrifactions in general, argues alſo greatly againſt it.

The things we meet with, in this ſtate, are all of them ſuch as are naturally hard, dry, and permanent, and none of the tender and ſucculent bodies, ſuch as the melon, and the like fleſhy fruits, which muſt neceſſarily rot in the water that conveys the ſtony matter, before it could at all enter their pores. And the ſtones are certainly analogous to thoſe concave nodules of a ferruginous colour, in the cavities of which amethyſts are produced; and to that genus of ſtones which Woodward calls concave cryſtalline balls, common in many parts of the world.

The fallacy of an extravagant opinion in regard to foſſils of any particular form, is not peculiar to theſe ſtones, as witneſs the ſmall ſhells petrified and found in Egypt, which from their flat and roundiſh ſhape, are ſaid to be the lentiles, which the children of Iſrael eat when making the pyramids: the *cornua Ammonis*, which is the remains of a ſea-ſhell, and yet is ſuppoſed to be a petrified ſerpent; the *nummi minerales*, which are the operculums of ſhell-fiſh, but are generally ſuppoſed by the vulgar, about the places where they are found, to be medals and coins petrified with lying in the earth, and many the like follies. Breyn. de Melon. Petr. Mont. Carm.

MELONARY, in *Gardening*, the portion of ground in the kitchen-garden principally allotted for the buſineſs of early and general hot-bed work, in the culture of melons and cucumbers as well as occaſionally in other framing culture.

Theſe compartments are moſtly incloſed by ſome ſort of fence, and are particularly convenient and uſeful, as in the practice of hot-bed culture there is unavoidably a conſiderable littering occaſioned at times, by means of the neceſſary ſupplies of hot-dung, ſtraw, litter, and other materials, both in the making of the beds and after-culture; which by this means being confined to a particular part, the whole is performed more conveniently, and without incommoding the economy of the other parts of the garden.

They are alſo very uſeful when properly choſen in the drieſt and warmeſt ſituations, in the advantage of having the hot-beds on dry ground, and ſheltered from cutting winds, with the full benefit of the whole day's ſun, as well as in being more ſecure. In conſiderable gardens, the places allotted for this uſe are ſometimes of ſuch extent, as to have the hot-houſes, or forcing houſes, and other appurtenances of that kind, where culture by artificial heat is required, near together, by which time and trouble is ſaved, and great advantage in other reſpects gained.

In the choice of a place for this purpoſe, ſome part of the warmeſt, beſt-ſheltered, dry quarter of the garden, which is well defended from the northerly and north-eaſterly winds, not liable to inundation or the ſtagnation of water, and conveniently ſituated for bringing in dung, tan, earth, &c. ſhould be fixed upon. And if, with theſe advantages, it lies rather a little higher or very gently ſloping towards ſome lower part, it will be more proper, eſpecially when towards the full ſun from riſing to ſetting, ſo as to admit of ranging the

the hot-beds longitudinally eaſt and weſt, or as nearly in that direction as poſſible. See Garden.

With reſpect to the extent or dimenſions, they muſt be according to the quantity of hot-bed framing required, as from two or three, to ten, twenty, or thirty frames, or more; and ſometimes alſo for hot-bed ridges for hand-glaſſes in the ſame proportions. They may of courſe be from two or three to five or ten rods ſquare, or to that of a quarter, or half an acre, or more; in which, beſides the part immediately allotted for the hot-beds, it is convenient to have room for the previous preparation of the dung, &c. for earthing the hot-beds. And in reſpect to form the moſt eligible ſhape is that of a ſquare, either an equal or an oblong ſquare.

When incloſed, the fences may be ſix, ſeven, or eight feet high in the northerly or back part and five or ſix in front, the ſides correſponding, though when extenſive they may be nearly of equal height all around. And the internal part, or immediate place for the hot-beds, even when dry, ſhould be a little elevated to throw off the falling wet of heavy rain, &c. and when unavoidably low, or liable to be wet in winter or ſpring, be raiſed, with ſome dry materials, conſiderably above the general level, that the hot-beds may ſtand dry, as well as to afford advantage in performing the buſineſs of cultivation.

The ground for the immediate place of the hot-beds may generally remain even or level; ſome, however, form ſhallow trenches the width and length of the intended hot-beds, as from ſix to twelve inches deep, and make the lower part of the bed in the trench; which, however, is more proper in a dry or ſomewhat elevated ſituation than in low or wet ground, as water is apt to ſettle in the bottom, and chill the beds, occaſioning the heat to decline ſuddenly.

Beſides, by having the hot-beds wholly above ground, there is a better opportunity of applying the occaſional linings quite from the bottom upwards. By proper attention in the conſtruction of the different parts of theſe grounds and in the building of the fences, they may alſo be rendered highly uſeful in raiſing various kinds of fruit, which could not otherwiſe be the caſe.

MELONGENA, in *Botany*, a word of Arabian origin, according to Ambroſinus, from whence the Italian *Melanzana* ſeems to have come, rather than from *Mala inſana*, as is commonly ſuppoſed; the Egg Plant. This fruit is ſaid to be much uſed for food among the Arabs. It is alſo, according to Matthiolus, commonly eaten in Italy, being dreſſed in the form of fritters, with flour and oil, or butter, and ſeaſoned with pepper and ſalt. That author gives *Melongena* as the vulgar Lombard name of the fruit, which he ſays is called by the Tuſcans *Petranciani*. We cannot but ſuſpect the Latin name *Mala inſana*, Mad Apples, which this fruit does not appear in any manner to deſerve, to have been a corruption of the Arabic or Italian appellation, rather than the reverſe. See Solanum.

MELOPEPO, from *Melo*, a Melon, and *Pepo*, a Pompion, the name of various round kinds of Gourd. See Cucumis.

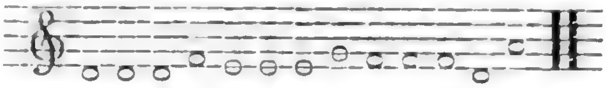
MELOPŒIA, Gr., *Melopée*, Fr., a term in the muſic of the ancients, which implied the ſelection and arrangement of ſuch ſounds as were fit for ſong. The word is derived from μελος, *cantus*, οιεω, *facio*, *fingo*, *fabrico*, *compono*, "to build the lofty rhyme."

Melopœia had its particular rules, ſeveral of which are come down to us, and are ſtill clear and intelligible: ſuch as that an air, or piece of melody, ſhould be compoſed in ſome particular genus, and be chiefly confined to the ſounds of ſome certain mode. As to the ſucceſſion, or order of theſe ſounds in the courſe of the air, that was in general confined to four kinds, which Euclid ſpecifies in his Harmonic Introduction. Theſe we ſhall endeavour to deſcribe with exactneſs, as they may throw ſome light upon ancient melody.

Euclid tells us, firſt, that ſounds may move either aſcending or deſcending regularly; as thus:

which was called ἀγωγη: ſecondly, by leaps of greater intervals than a ſecond; thus,

which was called πλοκη, *interwoven*: thirdly, by repeating the ſame ſound ſeveral times, which was called πεττεια, *iteration*; as in ſinging theſe notes,



and fourthly, that ſounds may be ſuſtained in the ſame tone, which we call a *holding note*, and which the Greeks expreſſed by the word τονη.

There were many rules to be obſerved in moving by leaps, or disjunct degrees, the principal of which was to prefer, in general, conſonant to diſſonant intervals. It was likewiſe enjoined not to divide any two ſemitones into quarter tones, together, or two ſucceſſive tones into ſemitones, nor were two major thirds to follow each other.

But theſe, and a great number of other rules laid down by Ariſtoxenus, with reſpect to the ſucceſſion of intervals, were all derived from the genera, the rules for which were rules for melody. The diatonic genus of the ancients reſembled our natural ſcale in every particular; and it is allowed by Ariſtoxenus even that three tones may ſucceed each other, aſcending or deſcending, which is all that is allowed in our diatonic, except in minor keys, where we aſcend to the octave of the key note by a ſharp ſeventh, which the ancients ſeem never to have admitted.

A further detail or explanation of theſe rules would not make the matter much clearer; however, there are ſome particulars collected together in the firſt book of Ariſtides Quintilianus, that ſeem to merit attention.

He ſets off by dividing Melopœia into three ſpecies, taken from the great and general ſyſtem, which he names after the ſounds called *hypate*, *meſe*, and *nete*; that is, loweſt, middle, and higheſt; and theſe denominations reſembled, with reſpect to melody, our diſtinctions of baſe, tenor, and treble.

With regard to modulation in melody, he has the ſame diſtinctions as Euclid for the ſeveral ſpecies, though he differs a little from him in his manner of defining them: but theſe differences are of ſmall importance to us now; and indeed the authority of Euclid is ſo ſuperior to that of Ariſtides Quintilianus, that nothing which can be cited from him would have weight ſufficient to invalidate the teſtimony of ſo exact and reſpectable a writer.

However, the moral diſtinctions of Melopœia to be found in Ariſtides Quintilianus are ſo curious and fanciful, that we ſhall inſert a few of them here.

He allows of three modes (τροποι) or ſtyles of Melopœia: the *dithyrambic*, or bacchanal; the *nomic*, conſecrated to Apollo;

Apollo; and the *tragic;* and acquaints us that the first of these modes employed the strings, or sounds, in the middle of the great system; the second, those at top; and the third, those at the bottom.

These modes had other subaltern modes that were dependent on them; such as the *erotic*, or amorous; the *comic;* and the *encomiastic*, used in panegyrics. All these being thought proper to excite or to calm certain passions, were, by our author, imagined to have had great influence upon the manners (ἤθη); and, with respect to this influence, Melopœia was divided into three kinds: first, the *systaltic*, or that which inspired the soft and tender passions, as well as the plaintive, or, as the term implies, such as affect and penetrate the heart; secondly, the *diastaltic*, or that which was capable of exhilarating, by kindling joy, or inspiring courage, magnanimity, and sublime sentiments; thirdly, the *hesuchastic*, which held the mean between the other two, that is, which could restore the mind to a state of tranquillity and moderation.

The first kind of Melopœia suited poetical subjects of love and gallantry, of complaint and lamentation; the second was reserved for tragic and heroic subjects; the third for hymns, panegyrics, and as a vehicle of exhortation and precept.

All these rules concerning the ancient Melopœia afford only general notions, which, to be rendered clear and intelligible, would require particular discussions, as well as illustrations by example; but the Greek writers on music have absolutely denied us that satisfaction, reserving, perhaps, when they published their works, all such minutiæ for the lessons which they gave their scholars in private; for in no one of the seven treatises upon ancient music, collected and published by Meibomius, is a single air or passage of Greek melody come down to us; which is the more extraordinary, as there are few treatises upon modern music, without innumerable examples in notes, to illustrate the precepts they contain.

But whatever were the rules for arranging different sounds in such order as would flatter the ear in the most agreeable manner, it is easy to imagine that this regular disposition, and beautiful order of sounds, constituted nothing more than the mere body of melody, which could only be animated and vivified by the assistance of rhythm or measure. See Music *of the Greeks*.

MELORA, in *Geography*, a small island in the Mediterranean, near the coast of Etruria; 4 miles W. of Leghorn.

MELOS, in *Ancient Geography*, one of the Grecian islands, situated about 24 miles from cape Scyllæum, in the Peloponnesus, south-west of the isle of Siphnos, west of that of Sicinos, and east of the promontory of Malea, in Laconia. It was estimated at about 60 miles in compass, and, according to Pliny, it was almost round. This island, though small, made a very considerable figure in the flourishing ages of Greece. It enjoyed its liberty, says Thucydides, 700 years before the Peloponnesian war. The inhabitants were originally Lacedæmonians, and therefore, in the time of the war just mentioned, refused to join the Athenians, declaring that they would maintain a strict neutrality. They suffered severely for their attachment to Lacedæmon. All who were able to bear arms were put to the sword; the women and children were carried into Attica, and sold for slaves. The island being thus desolated, a new colony was sent thither from Athens. But not long after, Lysander, the Lacedæmonian general, having obliged the Athenians, in their turn, to surrender at discretion, released the captive Melians, and restored them to their native country, after having expelled the Athenian colony. Melos afterwards experienced the common fate of the other islands of the Ægean sea, being reduced, with them, to a Roman province. This island abounded with iron mines, and was formerly famous for its wine and honey. The pastures and mineral waters of this island were also commended; and the alum of Melos was in great repute among the Romans, and preferred by them to that of any other country, except the Egyptian. See Milo.

Melos and *Melodias*, which Meibomius has rendered by the Latin words, *modulatio* and *cantilena*, had no other signification than the change of sounds in singing, or, as we should call it, melody; and this is clear from a passage in Bacchius senior, where, in his Introduction to the Art of Music, by question and answer, it is asked, How many kinds of modulation there are? He answers, four; and these, he says, are *rising*, *falling*, *repeating* the same sound to different words, and *remaining upon*, or *holding out*, a musical tone. See Melopœia.

MELOSIS, from μηλη, *a probe*, in *Surgery*, the examination of a diseased part with a probe.

MELOT, John Baptist, in *Biography*, a learned Frenchman, was born at Dijon in 1697, and died at Paris in 1760. He was librarian to the king, and wrote some papers in the "Memoirs of the Academy of Inscriptions," of which he was a member. He was also editor of Jourville's Life of St. Louis, with a glossary.

MELOTHRIA, in *Botany*, a name borrowed by Linnæus, in his *Hortus Cliffortianus*, from the μηλωθρον of Dioscorides, one of the synonyms of his αμπελος λευκη, or White Vine, which is supposed to be the *Bryonia*, a plant of the same habit and natural order as the present. Linn. Gen. 24. Schreb. 32. Willd. Sp. Pl. v. 1. 189. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 78. Juss. 395. Lamarck Illustr. t. 28.—Class and order, *Triandria Monogynia*. Nat. Ord. *Cucurbitaceæ*, Linn. Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, bell-shaped, swelling, five-toothed, deciduous. *Cor.* of one petal, wheel-shaped; tube the length of the calyx, to which it is on every side united; limb flat, in five deep very blunt segments, dilated outwards. *Stam.* Filaments three, conical, inserted into the tube of the corolla, and equal to it in length; anthers of two roundish lobes, compressed. *Pist.* Germen almost entirely inferior, ovate-oblong, pointed; style cylindrical, the length of the stamens; stigmas three, thickish, oblong. *Peric.* Berry ovate-oblong, internally divided into three parts, without partitions. *Seeds* several, oblong, compressed.

Obs. Linnæus remarks that he once saw two flowers with stamens only.

Ess. Ch. Calyx bell-shaped, five-cleft. Corolla wheel-shaped, of one petal. Berry of three cells, with many seeds.

1. M. *pendula.* Pendulous Melothria, or American Bryony. Linn. Sp. Pl. 49. (Bryonia olivæ fructu rubro, minor; Plum. Ic. 55. t. 66. f. 2. Cucumis parva repens virginiana, fructu minimo; Pluk. Phyt. t. 85. f. 5.)—Native of North America and the West Indies. *Root* annual. *Stem* slender, branched, climbing by means of simple tendrils. *Leaves* heart-shaped, five-lobed, obscurely toothed, rough, on thick twisted stalks. *Flower-stalks* axillary, solitary, simple, capillary, about an inch long. *Flowers* small, yellow. *Fruit* red, the size and shape of a small olive. Jussieu says two of the filaments bear each two anthers, which is the case in *Bryonia*, to which genus this plant is certainly very nearly akin. Vahl having omitted the genus in its proper place, had perhaps a design of uniting it to *Bryonia*.

MELOTIS,

MELOTIS, a word used by the chirurgical writers to express a small probe, properly one intended to be used only to the ear.

MELOZZO, Francesco, in *Biography*, an historical painter, who flourished about 1471. He is celebrated as being one of the first who introduced the fore-shortening of figures upon ceilings, so as to make them appear ascending or descending; and a picture of his, over the great altar in the church of the Apostles at Rome, which represents the ascension of our Saviour, is celebrated with the warmest praises. Vasari says, that the figure of Christ seems to pierce the roof. This work was painted for cardinal Riario, nephew of Nicholas V. about 1472; and when that chapel was repaired, it was cut out and placed in the Quirinal palace, where it is still seen with this epigraphe: "Opus Melotii Forotiviensis, qui summos fornices pingendi artem vel primus invenit vel illustravit." Some heads of the apostles were likewise preserved in the Vatican: they are well turned, almost always fore-shortened, and wrought with great finish, diligence, and grace. It is to be lamented that so uncommon a genius has not met with an exact historian, who would have informed us of his preparatory studies. He is best known by the name of Melozzo da Forli.

MELPIGNANO, in *Geography*, a town of Naples, in Otranto; 9 miles W.N.W. of Otranto.

MELPILLY, a town of Hindoostan, in the Carnatic; 25 miles N. of Nellore.

MELPOMENE, the name of one of the nine Muses; who is represented with a mask, to denote her presiding over the stage; and distinguished from Thalia, the comic Muse, by greater dignity in her look, stature, and dress. Melpomene was supposed to preside over all melancholy subjects, as well as tragedy. See Horace, lib. i. od. 24. v. 4. lib. iii. od. 30. v. ult.

MELRICKSTADT, in *Geography*, a town of the duchy of Wurzburg, on the Streys; 19 miles N. of Schweinfurt. N. lat. 50° 27′. E. long. 10° 27′.

MELROSE, a considerable town, and a free borough of barony, situated on the banks of the river Tweed, in the shire of Roxburgh, Scotland. The river divides the town, which extends about a mile in length, into two parts. It is governed by a magistracy, elected annually by the burgesses; and, considering its inland position, may be regarded as a flourishing place. The whole parish, according to the parliamentary returns of 1801, contains 1355 houses, occupied by a population of 6947 inhabitants, *viz.* 3300 males and 3647 females. Of this number, 668 were reported as being employed in different branches of trade, but principally in the manufacture of linen and coarse woollens.

The parish of Melrose and its immediate neighbourhood are distinguished by numerous and splendid remains of antiquity. The abbey of Melrose is one of the most remarkable monastic structures in Scotland. Its original foundation probably took place towards the close of the sixth century. In the works of the venerable Bede, we have an account of the situation of the more ancient edifice, on the bank of the Tweed, as likewise of its abbots. This place was a celebrated school for learned and religious men, and seems to have continued to flourish till the reign of king David, by whom the new abbey was founded, in the year 1136. The former establishment was at Old Melrose, the name of which still serves to remind the inhabitants that they tread on ground rendered sacred by the piety of their ancestors. The foundation of the wall, which inclosed the ancient monastery and its precincts, can still be discovered, stretching across a sort of promontory, formed by a curvature of the Tweed; but all vestiges of the buildings are entirely lost. It seems probable, therefore, that they were of little comparative magnitude, and might perhaps have been constructed only of wood, or other perishable materials, as most of the churches of that age undoubtedly were. Of a similar description was the edifice erected by king David, which was rebuilt first in the thirteenth century, and again after the accession of Robert Bruce, who granted a revenue for its restoration. This last appears, from its ruins, to have been a truly magnificent and spacious structure. Indeed the size and workmanship of its columns, its symmetrical proportions, and the quality of the stone of which it is constructed, entitle it to rank among the most superb edifices which devotion or superstition has reared in Great Britain. From the charters granted to this monastery by different Scottish monarchs, its inmates appear to have been monks of the Cistercian order, and to have enjoyed a pre-eminence or species of jurisdiction over all their brethren in Scotland. Among the more distinguished of these monks was the celebrated St. Cuthbert, who entered as a monk under Boisil, about the year 601, and had the honour of founding the bishopric of Durham.

The church belonging to this abbey constitutes the most entire part of its ruins. It was built in the form of St. John's cross, and is dedicated to the Virgin Mary. The present extent of this building is 258 feet in length, and 137½ in breadth; its circumference measuring 943 That these are not the original dimensions, however, are evident from the state of the western division, the greater part of which has been destroyed, and that so completely, that it is impossible to determine to what distance it reached. Both the exterior and the interior of this edifice were formerly adorned with a variety of sculptured figures of men and animals. Many of the former, in particular, were destroyed in the reigns of Henry VIII., Edward VI., and Elizabeth, whose statesmen and warriors were no less egregious fanatics than the infuriated Scotch reformer John Knox, in whose time, likewise, this building sustained much additional injury. The niches in which they stood display much curious and beautiful workmanship. The tower, which rose from the middle of the cross or transept, was a noble piece of architecture. Part of it still remains, but the spire is entirely gone. The east window is most magnificent, and consists of four mullions with tracery, variously ornamented. On each side appear several elegant niches, and on the top is the figure of an old man, with a globe in his left hand, resting on his knee; and another of a young man on his right; both in sitting postures, with an open crown over their heads. Underneath this window, in the inside, stood the altar-piece. A great number of piscinas, niches, &c. excellently sculptured, are dispersed throughout the church. Many of the pillars are perfect and beautiful, and the embellishments upon them still seem as if newly executed; a decisive evidence of the excellence both of the stone and of the workmanship. Part of this church continues to be used for divine service.

The ruins yet standing, besides the church, consist chiefly of a part of the walls of the cloisters; the other buildings, of which there were many, being almost entirely levelled with the ground. All of these, together with the gardens, and other conveniences, were enclosed within a lofty wall, which extended about a mile in circuit. A large and elegant chapel formerly occupied the scite of the present manse; and to the north of this house there has been lately discovered the foundation of a curious oratory, or private chapel, from which

which was dug up a large ciftern, formed from one ftone, having a leaden pipe appended to it, for the conveyance of water.

At fome diftance to the fouth of this town are the three Eldon-hills, on the northernmoft of which is a large Roman encampment, and below it are the remains of an extenfive Britifh fortrefs. Around this were feveral fmaller forts, alfo of Britifh origin, fome of which the Romans appear to have converted into more defenfible pofts. Three entrenchments on thefe hills were connected by a very fingular kind of military road, defcribed by Mr. Kinghorn, who furveyed it in 1803, as being in general about 40 feet broad, but in fome places 50, where the unevennefs of the ground required fuch a breadth. On each fide of this road is a ditch, from 12 to 28 feet wide, whence the earth is thrown up fo as to form a mound on the exterior fide. As this remain differs materially from all other Roman roads in this country, it feems probable that it has been the work of the Romanized Britons, during their contefts with the Picts and Scots, after the departure of their enlightened conquerors, whofe modes of warfare they would naturally endeavour to imitate. From the Britifh fort on Eldon-hills to the fortrefs on Caldfheds-hill there likewife runs a foffe and rampart, which feems to have been carried through the diftance between thefe fortreffes as a defenfible boundary. The great Roman road croffes the Tweed at the village of Galtonfide, a little above Melrofe. On the declivity of the hill, on which this village ftands, are the remains of a fpacious encampment. The ftone wall around it is ftill tolerably entire. Half a mile to the eaft is another entrenchment, called Chefter-Knows, which was probably the moft confiderable ftation they poffeffed in this part of the country, being nearly three-quarters of a mile in circumference. Chalmer's Caledonia, vol. ii. 4to. 1810. Beauties of Scotland, vol. ii. Sinclair's Statiftical Account of Scotland.

MELSACK, a town of Pruffia, in the province of Ermeland; 36 miles S.W. of Königfberg. N. lat. 54° 12′. E. long. 20 7′.

MELSO, a town of Italy, in Friuli; 9 miles N.W. of Udina.

MELT. See MILT.

MELTING-CONE, in *Affaying*, is a fmall veffel made of copper or brafs, of a conic figure, and of a nicely polifhed furface within. Its ufe is to receive melted metals, and ferve for their precipitation, which is effected, when two bodies melted together, and yet not mixing perfectly with one another in the fufion, feparate in the cooling into two ftrata, on account of their different fpecific gravity. This precipitation might be made in the fame veffel in which the fufion is performed; but then the melting-pot or crucible muft be broken every time to get it out, whereas the conic fhape, and polifhed furface of this veffel, makes it eafily got out without violence. The fhape of this veffel is alfo of another ufe in the operation; for by means of it, the heavy matter fubfiding to a point, is formed into a perfect and feparate regulus, even where the whole quantity, as is very frequently the cafe, has been but very fmall.

When the quantity of the melted matter is great, it is common to ufe, inftead of this cone, a large brafs or iron mortar, or any other conveniently fhaped brafs or iron veffel. It is neceffary, when the cone is of brafs, to be cautious that it be not made too hot; for the brittlenefs of that metal, when hot, makes it eafily break, on the ftriking with any force on that occafion, to make the melted mafs fall out.

Thefe, and all other moulds for the receiving melted metals, muft always be well heated before the mafs is poured into them, left they fhould have contracted a moifture from the air, or have been wetted by accident; in which cafe the melted metal will be thrown out of them with great violence and danger. They ought alfo to be fmeared over with tallow on their infide, that the regulus may be the more eafily taken out of them, and the furface of the mould not corroded by the melted mafs poured in.

If a very large quantity of a metal is, however, to be received into them, and efpecially if any thing fulphureous have place among it, this caution of tallowing the moulds does not prove fufficient; for the large quantity of the mafs makes it continue hot fo long, that this becomes but a flight defence to the furface of the mould. In this cafe the affayer has recourfe to a lute, reduced to a thin pap with water, which being applied in form of a very thin cruft, all over the infide of the cone, or mould, foon dries up, indeed, but always preferves the fides of the veffel from the corrofion of the mafs. And this caution is found neceffary, even when pure copper is melted alone, without any mixture of fulphur.

MELTING *Fire*. See FIRE.

MELTING, *Surveyor of*. See SURVEYOR.

MELTON-MOWBRAY, in *Geography*, in ancient writings called Medeltune and Meltone, a fmall market-town, in the hundred of Framland, and county of Leicefter, England, is fituated in a vale on the banks of the river Eye, 15 miles from Leicefter, and 104 from London. Connected with this town are three bridges over the rivers Eye and Sealford. Thefe are repaired, and the ftreets preferved in good condition, with lamps, &c. from the rents arifing out of the town eftates. The church, which Leland calls "a faire paroche church, fumtime an hofpital and cell to Lewis in Suffex," is a fpacious ftructure, confifting of a nave, aifles, tranfepts, and chancel, with a tower in the centre, and a porch at the weft end. The latter is a peculiar feature to the building, and has an elegant door-way, with an ozee arch. Above this porch is the large weftern window, comprifing five lights, with four lofty mullions. The whole church is crowned with an embattled parapet, and at each angle is a crocketed pinnacle. The tower confifts of two well-proportioned ftories above the church. The poor of this town derive affiftance from feveral charitable benefactions; among which are fome public fchools. So early as the reign of Henry III. we find thefe taken under the immediate patronage of that monarch. A free fchool for girls was eftablifhed here in 1795. In the population report of the year 1801, Melton-Mowbray was ftated to contain 348 houfes and 1766 inhabitants. The market-day is Tuefday; and at every alternate market is generally a large fhow of cattle. Here are alfo three annual fairs, and a ftatute for hiring fervants.

Among the more eminent natives of Melton were John de Kirkby, who was appointed keeper of the great feal in 1272, lord high treafurer in 1283, and bifhop of Ely in 1286; William de Melton, fucceffively lord high treafurer, lord chancellor, and archbifhop of York, in the reigns of Edward II. and III.; John Henley, better known by the popular appellation of Orator Henley, who diftinguifhed himfelf, about the middle of the laft century, by his eccentric lectures. See HENLEY.

At Burton-Lazars, a hamlet to Melton, about two miles from the town, an hofpital, for leprous brethren of the order of St. Auguftine, was founded in the reign of king Stephen, by a general collection throughout England, but chiefly by the affiftance of Roger de Mowbray. In adopting

ing this situation, the founders were probably influenced by a bath or spring, the waters of which were formerly in high estimation for the disorder called leprosy, and are still said to afford considerable benefit to persons in scorbutic complaints. A bathing-room and drinking-room were built here about the year 1760, for the accommodation of the afflicted visitors. Nichols's History of Leicestershire, vol. i. Beauties of England and Wales, vol. ix., by J. Britton.

MELTZ, a town of Bavaria; 10 miles N. of Bamberg.

MELVIL, *Sir* JAMES, in *Biography*, a statesman and historian, was born at Hall-hill, in Fifeshire, in 1530. At the age of fourteen he entered the service of the queen-regent, and was appointed page to her daughter Mary, then wife to the dauphin of France. After passing some time in her service, she permitted him to enter into that of the constable Montmorenci, who sent him over to Scotland in 1559, in order that he might obtain a faithful account of the state of parties in that kingdom. Having remained several years in the employ of that nobleman, he visited the court of the elector palatine, who detained him three years in various negociations with the German princes. He then passed through Italy and Switzerland, and returned to the elector's court, where he found a summons from Mary, who had now returned to take possession of the crown of her native country. He followed her to Scotland, in 1561, in the character of gentleman of the bed-chamber, and was employed by her confidentially in various important affairs till her imprisonment in Lochleven castle. He had been appointed one of her privy-counsellors, and was sent more than once to the court of Elizabeth. He maintained a correspondence in England in favour of Mary's succession to the crown of that kingdom, but upon the manifestation of her unhappy partiality for Bothwell, after her husband's murder, he ventured upon the strongest remonstrances with her. She not only disregarded these admonitions, but communicated them to Bothwell, in consequence of which the faithful Melvil was obliged, for some time, to absent himself from court. When Mary was detained a prisoner in England, she recommended her faithful servant to her son James VI., who consulted him and made use of his services till he acceded to the throne of England. He was ever the adviser of prudent and moderate measures, and retained the esteem of his royal master, who would willingly have taken him to England as one of his ministers. Melvil, however, thought himself too far advanced in years for so important a change in his habits, and he retired to his family seat, where he died in the year 1606. He left behind him in MS. an historical work, which came into the possession of his grandson, and was published in 1683, by Mr. George Scott, under the title of "Memoirs of sir James Melvil of Hall-hill, containing an impartial account of the most remarkable affairs of state during the last age, not mentioned by other historians, more particularly relating to the kingdoms of England and Scotland, under the reigns of queen Elizabeth, Mary queen of Scots, and king James. In all which transactions the author was publicly concerned." To this work the reader is referred for more information relating to the author: and also to Robertson's History of Scotland. A brother of sir James was also in the service of Mary, and is probably the sir Andrew Melvil who was present at her death.

MELVIN-LOUGH, in *Geography*, a considerable lake of Ireland, between the counties of Fermanagh and Leitrim, from which a small river flows to the bay of Donegal.

MELUING, a town of Norway, in the diocese of Drontheim; 32 miles W.N.W. of Romsdal.

MELUN, a city of France, and principal place of the department of the Seine and Marne, of which it is the capital, situated on the Seine; before the revolution it contained one collegiate and three parish churches, two convents and two abbies. It carries on a trade with Paris in corn, meal, wine, and cheese. The place contains 6124, and the two cantons, into which it is divided, 18,022 inhabitants, on a territory consisting of 287½ kiliometres, in 31 communes. N. lat. 48° 32′. E. long. 2° 44′.

MELYKUT, a town of Hungary; 16 miles E. of Baja.

MELYRIS, in *Natural History*, a genus of insects of the order Coleoptera; the generic character is, antennæ entirely perfoliate; head inflected under the thorax; thorax margined; lip clavate, emarginate; jaw one-toothed, pointed. There are three

Species.

VIRIDIS. Green; shells with three raised lines; it inhabits the Cape; antennæ black; thorax reflected at the edge, and grooved on the back, scutel small and round; shells rough.

NIGER. Black; shells with three raised lines. A specimen of this species of the melyris is in sir Joseph Banks' museum. It is only about one-third the size of the last; thorax a little prominent before; the shells rough.

LINEATUS; Green; shell with three raised lines, and one on each side the thorax: it is about half the size of the viridis; thorax grooved, with a raised line on each side; lines on the shells crenate.

MELZEN, or MELTZEN, in *Geography*, a town of Saxony, in Thuringia; six miles S. of Weissensels.

MELZO, a town of Italy; 14 miles N.E. of Milan.

MEMAUN, a town of Persia, in Khorasan; 18 miles E.S.E. of Velazghard.

MEMBERS, in *Anatomy*, the exterior parts, arising from the trunk or body of an animal like the boughs from the trunk of a tree.

In which sense, members, *membra*, amount to much the same with limbs, *artus*: though some make a difference between the two: restraining members more immediately to the fleshy parts which cover the limbs, and artus to the bones and nerves. Physicians divide the body into three regions or venters; the head, the breast, and the lower ventricle; and the extremities, which are the members. See EXTREMITIES.

MEMBER, in *Architecture*, denotes any part of a building; as a frieze, cornice, or the like.

MEMBER is sometimes also used for moulding.

MEMBER, in *Grammar*, is applied to the parts of a period, or sentence.

MEMBER is also used to denote some particular order or rank in a state or government: thus we say, member of a corporation, member of parliament, member of the council, &c.

MEMBERED, or MEMBRED, in *Heraldry*, is when the beak, or legs, or feet of an eagle, griffin, or other bird, are of a different colour from the rest of the body.

MEMBIG, in *Geography*, a town of Syria, in the pachalic of Aleppo; 30 miles N. of Aleppo.

MEMBRANA, in *Anatomy*. See MEMBRANE.

MEMBRANA *Arachnoidea*, one of the coverings of the brain and medulla spinalis. See BRAIN.

MEMBRANA *Conjunctiva*, the mucous membrane lining the eye-lids, and covering the anterior surface of the eye. See EYE.

MEMBRANA *Decidua*, one of the coverings of the ovum. See EMBRYO.

MEMBRANA *Hyaloidea*, the tranfparent covering of the vitreous humour of the eye. See EYE.

MEMBRANA *Mucofa*, the febaceous fubftance covering the membrana tympani in the fœtus. See EAR.

MEMBRANA *Nictitans*, a peculiar fold of the conjunctiva, which can be drawn acrofs the front of the eye by means of two peculiar mufcles connected with it. (See BIRDS, *Anatomy of*.) In quadrupeds a piece of cartilage is placed in a fold or the fame kind, and the eye can be rolled behind it. See MAMMALIA, *Anatomy of*.

MEMBRANA *Pituitaria*, the mucous membrane lining the cavities of the nofe. See NOSE.

MEMBRANA *Pupillaris*, an exceedingly thin production filling the aperture of the pupil in the fœtus. See EYE.

MEMBRANA *Ruyfchiana*, the internal furface of the choroid membrane of the eye. See EYE.

MEMBRANA *Tympani*, a membrane terminating the meatus auditorius externus, and forming the boundary between it and the cavity of the tympanum. See EAR.

MEMBRANE is a term applied to feveral parts of the body, which confift of thin fheets of animal fubftance, in which the thicknefs bears a very fmall proportion to the furface. This difpofition is found in feveral tiffues; the term, therefore, denotes a peculiarity of arrangement and form, and not of internal ftructure, and hence it includes parts differing from each other very widely in organifation, properties, and functions.

Membranes never have an infulated exiftence: they are diffeminated among the other organs of the body, and concur in their formation; hence their hiftory has generally been affociated to that of the organs on which they are expanded. This is a convenient arrangement for purpofes of defcription, but it occafions us to lofe fight of the analogies between the particular membranes, and to neglect thofe general confiderations, which form a very interefting part of the ftudy of anatomy, which exhibit to us nature every where uniform in her proceedings, varying only in their refults, fparing of the means which fhe employs, profufe in the effects obtained from them, modifying in a thoufand ways fome general principles, which, differently applied, prefide over the animal economy, and are the fources of its innumerable phenomena. Haller has fome general remarks on the membranes, but he eftablifhes no demarcations between them. He defcribes them all as analogous in their texture, and having for their common bafis the cellular organ, to which he fays that they may all be eafily reduced, principally by means of maceration. That this view is incorrect in many points, will appear from the fequel of the prefent article: how, indeed, can we expect the compofition to be the fame, when the conformation, the vital properties, and the functions are different?

Bichat is the anatomift to whom we are the moft indebted for an elucidation of this fubject. His "Traité des Membranes en general, et des diverfes Membranes en particulier," Paris, an 8, contains a diftribution of thefe organs into certain claffes, a general account of each of thefe, and a particular defcription of the individual membrane. "When," fays he, "we obferve all the membranes in a general view, it feems that their claffification muft be very complicated, both on account of their great number, and their apparent variety. The extent of the different membranes, compared to that of the fkin, cannot be lefs than in the proportion of eight to one: yet, perhaps, no two of them exactly agree in appearance. An examination of their ftructure and functions quickly fhews us that feveral come near to each other, and are diftinguifhed only by their form." Bichat eftablifhes two general divifions, *viz.* the fimple and compound membranes: the latter are compofed of two of the former united together, and exhibit a combination of the characters of each. He makes three claffes of fimple membranes. 1. The mucous, fo named from the fluid which moiftens their furface. 2. The ferous, characterifed alfo by the particular fluid which covers them, and containing the membranes that line the feveral circumfcribed cavities connected with the different vifcera, and the fmooth coverings of the joints, burfæ mucofæ, &c. 3. The fibrous, moiftened by no fluid, and diftinguifhed by the fibres that enter into their compofition.

From the union of thefe proceed the fibro-ferous, fero-mucous, and fibro-mucous membranes.

There are moreover fome, which either exift infulated, or are little known, and confequently cannot be brought under any claffification.

The mucous membranes occupy the interior of the cavities, which communicate with the fkin at the various openings of the latter on the furface of the body. Their number appears confiderable on the firft view of the fubject; for the organs which they line are very numerous. The mouth, ftomach, inteftines, œfophagus, bladder, urethra, uterus, the ureters, all the excretory tubes, &c. &c. derive a part of their texture from thefe membranes. However, when we confider that they are every where continuous, that they arife by prolongations, one from the other, as we fee them originally derived from the fkin, their number muft be very much reduced. In fact, when we regard them thus in a general view, as expanded over all the organs in which they are continuous, and not as infulated in each particular organ, they are reduced to two general furfaces, which may be named, from the various parts over which they are extended, the gaftro-pulmonary, and the genito-urinary. The former is found in the head, neck, and abdomen: the latter in the abdomen, and more particularly in the pelvis.

There is one fmall infulated mucous furface, *viz.* that which enters the openings on the nipple, and lines the lactiferous ducts. As the obfervations on the others are applicable to this, we fhall not examine it in detail.

The gaftro-pulmonary furface enters the body by the mouth, the nofe, and the front of the eye. 1. It lines the two firft mentioned cavities, is continued from one of them into the excretory tubes of the parotid and fubmaxillary glands, and from the other into all the finufes of the nofe; it forms the conjunctiva, enters the puncta lacrymalia, lines the lacrymal fac and nafal duct, from which it is continued into the nofe. 2. It defcends into the pharynx, and penetrates through the Euftachian tube into the ear. 3. It goes into the larynx and trachea, and is expanded over all the air-tubes and veficles of the lungs. 4. It lines the œfophagus and ftomach. 5. It enters the duodenum, and furnifhes two prolongations, one to the ductus choledochus, the hepatic duct and its numerous ramifications, the cyftic duct and gall-bladder, the other to the pancreatic duct and its branches. 6. It is then continued into the fmall and large inteftines, and laftly ends at the anus, where it is identified with the fkin.

The fecond general mucous furface enters, in the male fubject, at the urethra, and thence is expanded, on one fide, over the bladder, ureters, pelvifes, and calyces of the kidnies, the papillæ of the fame organs and capillary tubes which open on their points; on the other it enters the excretory ducts of the proftate, the feminal orejaculatory tubes,

veficulæ

veficulæ feminales, vafa deferentia, and the numerous intricate ducts which arife from them. In the female this membrane enters at the colon, extends over the urinary organs as in man, penetrates the vagina, and lines that canal as well as the uterus and the Fallopian tubes, at the apertures of which it is continuous with the peritoneum. This is the only example in the animal economy of a communication between mucous and ferous furfaces.

The phrafes of membranes entering cavities, being prolonged or extended from one part to another, &c. are not to be underftood as indicating the progrefs of nature in the formation of parts, but merely as defcriptive of the relations exifting between the organs when fully formed. The membranes belonging to every part are formed independently in it, and not derived from any other.

The diftinction of the two great divifions of the mucous fyftem, and the connection of all the parts in each fyftem are manifefted, not only by anatomical refearches, but alfo by pathological phenomena. In epidemic catarrhs one of thefe furfaces is often affected throughout, while the other efcapes entirely; the gaftro-pulmonary membrane is the feat of the difeafe in all its divifions, and the genito-urinary is completely unconcerned in the affection.

Irritation of any point often caufes pain in fome other part of the fame furface; thus ftone in the bladder produces uneafinefs at the front end of the urethra, worms in the inteftines caufe itching of the nofe, &c. But it is very uncommon for partial irritation of one membrane to affect the other: yet there are examples of fuch an occurrence, as in the bleeding from the lungs, which frequently fupplies the place of menftruation, when it is interrupted accidentally.

The two mucous furfaces are united by means of the fkin: the latter organ with the former may be regarded as a general and continuous membrane, covering the exterior furface of the body at all points, and prolonged in the interior over moft of the important organs. Every mucous membrane has two furfaces; the one adhering to the neighbouring parts, the other free, in many cafes villous, and always moiftened with a mucous fluid.

The adhering furface correfponds almoft univerfally to mufcles, either of the animal or the organic life. The mouth, the pharynx, the whole alimentary canal, the bladder, a part of the urethra, &c. prefent a mufcular ftratum embracing the mucous membrane on the outfide. This difpofition agrees entirely with that of the fkin in animals which have a panniculus carnofus: there are indeed many points of refemblance between thefe organs, which we have already obferved to be continuous. It fubjects the mucous membranes to habitual motions, which probably favour the fecretion of their fluid and its fubfequent excretion, as well as the various other functions of thefe organs. The mufcular ftratum is inferted into the clofe and denfe tiffue, named by Bichat the tiffu foumuqueux, in which the ftrength of the organ refides, and which according to him decides and maintains the form of the part.

The free furface of the mucous membranes, habitually moiftened by the fluid, from which their name is derived, prefents three kinds of folds.

1. The firft are compofed by the mufcular as well as the mucous coat; their fituation is defined by a depreffion on the exterior furface of the organ, and they exift conftantly whatever may be its ftate in refpect to contraction or dilatation. The pylorus and valve of the colon are of this kind.

2. Others are formed in the mucous membrane only, are conftantly feen, whether the part be full or empty, but are rather lefs fenfible in the latter ftate. They arife from the membrane being much more extenfive than the furfaces to which it is applied, and being folded, compenfate this difference. The valvulæ conniventes of the fmall inteftine exemplify thefe very well. The cut edges of the mufcular and ferous coverings, as feen in a longitudinal fection of the inteftine, form ftraight lines, while that of the mucous furface is a very waving line.

3. The laft kind may be regarded in a manner as accidental, and is feen only when the organ is contracted; fuch are thofe of the ftomach and large inteftines. The cavity of the former, in particular, prefents, in this ftate, very numerous and large folds, which may be compared, in fome meafure, fo far as their appearance goes, to the cerebral convolutions. Diftend it fully, and the furface becomes completely fmooth. The exhauftion of the vital forces in individuals who die after lingering and debilitating difeafes, occafions their ftomachs to be frequently deftitute of thefe folds, although they may be empty. But if the full ftomach be cut longitudinally in a living animal, or in one recently killed, the contraction of the mufcular coat will fpeedily produce the folds in a very marked degree. It follows from this circumftance, that the furface of the mucous membranes is nearly as extenfive in the contracted as in the dilated ftate of the organs which they line. But all parts are not alike in this refpect; the obfervation is true of the œfophagus, ftomach, and large inteftine; but it is not equally applicable to the urinary and gall-bladders.

The free furface of the mucous membrane is every where in contact with bodies heterogeneous to that of the animal; which are either introduced from without for various purpofes, as in the alimentary canal and trachea, or derived from within, as in the excretory tubes of glands, all of which open on cavities lined by mucous membranes. Hence thefe membranes may be regarded as a kind of barriers, placed between our organs and extraneous fubftances, and protecting them from the noxious impreffions of the latter, and ferving the fame purpofe in the interior of the body, which the fkin fulfils on the outfide with regard to the objects that furround us, and are inceffantly acting upon us.

The organifation and vital properties of the mucous fyftem are accommodated to this habitual contact with foreign fubftances. Solid matters, as metals, ftone, wood, &c. introduced into the interior of other parts, inevitably excite inflammation and fuppuration by their fimple contact; but they traverfe the mucous fyftem with impunity, provided their angles or afperities do not tear it; various things for example go through the alimentary canal, and are voided per anum, without having excited an uneafy feeling. Irritating fluids may be fwallowed, or injected per anum, although they would produce abfceffes, if conveyed into the cellular fyftem.

On the other hand, this fyftem may be expofed with impunity to external agents, where any part of it is protruded either through the natural, or through artificial apertures. This is exemplified in prolapfus of the uterus and rectum, of the inteftine through an artificial anus, &c. In thefe inftances the mucous furfaces feem to ferve the office of integuments, and furrounding bodies hardly affect them more than they do the fkin. The ferous fyftem, on the contrary, when expofed, as in the operation of hernia, &c. inevitably inflames. The cellular, mufcular, nervous, and glandular tiffues exhibit the fame phenomenon.

Fiftulous openings are every where furrounded by a callous fubftance, which defends the cellular and mufcular tiffues traverfed by the fiftula: an expofed mucous furface exhibits nothing of this kind, becaufe its organifation fufficiently protects

protects it. The urinary and other fluids never escape through artificial canals excavated in the surrounding organs, without callosities being formed in the course of these canals; on the contrary, they traverse mucous surfaces with impunity. Cut an opening in a limb, and leave a tube in it; a callous canal will be formed round that tube. Leave a catheter in the urethra, and no alteration of structure is produced. "Let us conclude," says Bichat, "from all these considerations, that the mucous and cutaneous systems only are so organised as to support the contact of foreign bodies without being affected by their presence, or at least without feeling any further effect than an augmentation of secretion, which is not at all dangerous. These two systems then form two limits, an internal and an external one, between which are placed the organs, whose structure, or peculiar sensibility, incapacitates them from bearing the contact of extraneous bodies. The influence of the excitation produced by such bodies reaches no farther than these boundaries; the other organs feel nothing of it. We may conceive that the acute sensibility possessed by these systems acts as a kind of centinel, placed by nature at the confines of the organic domain of the soul, to warn it of the approach of every thing hurtful."

There are two points to be considered in the organisation of the proper tissue of the mucous system; *viz.* a more or less thick stratum making up its chief bulk, and which, from its analogy to the corion of the skin, may be called the mucous corion; and a number of small prominences surmounting the latter, and called villi or papillæ. The epidermis is considered with that of the skin, under the article INTEGUMENTS. It does not agree in any respect with the colouring substance of the skin, which is placed between the papillæ and the epidermis. In fact, we know that in the black, as well as in the white races, this tissue is of a bright red, derived from the blood-vessels.

Mucous Corion.—This important part of the mucous tissue, which regulates the thickness, form, and very nature of the organ, has a soft and spongy appearance; it appears at the first view like a thick pulp, covering the dense cellular tissue which lies under it. Its softness distinguishes it from the cutaneous corion, which indeed resembles it but little in its intimate nature. Its thickness varies very considerably; in the gums and palate it is thickest, and decreases successively in the following organs, *viz.* the nose and stomach, small intestine and gall-bladder, large intestine, urinary bladder, urethra, and the various excretory tubes. When cautiously removed in the latter, it appears transparent, like a serous membrane. It is thinnest in the sinuses of the head, and the cavity of the ear. The lining of the latter has been generally called periosteum by anatomists; but its continuity with the pituitary membrane through the Eustachian tube, the mucous fluid that habitually covers it, and every circumstance that we can observe of its appearance and texture, shew that it belongs to the mucous system; and its diseases agree with those of that system. Diseases produce great changes in its thickness; and distention or contraction of the organs to which it belongs have analogous effects. The degree of softness which it exhibits, is very different in different situations. In the nose, stomach, and intestines, it is like velvet, and the name of villous coat characterises it very well. At the origins of the system, as the mouth, nose, glans penis, &c. it is much more dense, so as to approximate in its nature to the cutaneous corion. In the latter situations it is the seat of variolous pustules, which are often seen on the tongue, palate, and cheeks, but never on the internal mucous surfaces. It becomes dry and very thin by exposure to the air, but preserves a certain degree of resistance. The muscular and serous coats of an intestine are pliable when dried, while the mucous covering is rigid. It is transparent after desiccation, in organs where it is naturally pale, as in the rectum and bladder; it exhibits a darker tint in parts where it is redder, as in the stomach, and has even a blackish cast when much blood is accumulated in it by preceding inflammation. It putrifies with great facility, and acquires a very fetid odour: this is one reason why the abdomen of a dead body passes so soon into the putrid state. In this change it acquires a greyish colour, and as the subjacent cellular tissue decays much more slowly, it may be removed by very slight pressure in the form of a disorganised and fetid pulp. Gangrene attacks it much less frequently than the cutaneous tissue; yet it occurs sometimes, as in putrid sore throat. It yields very speedily to maceration; quicker indeed than any organ, except the brain. It is converted into a reddish pulp, very different from that produced by putrefaction in the open air. Ebullition extracts from it a greenish froth, very different from that produced by the muscular and cellular tissues. Before the water begins to boil, it curls up, but in a less degree than other structures. In fact the tissu soumuqueux then contracts much more than it, so as to throw it into a recurved state. In the same way, the contraction of the serous and muscular strata of the stomach during life, being much greater than that of the mucous, produces the numerous folds of the latter. A concentrated acid has the same effect. After having been dried for a long time, it still is curled up when plunged into boiling water. The valvulæ conniventes of the intestine, which disappear on drying, are then reproduced. Long ebullition brings it to a dark grey colour; it is not rendered softer, but may be more easily torn. In this respect it is contrasted with the subjacent cellular stratum, which preserves its power of resistance much longer. It never has the gelatinous appearance, which the cutaneous corion, the fibrous organs, cartilages, and other structures which afford much gelatine, present on boiling. The action of acids reduces it into a pulp much more quickly than any other tissues. Caustics act on it more rapidly than on the skin, where the epidermis protects the corion. Nitric acid, taken into the alimentary canal, produces a whitish scar on the mucous surface, which, when death does not follow suddenly, is gradually detached in the form of a membrane. All mucous surfaces, and particularly those of the stomach and intestines, have the power of coagulating milk. That of the former still possesses this power after desiccation.

Mucous Papillæ.—The peculiar mode of sensibility enjoyed by the skin is usually ascribed to its papillary structure, which is not very readily demonstrable. The sensibility of mucous membranes, analogous, in many respects, to that of the skin, arises probably from the same kind of texture, which is here more readily discerned. The existence of papillæ cannot be doubted at the origins of the system, and at the commencement of the cavities, as on the tongue, the palate, the alæ nasi, glans penis, &c. The villosities with which the internal surfaces are every where covered, must be regarded as an analogous organisation; and the existence of an analogous sensibility on these surfaces strengthens the opinion. A very different function has generally been assigned to these villi; they have been regarded in the alimentary canal, as destined to the exhalation of various fluids, the absorption of chyle, &c. Bichat considers it incorrect to ascribe to an organ so similar in all parts such a diversity of offices. He considers that the microscopical observations, on which is grounded the opinion that the villi absorb the chyle, do not deserve much confidence, as different observers give such different reports. And he cannot account for

for the villi of the pituitary membrane, urethra and bladder, unless on the supposition of their being connected with the sensibility of the parts. The delicacy of the objects renders their structure so obscure, and their investigation so difficult, that the question can hardly be decided by direct observation. Analogy and observation of the vital properties must guide us in forming an opinion.

The papillæ exhibit very numerous varieties; they are remarkably long on the tongue, small intestine, stomach, and gall-bladder; less distinct in the œsophagus, large intestine, urinary bladder, and the excretory tubes; the latter, in fact, are almost completely smooth on their mucous surfaces.

Besides blood-vessels, exhalants, and absorbents, which enter into the structure of this system, as into that of all others, it presents another common organ of a glandular nature, which is generally insulated, but here forms part of the system. The mucous glands probably exist throughout the system. Situated under the corion, or in its substance, they constantly pour out a mucilaginous fluid, which lubricates the free surface of the membrane, protecting it from the action of the bodies that come in contact with it, and facilitating their passage. They are very apparent in the trachea and bronchi, the œsophagus and intestines; they cannot be shewn in the urinary and gall-bladders, the uterus, the vesiculæ seminales, &c.: their existence in these organs can therefore only be inferred from the circumstance of a mucous fluid being produced analogous to what is found where the glands are manifest.

If we admit the force of this reasoning, and allow that identity of the secreted fluid proves identity of the secreting organ, we shall establish as a striking difference between the mucous and serous membranes, that the fluid of the former is produced by secretion, that of the latter by exhalation. Their size varies in different organs; they are largest in the lips, cheeks and palate. They generally have a rounded form, are dense in their texture, and surrounded by cellular substance, but contain very little of that substance in their interior. Little or nothing is known of their diseases. For further particulars, see GLAND.

A difficulty occurs in ascertaining the composition of mucous fluids, because they are formed in very small quantity in health, and are probably changed in their composition when increased in quantity in disease. They are generally insipid, colourless, and tenacious; but their colour, viscidity, and odour, differ in different organs. For a further chemical account of them, see MUCUS.

Their use in the animal economy is obvious: they protect the mucous surfaces from the impressions of those heterogeneous substances, with which they are all in contact, by forming a stratum, which compensates for the extreme thinness or even the entire absence of epidermis. Hence they are more abundant where foreign matters lodge for some time, as in the alimentary canal, than where they only pass occasionally, as in the excretory tubes. For the same reason, they are poured out more abundantly where any foreign body of an unusual kind is left permanently in contact with a mucous surface, as a catheter in the urethra, a tube in the trachea, &c. In all these cases the effect must be referred to an irritation of the excretory orifices; for the body does not come in contact with the glands themselves.

By the secretion continually going on in the mucous membranes, they perform another important part in the animal economy. They are one of the great emunctories, by which the residue of nutrition is carried off, and, consequently, one of the principal agents in that habitual decomposition, which the solids of the living body are constantly undergoing. All the mucous fluids are rejected from the body; that of the ureters, bladder, and urethra, with the urine; that of the alimentary canal with the feces, which are often very copious when nothing is taken in by the mouth; &c. If we consider that the two mucous surfaces, taken together, are of equal, if not greater extent than the skin, we shall deem their functions very important in this point of view. When these fluids have remained for some time in rather considerable quantity on their respective surfaces, a disagreeable sensation is produced, and leads to their expulsion in various ways. The air-passages are cleared by coughing; the stomach by vomiting, &c. Mucous membranes possess a great number of blood-vessels, and are hence distinguished by a remarkable redness, which however is not an uniform character. In the sinuses of the head, and the internal ear, they are whitish, and appear the more so, because their extreme thinness allows us to discern the bone, on which they are applied. In the bladder, the large intestine, and the excretory tubes, the colour is deeper, but still pale. In the stomach, small intestine, vagina, pituitary membrane, and mouth, the redness is strongly marked. It arises from a vascular network, the branches of which, after being ramified in the mucous corion, are expanded in a state of very minute division on the mucous surface. Their unsupported position makes them liable to rupture on the application of any force, as in the bronchi from coughing, in the ear and nose from blows on the head, &c. The passage of stones will produce bleeding from the ureters or bladder, and that of catheters from the urethra.

The superficial situation of these vessels enables us to judge by them of the state of the circulation; hence the lividity of the lips, nose, &c. in asphyxia.

Whether the quantity of blood in the mucous membranes be constantly the same, and particularly whether it varies in those organs, which are seen in very different states of contraction and dilatation, as the alimentary canal, are points concerning which we possess hitherto no means of judging.

The number of blood-vessels belonging to the mucous system, the fact that the blood is changed in respiration by exposure to the air through its containing vessels, and that it will also become red when placed in a bladder immersed in oxygen, led to an inquiry whether any change is produced by the air in the blood of mucous surfaces. Bichat could not discern any alteration from enclosing oxygen gas in a portion of intestine, or from making it pass backwards and forwards through a part of the canal.

This author conceives, that the red colour of the mucous is analogous to that of the muscular system, and derived from the colouring matter of the blood combined with the tissue of the part; except at the origins of these surfaces, where the cause of colour is principally in the blood contained in the vessels. Asphyxia does not affect the deeply-seated parts, so much as those which are superficial, and communicate with the skin; the latter become suddenly white in syncope, where the heart sends no more blood into the arteries. Repeated washings take away the red colour; and sudden whiteness is produced by immersion in boiling water or in acids. It is, on the contrary, increased to a remarkable degree of intensity in inflammations, on account of the increased quantity of blood accumulated in the capillary system.

It is a question, whether exhalation takes place on mucous surfaces: the analogy of the skin seems to indicate that it does. The pulmonary vapour, which is best seen when condensed by cold air, has been generally referred to the exhalants of the air-paſſages; the gaſtric fluid, and fluid of the inteſtines, has been aſcribed to the ſame ſource. It ſeems difficult to arrive at any certainty on ſuch a point.

There is a great tendency in the exhalant veſſels of the mucous organs to allow the paſſage of blood; hemorrhages without rupture are very frequent in them.

That abſorption is carried on from mucous ſurfaces is proved by numerous familiar phenomena; *viz.* by the chyle and fluids taken up from the ſtomach and inteſtines; by the vapour of turpentine from the lungs; by the removal of the aqueous portions of the bile and urine, &c. This abſorption is by no means conſtant and uninterrupted, as in the ſerous membranes; it exhibits numerous varieties according to the ſtate of the vital powers of the part.

The origins of the mucous ſyſtem, where the animal ſenſibility is clearly marked, and ſerves, as in the ſkin, to eſtabliſh our relations with external bodies, poſſeſs cerebral nerves. In the pituitary and palatine membranes, the conjunctiva, the rectum, glans, prepuce, &c. this fact is evident; hardly any nervous twigs from the ganglia are ſeen in theſe ſituations. The latter, on the contrary, predominate in the inteſtines, the excretory tubes, the reſervoirs of ſecreted fluids, &c. where the organic ſenſibility is more marked.

Properties of the Mucous Syſtem.—The extenſibility and contractility of tiſſue are much leſs extenſive in this ſyſtem than they would appear to be on the firſt view, on account of the numerous folds which it preſents in the hollow organs, when they are contracted. Yet theſe properties are very apparent under certain circumſtances; the excretory tubes are often diſtended much beyond their natural ſize; the ureters ſometimes are almoſt as large as an inteſtine, and the ductus choledochus and the pancreatic duct exhibit ſimilar enlargements. The urethra and ſalivary ducts, on the contrary, do not readily yield to diſtention.

Theſe properties are called into action very rapidly in the mucous ſyſtem; the ſtomach, inteſtines, bladder, &c. paſs in a moment from a dilated to a contracted ſtate.

When mucous canals are no longer traverſed by the fluids which are habitual to them, they remain permanently contracted, but are not obliterated on account of the preſence of their mucous ſecretions. This fact may be obſerved in the inteſtinal canal in the caſe of artificial anus, in the urethra when the urine has run for a long time through the wound made in lithotomy, &c. Neither do they contract adheſions under inflammation, as is the caſe in ſerous cavities, and in the cellular tiſſue. The importance of this circumſtance to the great functions of life is very obvious: the mucous cavities would be rendered uſeleſs if they were ſubject to the frequent adheſions which we obſerve in pleuriſy, peritonitis, &c.

Vital Properties. 1. *Properties of the Animal Life.*—Like the integuments, mucous ſurfaces are conſtantly in contact with external bodies, and therefore require a ſenſibility, which may enable the mind to perceive the relations between us and thoſe bodies, particularly at the origin of the ſurfaces. Hence the animal ſenſibility exiſts there in a very marked degree. In many places it is even ſuperior to that of the ſkin, which poſſeſſes no feeling ſo lively as thoſe produced by odours on the pituitary membrane, by ſavours on that of the mouth, on the vagina, urethra, and glans, at the moment of coition, &c. This ſenſibility, like that of the ſkin, is ſubject to the powerful influence of habit, which conſtantly tends to render our ſenſations leſs lively, and brings to a ſtate of indifference the pleaſure and pain which they produce. A catheter left in the urethra, produces at firſt great pain; it becomes leſs and leſs troubleſome, and is at laſt hardly felt. Peſſaries in the vagina, tents in the rectum and other ſituations, &c. are further proofs of this fact. On this obſervation is grounded the poſſibility of keeping tubes in the trachea and œſophagus, for carrying on the functions of reſpiration and deglutition. This remarkable influence of habit is exerted only with reſpect to ſenſations produced by ſimple contact, and not ſuch as are cauſed by actual injury, as cutting, tearing, &c.; hence it does not make the bladder leſs ſenſible to the excruciating pain of the ſtone, the noſe to a polypus, or the trachea to a foreign body accidentally introduced. To this effect of habit we may probably refer in part the gradual diminution of the functions of the mucous ſyſtem in old age. The active ſenſibility of the alimentary, biliary, urinary ſurfaces, &c. in the young ſubject, is the chief cauſe why the digeſtive and ſecretory phenomena ſucceed each other ſo rapidly: the ſame phenomena take place more ſlowly in an old perſon, from the ſenſibility being rendered more obtuſe by the habit of contact.

The animal ſenſibility, which is acute at the origins of the mucous ſurfaces, as in the mouth, noſe, glans penis, opening of the rectum, &c. is leſs marked in the more deeply-ſeated organs. In the former parts we always perceive the bodies that come in contact, but there is no ſuch perception in the latter. Does this ariſe from the uniformity of the impreſſion in the latter caſe affording no term of compariſon? For each of theſe organs is brought into contact with one kind of ſubſtance only, while the others are expoſed to a variety of excitations. In fact we perceive impreſſions made on the deeply-ſeated organs, when they are brought into contact with extraneous bodies; as when a catheter is introduced into the bladder, &c.

The ſenſibility of the mucous ſyſtem is much increaſed in diſeaſe; acute catarrhs are very painful. We not only perceive the contact of bodies then, but find it very diſtreſſing. Yet the ſenſibility in theſe caſes never riſes to the point which it reaches in inflammations of the cellular, ſerous, fibrous, and other tiſſues.

The mucous ſyſtem exhibits no animal contractility.

Properties of the Organic Life.—The organic ſenſibility and the inſenſible contractility are ſtrongly marked in the mucous ſyſtem. They are called into action by four different cauſes: 1, by the nutrition of the ſyſtem; 2, by the abſorption, which either takes place naturally, or accidentally; 3, by the exhalation; 4, by the continual ſecretion of the glands. Theſe two properties are the primary cauſes of all theſe functions, the augmentation or diminution of which indicate their degree of activity. As numerous cauſes are conſtantly acting on the mucous ſurfaces, particularly at their origins, this degree is very frequently changing, as well as the functions which reſult from it.

The mucous ſyſtem then differs from moſt others, in having its organic properties habitually more active, on account of the more numerous functions, over which they preſide; and in having them change ſo frequently from variations in the excitation applied to them. In the bony, fibrous, cartilaginous, muſcular, nervous, and other ſyſtems, theſe properties are only called into exerciſe by nutrition; and, on the other hand, no excitation can be applied to them; ſo that the properties remain permanently at the ſame degree.

From the preceding view, we cannot be ſurpriſed that the diſeaſes, which particularly put in action the organic ſenſibility, and the inſenſible contractility, ſhould be ſo frequent in the mucous organs. All the catarrhal affections, whether

whether acute or chronic, the hæmorrhages, the various tumours, polypi, funguſes, &c. all kinds of excoriation, ulcers, &c., which are ſeen in theſe organs, ariſe from the various alterations of which the organic properties are ſuſceptible.

The mucous ſyſtem does not ſeem to poſſeſs the ſenſible organic contractility; yet it ſometimes exhibits phenomena, which ſeem to indicate ſomething more than the inſenſible oſcillations which compoſe the inſenſible organic contractility. The parotid duct ſometimes throws out its contents to ſome diſtance from the mouth, although it ſeems entirely of a mucous ſtructure, and has no muſcular agent of impulſion at its origin. Perhaps the excretory ducts of the glands, which open on the deeply-ſeated mucous ſurfaces, exhibit the ſame phenomenon, which has been obſerved in ſome degree in the lactiferous tubes. Theſe motions, analogous to thoſe of the dartos, the cellular tiſſue, &c. ſeem to hold a middle place between thoſe of tonicity and irritability.

The ſympathies of the mucous ſyſtem are very numerous.

Active Sympathies.—When any part of this ſyſtem is inflamed or irritated in any manner, all the vital powers may be ſeparately called into action in other ſyſtems. Sometimes the animal contractility is exerted; thus the muſcles of reſpiration produce ſneezing or cough, when the pituitary or bronchial membrane is irritated; or even when the ſurface of the ſtomach is affected. A general ſpaſm is obſerved, when a foreign body lodges about the glottis. Stone in the bladder cauſes contraction of the cremaſter. In other caſes the animal ſenſibility is excited by affections of the mucous ſurfaces. Stone in the bladder produces itching of the glans penis. And a ſimilar effect is produced in the noſe by worms in the inteſtines.

The ſenſible organic contractility may be ſympathetically excited by affections of the mucous ſyſtem. The organic muſcles generally contract from the excitation of a contiguous mucous ſurface. A ſtone in the pelvis of the kidney, or irritation of the uvula, produces vomiting. The action of the heart is accelerated when the ſeminal fluid is paſſing over the urethra.

Sympathy of the organic ſenſibility is exemplified in the furred tongue, connected with the affections of the ſtomach, in the hæmorrhages which ſupply the place of ſuppreſſed menſtruation, in the diminution of the cutaneous tranſpiration obſerved by Sanctorius at the time of digeſtion, &c.

Paſſive Sympathies.—In various diſeaſes, a ſenſation of burning heat is felt in the mouth, ſtomach, and inteſtines, although theſe parts do not ſeem to be actually hotter than is natural.

Cold bodies applied to the neighbouring ſkin ſtop bleeding from the noſe and uterus. Moſt catarrhs ſeem to be produced by the action of cold on the ſkin. A cold atmoſphere confines the functions of the ſkin, and occaſions thoſe of the mucous ſyſtem to be proportionally extended. The pulmonary exhalation is more ſtrongly marked, the internal ſecretions more abundant, digeſtion more rapid, and the appetite conſequently more eaſily excited. In warm ſeaſons and weather, on the contrary, the ſkin acts more powerfully, the ſecretions, particularly of the urine, are diminiſhed, the digeſtive phenomena proceed ſlowly, and the appetite is recovered more difficultly. In ſcarlet fever the throat is remarkably affected. In the laſt ſtages of organic diſeaſes of the viſcera, as of the lungs, heart, liver, in cancers of the uterus, &c. the mucous membranes are uſually affected: hence the colliquative diarrhœas ſo common in theſe caſes.

Character of the Vital Properties.—In this ſyſtem, as in the ſkin, the vital properties are almoſt permanently in action, as it is conſtantly in contact with ſubſtances that affect it in ſome way or other. But they are not the ſame in all parts: they undergo, in each, particular modifications, ariſing probably from the differences of ſtructure already pointed out, in the nature of the corion, the diſpoſition of the papillæ, the diſtribution of the veſſels and nerves, of the glands, &c. We ſee how widely the animal ſenſibility of the pituitary membrane differs from that of the mouth, how the urethra and glans are affected by the paſſage of the ſeminal fluid, which would make no impreſſion on any other mucous ſurface. Each part bears a certain relation to the fluid which habitually covers it, and could not bear the contact of others without pain. The urine would excite the ſtomach, and the gaſtric juice the bladder; the bile, which remains quietly in the gall-bladder, would irritate the pituitary membrane, or veſiculæ ſeminales.

From theſe varieties in the vital powers of the different diviſions of the mucous ſyſtem, we naturally derive the differences obſerved in the diſeaſes affecting this ſyſtem. To the ſame cauſe we muſt alſo refer the differences of the ſympathies. Each part has a peculiar ſympathetic action on other organs. Irritation of the pituitary membrane alone cauſes ſneezing: that of the fauces, vomiting, &c.

Developement of the Mucous Syſtem.—It is proportional, in general, to that of the organs to which it belongs, and is, therefore, earlier in the gaſtric apparatus, later in the pulmonary organs, and ſtill more ſo in thoſe of generation. The tiſſue is very delicate, and the papillæ hardly ſenſible in the fœtus. Its redneſs is not ſo clearly marked: leſs blood penetrates it, becauſe the functions, of which it will at a future time be the ſeat, are either exerted feebly, or have not yet commenced. At this time the cutaneous ſyſtem is in the oppoſite ſtate with reſpect to the quantity of its blood. The mucous ſurfaces are often livid from the nature of the blood contained in their arteries. Its adheſions to the ſurrounding parts are weaker: hence it may be drawn out of the inteſtines in an entire piece.

At the time of birth reſpiration and digeſtion begin ſuddenly, and the ſecretions are increaſed: hence the mucous ſyſtem exhibits a remarkable degree of activity. New ſubſtances come in contact with it, and ſtimulate it: red blood enters its veſſels, augments its energy and ſenſibility, and renders it more fit to receive impreſſions. When the internal functions are once eſtabliſhed in a ſtate of activity, the mucous ſurfaces exhibit no further ſudden changes. They act with conſiderable energy during the time of youth. Active hæmorrhages are frequent, as thoſe of the noſe, air-paſſages, and even of the ſtomach: yet, in general, they are not frequent in the organs below the diaphragm. They are much more common in men in the gaſtro-pulmonary, than in the genito-urinary ſurface: in women, on the contrary, who have a natural evacuation of blood from one part of the latter ſurface, they are moſt frequent in it: at the epocha of puberty, the developement of the organs of generation in both ſexes gives an increaſed activity to one part of the genito-urinary ſurface: but this is not accompanied with any debilitation of other parts, all of which, on the contrary, ſeem to acquire at this time a more energetic action. The mucous ſyſtem becomes thicker and firmer in the years ſubſequent to puberty. Its vital energy ſtill predominates for ſome time in the ſuperior ſurfaces; but, as age advances, this predominance, as well as that of other organs, is transferred to the abdomen.

Numerous cauſes change the ſtate of this ſyſtem during life. It will hardly be found to exhibit the ſame colour, denſity,

density, or external appearance in any two subjects. This may be seen in any particular surfaces, as that of the stomach for example.

The redness of the mucous system is clearly marked till the thirtieth year; beyond this time it changes. It receives less blood, grows more and more pale, and becomes more dense in the old subject. The remarkable soft and villous touch is no longer perceived. The vital powers grow languid; yet the mucous glands often separate their fluids abundantly, and even in increased quantity. Absorption takes place difficultly at this time from mucous surfaces, as from all others. The chyle is taken up more slowly; so that the digestion is longer, and contagious diseases are less readily taken.

The serous membranes consist of two kinds essentially distinct from each other. The first includes the pleura, pericardium, peritoneum, arachnoid, tunica vaginalis, and in general all the membranes of the great cavities. These are the proper *serous* membranes. The second comprehends the membranes that line the joints, and those which form the bursæ mucosæ, which may go by the common name of *synovial* membranes. These two kinds are joined in one class on account of their both possessing the external character of forming a bag without openings, of their being composed of cellular tissue, and being the seat of alternate exhalation and absorption. A strong line of demarcation is established by the different nature of the fluid that lubricates them, by the synovial membranes being exempted from the general dropsical affections of the serous, and of the cellular tissue, and *vice versâ*.

The serous membranes generally cover the outside of those organs which are lined by mucous membranes, as the stomach, intestines, bladders, lungs, &c.; and it surrounds all those which are essential to life, as the brain, heart, gastric viscera, &c.

It does not form, like the mucous system, a surface every where continuous over the numerous organs to which it belongs; but its different divisions are insulated, and these are rather numerous. When taken altogether they surpass in extent the mucous surfaces. The particular membranes vary considerably in their extent, from the peritoneum, which is the largest, to the tunica vaginalis, which is the smallest. When taken altogether, they would form a surface greater than that of the skin.

Every serous membrane represents a bag without an opening, extended over the various organs which it includes, which may be either very numerous, as in the peritoneum, or single, as in the pericardium. It covers the organs in such a manner that they are not contained in its cavity, and that, if it were possible to dissect it completely off from them, it would form a perfect bag. In this respect it may be compared to the double night-cap, of which the part immediately covering the head is analogous to the serous membrane investing an organ, and the portion in which this is included represents the lining of the cavity in which the organ is contained. From this description, it will be readily understood, that the serous membranes do not open to allow a passage to the vessels or nerves which arrive at, or depart from, their respective organs, but that they are always reflected over them, accompanying them to the organ, and forming a sheath round them. This arrangement prevents the serum, which lubricates the serous cavities, from gaining admission into the neighbouring cellular substance, which it would do with great facility, particularly in dropsies, if the serous membranes, like the fibrous, were perforated for the passage of vessels and nerves.

From the general idea which we have given of these membranes, it will be easily understood that each of them is composed of two parts, distinct although continuous; the one lining the internal surface of the cavity in which it is found, the other covering the organs belonging to the cavity. Thus, there is a pleura costalis and pulmonalis, a portion of peritoneum lining the abdominal parietes, and another covering the abdomial viscera, &c.

The fimbriated end of the Fallopian tube offers the only example of a continuity between a serous and a mucous surface.

In every serous membrane there is a free surface, contiguous with itself at all points, and another adhering to the surrounding parts. The former is remarkable for its perfect smoothness and polish, which distinguishes this system and the following from all other membranes. All the organs, which have this polished surface, owe it to a serous covering: many have such a covering only on some part of their surface, and are rough elsewhere, as the bladder and liver.

The free surfaces of the serous membranes completely insulate the parts, over which they are expanded, from the surrounding organs, so as to form a kind of boundaries or barriers, if that term may be employed. Hence the great viscera, confined by their serous coverings, and suspended in the bags which they form, communicate with the adjacent parts only at the points where their vessels enter: in all other situations there is contiguity, but not continuity with the surrounding organs. This insulation of position coincides with the separate vitality of the organs. Each has its peculiar life, resulting from the particular modification of its vital forces, which establishes corresponding peculiarities in its circulation, nutrition, &c. No part feels, moves, or is nourished like another, unless it belong to the same system: every organ displays, on a small scale, the phenomena which appear on a larger plan in the animal economy: each takes from the circulating fluid the matter which suits its nature, prepares this matter, returns to the mass of the blood what is heterogeneous to it, and appropriates what can furnish it with the right nourishment: this, in fact, is digestion. Hence it is an important use of the serous membranes to contribute to this independence of the vital powers and functions of the organs. In the same way the serous coverings insulate the morbid affections of a part.

The smoothness of the free surface of the serous system facilitates the motions of the organs which it covers: the cellular substance is the principal means by which the movements of external parts are provided for, while these membranes are particularly designed for the internal organs.

This surface differs essentially from the corresponding one of mucous membranes, in the circumstance of its very frequently contracting adhesions. The pleura is hardly free from them in any subject: the peritoneum comes next, then the pericardium, the tunica vaginalis, and, lastly, the arachnoid, in which they are the most uncommon. They are seen under various forms. 1. The costal and pulmonary pleuræ may be completely united so as to form apparently but one membrane. 2. They may be joined so loosely that very slight force is sufficient to detach them: the opposed surfaces, when detached, have lost their polish and smooth surface. 3. The two pleuræ may be united by longer or shorter bands, having the same organisation, and the same highly polished surface, as the membranes which they join together. 4. The adhesion may be of a flocculent nature, and resembling cellular substance. 5. Depositions of coagulating lymph may join the two membranes: but these are foreign to the surfaces.

The

The external surfaces of serous membranes adhere in almost all cases to the surrounding organs: in a few instances these membranes are insulated on both sides. Yet, although they adhere to their respective organs, their organisation is not connected with that of these parts. They sometimes, by turns, cover and leave uncovered the organ to which they belong: the broad ligaments of the uterus serve as a serous membrane to that viscus during pregnancy. The peritoneum lining an enormous hernial sac, has previously lined the abdomen. Since then the organs and the serous membranes can exist independently of each other, there is no reciprocal connection in their organisation. The medium of union is cellular tissue, and not a vascular apparatus. The membrane may be, and generally is, affected independently of the organ, and *vice versâ*: this is seen in the intestine in peritonitis and diarrhœa. Hence we may infer, that the organisation and the life of the serous membranes are entirely independent of the organs which they surround. Yet, in some cases, they are inseparably attached to the subjacent parts, as the tunica vaginalis to the albuginea, and the arachnoid to the dura mater.

The smooth surface of every serous membrane is moistened with a fluid very similar to the serum of the blood. It is constantly poured out by the exhalants, and removed by the absorbents. It is a simple moisture in the natural state, and is dissolved in the air, and rises in the form of vapour from serous surfaces exposed in living or recently killed animals. It is more abundant in the dead subject, as it is increased by the fluids transuding through the blood-vessels after death; and its augmentation during life causes dropsies of the various cavities. In the first stage of inflammation the serous exhalants produce no fluid: as they remain thus preternaturally dry, and are very sensible, motion is highly painful. At this time adhesions are formed. If the affection continue, suppuration ensues, but the membranes are never ulcerated. Their tissue is thickened, and pus is poured out by their exhalants. This fluid varies in consistence from a milky serum to a complete and thick stratum of coagulating lymph, which adheres to the surface from which it has been exhaled.

The fluids of the serous system are plainly of an albuminous nature. One of these membranes plunged into boiling water is covered with a whitish stratum of concreted albumen. This substance predominates in the fluid of dropsies. The flocculent matters, which often float in such fluids, the new membranes, and the white substance, which sometimes gives them a milky appearance, are merely albumen in various states of consistence.

Organisation of the Serous System.—It is characterised by a whitish shining colour, and a remarkable transparency: the thickness varies, but is never considerable in the natural state. It consists of a single layer, from the surface of which cellular strata may be removed, but which can never be divided into two or more portions. No pellicle is raised from it by the action of a blister.

The organic systems are formed, 1st, of common parts, as cellular membranes, blood-vessels, exhalants, absorbents, and nerves, which form the ground-work, or as it were the skeleton of the part; 2dly, of a peculiar substance deposited in this, as, for example, gelatine and phosphat of lime in the bones, fibrine in the muscles, &c. The organs, therefore, resemble each other in their common parts, and are distinguished by their peculiar tissues. The serous system seems to possess no peculiar tissue; it contains only the common parts. Cellular in its nature it differs from that system only in its form: the cells, instead of being separate and distinct, are here approximated and condensed. The continual exhalation and absorption of lymph belong to both these tissues, and the phenomena of dropsy are common to them both: this identity of functions and diseases leads us to infer an identity of nature. Maceration in water resolves these membranes into cellular tissue; and forcible inflation under them produces a somewhat analogous effect. Cysts, hydatids, &c. are formed in both. Nothing of a fibrous nature is observed in serous membranes, nor in the cellular tissue; although fibres of some kind characterise the other organs.

These proofs of analogy, or even of identity of structure between the cellular tissue and serous membranes, are corroborated by the effects of various reagents, which are exactly similar in both cases. A serous membrane dried becomes transparent, does not turn yellow like the fibrous membranes, still remains flexible, and gradually returns to its former state when immersed in water. It putrifies much more slowly than the parts which it covers, and resists maceration for a very long time, as may be seen in the delicate membrane of the omentum. It is curled up by boiling water like the fibrous system, but furnishes much less gelatine, and does not turn yellow. The ordinary chemical agents operate in the same way on both parts.

When it putrifies in the open air, it does not turn green like the skin, but becomes dull and of a deep grey. When it sloughs during life, it is black; in the latter case it contains much blood, and hence the source of its dark colour. The peritoneum is almost the only instance in which this gangrene occurs.

Yet there are circumstances of difference that distinguish the serous and cellular systems. Their external appearance is not the same. In the cellular tissue there is nothing analogous to the slow inflammation, accompanied with the production of small tubercles, which particularly characterises serous membranes, as miliary eruptions characterise the skin, and aphthæ the mucous surfaces. The pus formed by the cellular organ is not the same as the fluid produced by serous surfaces.

The exhaling vessels which produce the fluid just described are easily demonstrated. Withdraw an intestine from the abdomen of a living animal; you see no vessels in the serous surface, but it has a rose-coloured tint from those which lie under it. If you irritate it, return it into the abdomen, and draw it out again after some hours, it exhibits a number of reddish streaks, which are the exhalant vessels; these could not be seen in the natural state from the transparency of their contents. Minute injections have a similar effect on the serous membranes, and the injected fluid is often thrown out on the surface, probably from the exhaling orifices.

A large portion of absorbents enters into the composition of serous membranes, which may probably be regarded as an intertexture of these vessels and exhalants, united by cellular tissue. The mouths of these absorbents can no more be directly demonstrated than those of the exhaling vessels; but phenomena very clearly prove their existence. They are seen in the dead subject loaded with fluids taken up from the cavities to which they belong, as in the different dropsies, or in effusions of blood. Coloured fluids thrown into the serous cavities are said to be absorbed; but Bichat says that the colouring matter is not taken up. During life they often carry off very large watery effusions in a short time.

Serous membranes contain very few blood-vessels in their natural state; so few, indeed, that Bichat almost doubts their existence. Numerous trunks run in the cellular tissue of their external surfaces, but these may be removed by dissection, without injuring the membranes. In the omentum the

the exiſtence of blood-veſſels cannot be queſtioned; and in all caſes they muſt be connected to the membranes through the medium of the exhalants.

Although the ſerous ſyſtem is diſtinguiſhed by certain general characters, the particular membranes differ conſiderably: each has its peculiar ſtructure, ſuited to its ſituation and offices. The tranſparent arachnoid, yielding to the ſmalleſt force, is ſtrongly contraſted with the denſe and ſtrong peritoneum. Different parts of the ſame membrane are differently organiſed. The omentum is not like the reſt of the peritoneum; and the two portions of the tunica vaginalis are very different. Hence we ſhall not be ſurpriſed at finding great varieties in the diſeaſes of theſe membranes. Nothing is more common than inflammation of the pleura; that of the arachnoid is rare. The ſymptoms are different in inflammation of the pericardium, tunica vaginalis, and peritoneum; the dropſies are very different, &c. Yet there is a common character in the affections, ariſing from analogy of organiſation. The large ſerous collections, and the ſlow tubercular inflammation, belong eſpecially to theſe membranes: the mode of adheſion is peculiar to them.

Properties of the Serous Syſtem.

1. *Properties ariſing from Organiſation.*—The extenſibility and contractility of tiſſue are leſs extenſive in the ſerous membranes, than we might have ſuppoſed on the firſt view of the enormous dilatations which the organs covered by them occaſionally exhibit, and of the facility with which they recover their original ſize. The folds of the membranes, which are particularly marked near organs ſuſceptible of conſiderable variety in ſize, as in the abdomen, are ſeparated as the organs enlarge, and contribute to their covering. Yet a conſiderable extenſion takes place in many caſes, in the peritoneum in aſcites, in the tunica vaginalis in hydrocele. The contractility is proportional: thoſe membranes are reſtored to their original ſtate when the diſtending fluids are removed. After very long extenſion they do not recover completely: the tunica vaginalis is flaccid when emptied, and the peritoneum in old dropſies.

2. *Vital Properties.*—Removed by their ſituation from the action of external bodies, the ſerous membranes do not enjoy, in their natural ſtate, thoſe properties which eſtabliſh relations between ſuch bodies and the living organs; they have no animal ſenſibility nor contractility. Hence they would not ſerve the office of integuments to the body, nor the purpoſe of lining the organs in the place of mucous membranes: they would give us in ſhort no other ſenſation than that of an obſcure and indiſtinct feeling. Living animals exhibit no ſigns of pain when theſe membranes are irritated. External bodies brought in contact with ſerous membranes excite inflammation in them: and this method is employed in ſurgery for producing artificial adheſions of their ſides. When inflamed, animal ſenſibility is developed in them to a very high degree; theſe are among the moſt painful affections to which the body is ſubject.

This ſyſtem does not poſſeſs the ſenſible organic contractility; but the inſenſible organic contractility, and the correſponding ſenſibility, are kept in permanent exerciſe by the exhalation and abſorption habitual to this ſyſtem, and by nutrition. The two latter properties predominate, and the morbid affections conſiſt in alterations of them. Hence are derived acute and chronic inflammation, adheſions, effuſions of various fluids, &c. It is theſe, alſo, which are called into action in ſympathies; ſo that whether they are diſeaſed idiopathically or ſympathetically, ſerous membranes exhibit always a ſeries of phenomena ariſing from an increaſed interior motion, or from a loſs of power in the exhaling and abſorbing veſſels, and in the proper tiſſue; while in the animal and organic muſcular ſyſtems, the prevailing affections, marked in the one by convulſions and paralyſis, in the other by irregular motions of irritability, do not indicate any ſuch alteration of the tiſſue of the organ. Hence the latter ſyſtems, although frequently affected during life, preſent very few morbid changes after death, while the ſerous affords a vaſt field of obſervation to the morbid anatomiſt.

Sympathies.—The ſerous ſurfaces are often influenced by the affections of other organs. This is obvious in the organic diſeaſes of the heart, lungs, liver, &c. which, although theſe parts are entirely unconnected in functions with the ſerous organs, are almoſt always accompanied, in their latter ſtages, with collections of fluid in the large cavities.

Developement of the Serous Syſtem.—All the ſerous membranes are extremely thin in the fœtus; and the fluid which lubricates them is more unctuous, ſo that it ſeems to approach in its qualities to the ſynovia. Their growth correſponds to that of the organs which they cover. We cannot obſerve any marked change in their functions at the time of birth. For a conſiderable time they are extremely thin and tranſparent, but they afterwards grow thicker, and aſſume a dull colour.

This ſyſtem remains unchanged for a long time in the adult. The different membranes in their affections follow the ſame laws as the organs which they ſurround: thus the ſerous ſurfaces of the cheſt are moſt frequently affected in young, and thoſe of the abdomen in older ſubjects.

The membranes become more denſe and firm, and adhere more ſtrongly in old perſons. Their powers become weakened, abſorption is performed more languidly, and dropſies occur.

The *ſynovial* ſyſtem preſents two principal diviſions; one belonging to the articulations, the other to the tendinous ſheaths.

Synovial Syſtem of the Articulations.—The formation of the ſynovia has been very commonly aſcribed to the maſſes of fat found in the neighbourhood of the articulations, and has been regarded as a ſpecies of ſecretion. Theſe maſſes, which have been called ſynovial glands, conſiſt apparently of a merely adipous texture, covered by the ſynovial membranes, and ſo placed as not to be ſubject to any conſiderable preſſure in the motions of the joint. It was ſaid, that the ſynovia was poured out by fringed proceſſes projecting from their ſurfaces into the cavities of the joints. The following conſiderations will convince us that the ſynovia cannot be formed from this ſource. The bodies called ſynovial glands are not found in all the joints, and they do not exiſt in the ſheaths of tendons. We can diſcover nothing in them but maſſes of fat: inflation or maceration demonſtrates the cellular tiſſue belonging to them, and ebullition removes the fat, leaving nothing but collapſed cells like common cellular ſubſtance. They contain no trace of any glandular ſtructure, nothing of that peculiar parenchyma, unknown in its nature, but remarkable in its ſtructure, which diſtinguiſhes all glandular bodies. No excretory duct can be ſhewn in any of them. They do not exhibit in any caſe ſuch diſeaſed alterations as other glands diſplay, but participate only in the general affections of the ſurrounding cellular tiſſue.

Another ſource has been aſſigned to this fluid in the tranſudation of the medullary ſubſtance of the bones through their extremities: this explanation is ſo mechanical, ſo unlike any vital proceſs, and ſo inconſiſtent with all our views of the functions of the animal economy, that it is unneceſſary to refute it formally.

We

We must then consider the synovia as produced by exhalation from the vessels of the membranes. In this point of view it may be compared to the serum of serous surfaces, to which it is analogous in its albuminous composition, in its function of lubricating the surface, on which it is deposited, in its increased deposition under certain circumstances, and in its being taken up from the cavities by absorption.

The synovia is a transparent and viscid fluid: it is tenacious, so as to be drawn out into strings when touched with the finger, and has a slippery unctuous feel, which renders it very fit for the purpose of lubricating the articular surfaces, and making them glide easily against each other in the motions of the joint. Its quantity is not uniform in all joints; in the ankle, hip, shoulder, elbow, &c. it is abundant; while its existence can hardly be observed in the sterno-clavicular, sterno-costal and costo-vertebral articulations. This difference does not arise from the smallness of the surfaces; for some small joints contain much synovia. The quantity is always the same in the same joint; it cannot be increased, like the serous fluids, by transudation after death, nor is it, like them, influenced sympathetically by affections of other organs. It never exhibits those changes in appearance, which are so frequent in the fluid of serous cavities, as the milky turbid state, the white flocculi, the false membrane of coagulating lymph.

The synovial membranes, which constantly deposit and absorb synovia, belong to the joints of the body in the same manner as the serous membranes do to the great cavities. Each of these organs is therefore to be regarded as an entire bag expanded over the parts which form the joint; that is, over the surfaces of the articular cartilages of the ligaments, and the masses of fat called synovial glands, and including the inter-articular ligaments, when such exist, in complete sheaths. The various organs composing joints owe to it their smooth, polished, and shining surface. We can conceive the possibility of removing it from them by dissection, in which case it would form a bag without any opening. All the organs, over which it is expanded, are on its external surface, as the different viscera are on the outside of their respective serous membranes.

A synovial membrane is found in all moveable articulations; indeed, its office is so essentially connected with the motion of the part, that it may be deemed a necessary constituent of these joints. A fibrous capsule belongs to very few joints: the hip and shoulder offer examples of it. These joints possess two very distinct coverings. The external is fibrous, and represents a bag open above and below: it embraces, by its two openings, the surfaces of the two bones, and is continued into their periosteum, the fibres of the two organs being interlaced. The other is the synovial membrane, lining the former, and separating from it at its attachment to the bones, to be reflected over the articular cartilages. To the former, if to any part, the term capsular ligament should be applied; it must lead to very incorrect notions to give this name to the synovial membrane, the structure and functions of which are so foreign to those of ligaments.

Other joints have no fibrous capsule: the ligamentous fibres, instead of assuming the membranous form, are collected into fasciculi. The internal layer, or that composed of the synovial membrane, exists here, as in the former joints, and has exactly the same disposition with respect to the capsule, which it forms round the joint, and its reflexion over the articular heads. In these joints, too, anatomists often call it the capsular ligament. It has the same function in both kinds of articulation; that of secreting the synovia and confining it to the surface of the joint.

Simple inspection is sufficient to prove the existence of the synovial membrane in joints, where it exists alone, that is, not covered by a fibrous capsule. It can be very easily demonstrated in certain parts of other joints, as on the ligamentum teres, the synovial gland, and the neck of the femur in the hip, as well as where it is reflected from the fibrous capsule to the cartilaginous surfaces. On the surface of the fibrous capsule, and on the articular cartilages in all joints, its adhesion is so strong, that doubts may be entertained of its existence. It sometimes appears uncovered at some interval between the fibres of a capsule; and careful dissection, with maceration, enables us to detach it. The smooth surfaces of ligaments and cartilages can be owing only to a covering of this membrane, for those parts cannot derive that property from their own structure; articulations, which have no synovial membrane, have not this smooth surface, as the symphyses of the pelvis.

When a part passes through a joint, as the tendon of the biceps at the shoulder, the synovial membrane is reflected over it, so that there is no opening for the synovia to escape through.

As the form and office of the synovial strongly resemble those of the serous membranes, the organisation is also analogous. It is chiefly cellular, as we may prove by dissection, inflation, and maceration. Its external surface is every where covered by cellular tissue, which we find gradually more and more condensed as we approach the membrane. No kind of fibre can be distinguished in it. It has a degree of transparency when dissected out of a joint. In all points of its texture, in its exhalants and absorbents, it resembles the serous membranes.

Properties.—The extensibility and contractility of tissue are seen in the distention of joints in the hydrops articuli, and their subsequent return to their original size. The membranes admit, however, only of a gradual extension, and are torn by the sudden force applied in luxations.

Organic sensibility is the only vital property which they possess in the ordinary state; no sign of pain is produced, when they are exposed and irritated in living animals. Inflammation increases this sensibility and converts it into the animal kind; most excruciating pain is experienced from inflamed joints. The exhalation and absorption constantly carried on by these membranes, prove that they possess the insensible contractility.

These membranes are not affected by diseases of other organs. In acute diseases of important viscera, while the skin, the mucous surfaces, the cellular tissues, the nerves, &c. exhibit a greater or less sympathetic disturbance, the synovial membranes are completely quiet. In this respect they resemble the bony, cartilaginous, and fibrous systems.

Developement of the Synovial System.—The membranes are proportionally large in the fœtus and child, because the articular surfaces are large; they are also very thin. There is nothing peculiar in the synovia. The membranes grow more dense, and less transparent, in the old subject, and produce less synovia: they acquire a rigidity, which is unfavourable to motion. But they do not become ossified.

Synovial membranes are sometimes accidentally developed. When the head of a bone is dislocated and not replaced, a smooth moist cyst is formed round it, by condensation of the surrounding cellular membrane, having very much of the appearance of a synovial membrane, and performing its office in facilitating the motions of the part.

Synovial System connected with the Tendons.—This entirely resembles the preceding system in its nature, and differs from it only in situation: often indeed they are confounded together: thus those, which belong to the heads of the gastrocnemius, to the extensors of the knee and to the popliteus, are continuous with the joint of the knee, the same membrane belonging both to the articulation and to the tendon. Very few of these tendinous synovial membranes are found in the trunk, almost all of them occupy the limbs, in which they favour the motions of the tendons. They are found, 1, where a tendon turns over a bone at an angle, as at the passage of the peronei behind the outer ankle, and of the obturator internus over the ischium; 2, where a tendon glides against a bony surface without making any turn, as the tendo Achillis at the os calcis, the gluteus maximus at the great trochanter, &c.; 3, where a tendon plays in a fibrous sheath, as the flexors of the toes and fingers on the phalanges.

The synovial membranes of tendons, like those of the joints, form bags without any opening, expanded on one side over the tendons, and on the other over the organs with which the organs are in contact. From this disposition, and from the nature of the fluid with which they are lubricated, they have been called bursæ mucosæ, under which name they are generally described. It follows, that every tendinous synovial membrane must possess two surfaces, a smooth one, forming the interior of the bag, which is every where free and contiguous to itself, and an adherent one attached to the surrounding parts. The smooth surface is constantly moistened with a fluid of the same nature as the synovia of the joints, formed like it by exhalation, and not, as some have represented, by reddish fatty bodies placed on the outside of the membrane, which do not exist in general, and have no glandular texture when they do exist. This fluid in general is less abundant than in the joints; but the quantity varies in the different bursæ. It is sometimes increased in quantity, forming a species of dropsy, which is called a ganglion: this kind of tumour never exists in the fingers, because the fibrous sheaths which include the synovial membranes of their flexor tendons are unyielding. Often these ganglia are completely new formations, cysts developed in the cellular tissue.

The adherent surfaces of the membranes are fixed on one side to the tendons, to which they are closely attached, but not with equal firmness in all cases; it may be detached from the obturator internus, the psoas, &c., but in general it cannot be separated. On the other side it is fixed to the periosteum, which generally assumes the structure of fibro-cartilage. To this the membrane adheres as the articular synovial membranes do to the cartilages of their respective joints; that is, we cannot detach it, and shew it separately, but infer its existence from the polished surface of the part. Sometimes it is expanded over a fibrous capsule, instead of a bone. After covering the tendon, it is continued in some cases over a portion of the muscular fibres, as in the obturator internus. Where the membranes are reflected from the tendons to the surrounding organs, they are covered in general by a considerable quantity of cellular tissue: but in the case of tendons running in fibrous sheaths, they line those sheaths.

These membranes must obviously participate in the motions executed by the tendons, to which they belong: they will be drawn backwards and forwards as the tendon itself is moved.

The very various forms, which the bags of the tendinous synovial membranes present, may be reduced to two general modifications. The one kind are rounded bags, covering only one side of the respective tendons, having no internal folds, and never surrounded by fibrous sheaths. The others, belonging particularly to the flexors of the toes and fingers, and to other tendons about the wrist and ankle, consist in the first place of a cylindrical sac lining the canal, in which the tendon runs: it is then reflected over the tendon, which it covers on all sides, composing for it a complete sheath. This kind of membrane thus represents two cylindrical canals, one lining the bone and fibrous sheath, and the other covering the tendon, continuous with each other at the two ends, where the reflexion produces two cul-de-sacs. Folds are often seen in these, passing from one part of the membrane to the other: the synovial membranes of the digital flexors exhibit them.

Their organisation is exactly analogous to that of the articular membranes. The structure is principally cellular, and distinguished by its softness: very few blood-vessels are seen, but the exhalants and absorbents prevail. The former become distended with blood under inflammation, and give to the membrane a more or less deep red tint. In this state synovia is not produced; and sometimes adhesions take place.

The vital properties, and those resulting from organisation, seem not to differ from those of the preceding system. Like it, this is never affected sympathetically: all its diseases are local.

The obvious effect of these membranes is to facilitate the motions of the tendons over the bones and other parts in contact with them, by giving to the opposed surfaces a perfect polish, and lubricating them with a slippery fluid.

They are thin and delicate in the fœtus and child, more dense and firm in the adult, and become rigid in old age: at the latter time they produce but little fluid, and are consequently dry. This state probably concurs with other causes in impairing the power of motion in the old subject.

Several of the bursæ mucosæ vary in different bodies. Sometimes this is only a mass of cellular tissue, in the place of that belonging to the gluteus maximus. These bursæ are always very dry when they exist, so that synovia can hardly be seen in them. They resemble, in that respect, the articular synovial membranes of the ribs, clavicles, &c.

Fibrous Membranes.—These comprehend the fasciæ of the limbs, &c., the periosteum and perichondrium, the dura mater, sclerotica, albuginea, the proper coverings of the kidnies, spleen, &c., the covering of the corpus cavernosum, &c.; all forming exterior investments of the organs to which they belong. These parts are not, like the stomach, intestines, lungs, bladder, &c., which are covered by serous membranes, subject to alternate enlargement and diminution: that would not suit the properties of fibrous organs. The membranes are moulded exactly to the form of the parts, and, with the exception of the dura mater, do not present the numerous folds seen in the serous membranes. Both their surfaces are adherent, in which they differ from the serous, mucous, and synovial membranes.

One of these surfaces, intimately connected to the organ, seems to send numerous processes into it. In the testes, corpus cavernosum penis, spleen, &c. are seen numerous fibres crossing in various directions, and attached to the fibrous membranes of these organs. On these, together with the membrane, the form of the part seems greatly to depend. Bony matter is thrown out in a rough and irregular form, when the periosteum no longer covers it: the figure of the testis is altered, when the albuginea is injured, &c. These fibres in the interior of the organs are not, however, of the same nature with the fibrous membranes: they cannot be deemed processes of those membranes. By boiling the corpus

pus

pus cavernosum penis, or subjecting it to any other process, the interior spongy tissue and the outer fibrous covering always remain distinct in their appearance: there is no continuation of the one into the other.

The opposite surfaces of fibrous membranes are joined to the surrounding organs with various degrees of firmness, from the loose attachment of the corpus cavernosum to the close adhesion of the dura mater. In general, the fibrous membranes and other fibrous organs have a great tendency to adhere closely to the serous and mucous organs. The connection between the dura mater and arachnoid, the tunica albuginea and vaginalis, the fibrous capsules and the synovial membranes, shews this in the serous membranes. So intimate is the connection in these cases, that it is not possible to separate the parts by dissection in the adult. When fibrous and mucous surfaces meet together in an organ, they become completely confounded: this is seen in the pituitary membrane, in the membrane of the sinuses of the nose, in the ear, &c. In all these parts, the periosteum is not separable from the mucous surface. The vas deferens, the Fallopian tube, the ureter, seem to be fibro-mucous organs.

These membranes have, in general, a very close texture, and a remarkable thickness: they consist of a single layer. The dura mater seems to form an exception to this rule, by the folds which form the falx and the tentorium cerebelli; but we cannot point out two distinct layers in the membrane, except at the sinuses. They possess more vessels than all the other divisions of the fibrous system, and are perforated by numerous apertures for the passage of these vessels, which in general pass through them, in order to arrive at the organs which they cover. These openings, each of which is larger than the branch perforating it, distinguish the fibres from the serous membranes, which are always reflected, instead of being opened, for the purpose of admitting the vascular system into their respective organs. The description of the particular membranes will come under that of the organs to which they belong. We shall except the periosteum, which ought to be considered in a general way, both because it is a covering common to the whole bony system, and because it is a kind of connecting centre to all the organs of the fibrous system.

The periosteum surrounds all the bones in every part, except where they are covered by cartilage. It is hard, strong, of a greyish colour, remarkably thick in the early years of life, and proportionally thinner in the adult. The old anatomists conceived that it was prolonged from one bone to another, over the articulation, so as to constitute a continued bag for the whole skeleton. This is an incorrect notion. The periosteum is interlaced at the joints with the ligaments, which may thus be regarded as a medium of communication between the coverings of the different bones. It is in this way only that we can regard it as continuous over the whole skeleton. It does not exist in the crowns of the teeth, nor on the bony productions rising from the head in certain animals. It is feebly united to the bone in infancy, particularly at the middle of the long bones: the adhesion becomes strong in the adult; and is extremely firm in the old subject, in which the membrane is very thin. Numerous processes extend from this membrane into the bone: the number of these is much greater at the extremities of the long bones, and on the short bones, than at the middle of long, and over the surface of broad bones; all which we should have inferred, from observing the proportion of apertures in these situations. These prolongations accompany blood-vessels, and line the canals which penetrate the bones: they do not reach the medullary cavity, but are confined to the bony tissue, establishing relations between it and the membrane from which they proceed. In consequence of this connection, the destruction of the periosteum is accompanied by the death of the corresponding part of the bone.

The relations of the periosteum to the surrounding organs are very various: in most cases the muscles lie on it, and are connected, according as they are capable of executing more or less considerable motions, by looser or closer cellular texture.

The direction of the fibres in this membrane is nearly analogous to that of the bones, particularly in the long and short ones; but it has not a radiated arrangement in the broad bones. They vary in length, and the superficial ones are the most extensive. Its vessels are derived from those of the neighbouring parts. Their ramifications form in the membrane a net-work, which injections shew very clearly, particularly in children: they are either lost in the membrane, or penetrate the tissue of the bone, or return into the neighbouring parts to form various anastomoses.

The periosteum receives the insertion of the tendons, ligaments, and aponeuroses. This attachment appears foreign to the bone in the child. If we detach the membrane, all these organs are brought away at the same time; but, as ossification extends to the internal plates of the periosteum, the fibrous organs seem identified with the bone in the adult.

In the fœtus it is soft, spongy, and containing much gelatinous fluid: it dissolves in water readily. Its fibres at this time are indistinct: they become more visible as age advances; the softness of the tissue is diminished, and its strength increased. The periosteum is extremely firm in the old subject: it resists ebullition almost as much as the ligaments. When the bones are boiled, it cracks in various parts, because its fibres are shortened and detached from the bone; but that which remains adherent is very difficultly converted into gelatine.

The functions of this membrane do not seem to be very satisfactorily ascertained. An opinion has been entertained that it serves to protect the bone from the pressure of the surrounding moveable organs, as the muscles and arteries. It has been supposed to be very much concerned in the formation of bone; but we cannot accede to this view of the matter. (See BONE.) It may form a kind of barrier, confining the progress of ossification within certain bounds. Bichat regards it as connected essentially with the functions of the fibrous organs attached to it. He considers that it is placed on the bony system, as a solid point of support, which enables it to bear the efforts of the various fibrous organs.

The *perichondrium* is a membrane surrounding the cartilages, except those belonging to the articulations, analogous in its structure and offices to the periosteum. It is thin and fibrous; less closely united to the organs, which it covers, than the periosteum, because they have fewer pores, and therefore receive fewer processes from the membrane: hence there is a less intimate connection between its life and that of the cartilage, than between that of the bone and the periosteum. Its blood-vessels are few. Bichat removed it from the thyroid cartilage of a dog, and no exfoliation followed.

For the vital properties of the fibrous membranes, the reader is referred to the article FIBROUS *System*, where the subject is considered in a general point of view.

The compound Membranes.—The serous and fibrous membranes have a great tendency to adhere together, and exhibit this character wherever they are brought into opposition, as in the case of the arachnoid and dura mater, the tunica albuginea and vaginalis, the synovial membranes and fibrous capsules.

capsules of joints, &c. The two component parts of such membranes are so closely united, that it is impossible to separate them by dissection: however, they are clearly distinguished by their texture and properties.

The serous and mucous membranes are generally separated by a muscular stratum, as in the intestinal canal and bladder; and where they are not, as in the gall-bladder, the cellular substance belonging to the mucous is too copious to admit of the close adhesion necessary to form a compound membrane.

The fibrous and mucous membranes are in many cases consolidated together, as in the ureter, vas deferens, pituitary membrane, lining of the tympanum, &c. They are connected inseparably in these situations. In all, the mucous is the most important, as it is the seat of the functions of the part: the fibrous is accessary, and furnishes additional support and strength to the mucous.

There are several membranes, which do not come under the preceding classification: such are the fibrous coat of the arterial system (see Heart); the lining both of the arteries and veins (see Heart); that which lines the medullary canal of bones, and contains the marrow (see Medullary *System*); the iris and choroid coat, and retina (see Eye); and the pia mater, see Brain.

Membrane is a term also frequently applied in the English language to the cellular substance; *cellular membrane* therefore is exactly equivalent to the latter expression. A general account of this very important animal tissue is given under the head of Cellular *Substance:* we propose to consider it in a more extensive way in the present article, and particularly to exhibit the ingenious views of Bichat, as contained in the first volume of his "Anatomie Generale."

The cellular substance, surrounding the various organs of the body, forms at the same time a connecting medium which joins them together, and an intermediate structure which insulates them. It extends into the interior of the same organs, and is essentially concerned in their structure. We should regard it, first, in relation to the particular organs; and secondly, in a general manner, independently of other parts. In the first of these divisions we have to consider the cellular organ under two points of view: 1st, as composing a covering for each part; and 2dly, as forming one of the essential bases of its structure.

I. *Of the exterior Cellular Texture of each Organ.*—Some parts are covered on one surface only, as the skin, mucous and serous membranes, arteries, veins, and absorbents; while others are surrounded on all sides.

The corion of the skin contains, as we have shewn under the article Integuments, a large quantity of cellular tissue, and anatomists have generally regarded it as formed by a condensation of this tissue. Besides this, a stratum of cellular substance, varying in quantity and density, lies under it in all parts of the body. At the median line the subcutaneous tissue is rather more dense than in other situations, and adheres more closely to the skin; this may be seen in the face, on the sternum of the linea alba, and over the spine. Bichat regards it as marking in an obscure way the symmetrical division which characterises the organs of the animal life; but we cannot insist much on it, as there are no traces in the neck. This author states that the air was confined to one side in some of his experiments on emphysema; but that it generally passed the line.

1. The subcutaneous tissue is remarkably dense under the scalp; it is loose and abundant in the face. By its laxity in the trunk it favours the motions of the large muscles in that situation. It is distributed almost uniformly in the limbs, except that it is dense in the palms and soles, where consequently the skin is more closely united to the aponeuroses, and anasarcous depositions are formed with difficulty. It is also more dense and close over the annular ligaments; and hence the constrictions which the limbs of children present in these situations, as the fat does not penetrate easily into cells so closely approximated.

The subcutaneous cellular tissue bestows on the skin its power of motion with respect to the organs that it covers; this is exemplified in the movements of the trunk and limbs, in the effects of external bodies brought in contact with the surface, in the cutaneous coverings acquired by large tumours, as herniæ, sarcocele, &c. at the expence of the surrounding parts. From the same cause arises the facility of motion in organs situated under the skin, as the muscles.

It contains a larger proportion of serous fluid than other parts of the cellular substance, and is more liable to preternatural accumulations of that fluid, probably on account of its greater laxity. If the skin and subjacent tissue be stripped from an anasarcous lower extremity, it will appear very little larger than a healthy limb treated in the same way.

2. The mucous membranes have the same relations to the cellular substance as the skin, of which they are continuations, and to which their structure bears considerable analogy: the structure occupying their surface is called by Bichat tissu soumuqueux. It is much more compact and dense than the former, and the adhesion of the mucous system to the surrounding parts is consequently much more close. Hence it is difficult to separate the mucous membranes perfectly, and impossible to produce emphysema under them artificially. Air is never seen in this tissue in the most extensive natural emphysema, nor is water ever deposited in it in the most general anasarca. Indeed the hollow organs would have their functions destroyed by the obliteration of their canals, if the submucous were liable to the same distention as the subcutaneous tissue. This firmness in the former tissue enables it to serve as a point of attachment to the muscular fibres, which belongs to the stomach, intestines, bladder, &c.

3. The adherent surfaces of serous membranes are covered by cellular tissue, called by Bichat tissu souséreux, which is in general loose and abundant. In some parts, however, the union is so close that no cellular substance can be discerned; as in the tunica vaginalis and albuginea, the arachnoid and dura mater, &c.: these constitute sero-fibrous membranes.

4. Arteries and veins are connected to the surrounding organs by a loose and easily lacerable cellular substance. (See the account of their structure in the article Heart.) The absorbing vessels are probably furnished with a corresponding covering; but their minuteness prevents us from ascertaining this point by direct investigation.

5. The various excretory tubes are surrounded by cellular tissue. All these have a mucous lining, which is covered by a dense and firm stratum of matter, differing in the different tubes, and the exact nature of which is probably not yet well understood. It seems doubtful whether we ought to assign this exterior covering to the cellular tissue. See Gland.

The organs of the body, except those which have been just mentioned, are surrounded on all sides by a more or less abundant cellular stratum, which insulates them, and interrupts those communications which would connect the vitality of one part to that of another in too intimate a manner, if their juxtaposition were immediate. The serous vapour and fat of the cells probably contribute to this insulation of vitality; but the essential difference, between the proper life of the cellular substance, and that of the organs which it incloses, renders that tissue very capable of fulfilling this office,

office, independently of the fluids which it contains. The confinement of diseases to particular organs is ascribed by Bichat to this insulation of their vitality. We meet every day with diseased organs covered by healthy serous membranes, with catarrhal mucous membranes surrounded by sound parts: the numerous cutaneous eruptions do not affect the subjacent organs, &c. On the other hand, diseases are very often communicated from one part to another. A phlegmonous inflammation involves all the surrounding parts: the rheumatic affection of a joint produces exterior swelling, and disease of the ligaments of the knee is accompanied by an analogous phenomenon. Nor are diseases alone communicated from one part to another: the effects of remedies often act in the same way, as for instance, blisters and poultices. If the cellular substance has any influence on these changes, how are we to account for results apparently so contradictory under similar circumstances? Will it not be more philosophical to confess that we are ignorant of the causes, by which the communication of diseases is influenced and modified, than to adopt, in the absence of all direct proof, a mode of explanation which so frequently fails? When Bichat tells us, in cases where disease is confined to one organ, that the cellular atmosphere, by possessing a different kind of vitality, prevents its propagation; and, in opposite instances, that this atmosphere becomes charged with emanations raised from the morbid part, or that its vital powers experience a change analogous to that which has affected the diseased organ, does this apparatus of words impart to us any further knowledge than that of the simple fact, that morbid changes sometimes are, and sometimes are not, propagated from one organ to another?

The quantity of cellular tissue surrounding any organ bears a relation to the motions which it is capable of executing; and is more abundant in proportion as these motions are more extensive. Hence it is seen in considerable quantity about the large arterial trunks, the eye, the uterus, bladder, the large joints, as the hip and shoulder. By the extension and contraction of its cells it is very capable of accommodating the motions of the organs, particularly their dilatation and contraction. Parts, which enjoy extensive power of motion, and yet have but little cellular tissue on their surface, as the viscera, and the articular ends of bones, are surrounded by serous or synovial membranes. In many instances organs with very little motion are covered by an abundance of cellular tissue: the kidney, testis, thyroid gland, and pancreas are examples.

II. *The internal Cellular System of the Organs.*—After surrounding all parts, this system enters into their substance, and forms one of its principal elements. In those apparatuses, which are an assemblage of several systems, each is united to the surrounding ones by it; as the different coats of the stomach, intestines, bladder, &c. Again, it enters largely into the composition of the organic systems: it surrounds their vascular and nervous ramifications, and unites the various homogeneous parts that compose them. Thus, says Bichat, each portion of an organ has a covering, performing the same office with respect to it, that the general covering does to the whole organ; it forms an atmosphere, limiting and protecting the vitality of each fibre, or serving, (more readily on account of the greater juxtaposition) as a means of communication from one to the other.

This interior cellular tissue is only a means of union, and preserves all its own properties; it is insensible in the nerve, incapable of contraction in the muscle, and unconnected with secretion in the glands. It is often affected alone in an organ; hence the numerous tumours in the liver, which have the glandular tissue perfectly healthy.

The texture of many organs is so close that the cellular tissue is but little apparent, and its very existence has been denied. In tendons and fibrous membranes maceration renders it discernible: ebullition has a similar effect, by dissolving the gelatine which a part may contain. In all instances, even in bones and cartilages, the production of granulations, which are essentially of a cellular nature, demonstrates the existence of this tissue. The conversion of bones into a soft and fleshy state, and the production of fungous tumours in other systems, by rendering the tissue more loose, demonstrate the cellular substances.

Of the Cellular System considered independently of the Organs.—In the interior of the cranium this tissue seems to be almost deficient. Yet the pia mater is formed by it; and a small quantity of a very fine and perfectly transparent kind is seen where the nerves quit the surface of the brain. There is no possibility of demonstrating cellular tissue in the substance of the brain, unless perhaps by its fungous tumours. Through the optic foramina and the superior orbital fissures, the cellular substance of the cranium communicates with that of the orbit; through the holes of the cribriform plate with that of the nose; through the various apertures of the basis cranii, and the numerous but minute pores about the sutures, with the corresponding external parts. It is more abundant, but still in comparatively small quantity, on the outside of the cranium, and communicates evidently with that of the face, particularly in front.

It is very abundant in all parts of the face: the orbits are filled with it; the hollows of the cheeks, bounded by the buccinator, masseter, and zygomatic muscles, contain it in large quantity, as well as all the parts about the tongue. The nose and its sinuses have a very small proportion. On its existence in greater or smaller quantity, the appearance of the countenance, with respect to fulness or sharpness, depends. The expression is regulated by the muscles. It communicates with that of the neck by its subcutaneous portion, by what accompanies the vessels, particularly in the triangular space lodging the parotid, and by the intervals of the muscles about the root of the tongue.

Very little is found in the vertebral canal, between the arachnoid and the medulla spinalis and its nerves: there is none between the arachnoid and dura mater. It is more copious on the outside of the latter, particularly towards the lower parts, where it is very loose. On the outside of the spine the muscles are very numerous and closely arranged, and the cellular tissue very sparing behind; it is copious on the front. It accompanies the carotids on the neck, the aorta and its large branches, the azygos, and the vena cava in the chest and neck. This disposition is very favourable to the formation and extension of depositions of pus.

The neck is a very muscular part, and contains much cellular tissue, besides what belongs to the spine, particularly on its sides, where the lymphatic glands are found. In this situation it communicates with that of the chest, by the superior opening of the latter cavity. It also communicates with the upper limbs above and below the clavicles.

The largest quantity of cellular tissue occupies the middle line of the chest: there is much of it in the mediastinum, about the pericardium, and the large vessels. In the parts occupied by the lungs, the quantity is considerably less. The communications between it and the abdominal cellular tissue take place, 1st, at the various openings of the diaphragm, particularly those which transmit the aorta and œsophagus, for the vena cava is too closely united to its opening to allow of such communication: 2dly, through the intervals of the diaphragmatic fibres, particularly at the triangular space left between those attached to the xiphoid cartilage.

cartilage. There are communications from within outwards at the intervals of the intercoſtal muſcles; but theſe are very trifling, and conſequently the internal affections ſeldom have any influence on the external parts.

On the outſide of the cheſt, the cellular tiſſue is abundant above; it encloſes the mammary glands, and produces the elegantly rounded forms which charm us in the female; it contributes to the bold prominence which is the attribute and character of male ſtrength. There is much of it under the pectoral muſcles, but the quantity decreaſes very ſenſibly downwards.

The abdomen contains more cellular tiſſue than the cheſt. It is accumulated in large quantity about the large arterial and venous trunks, and accompanies them to their reſpective organs. It is alſo very abundant along the back of the peritoneum, particularly about the kidney, but much more ſparing on the front and ſides of the abdominal parietes. It communicates with that of the pelvis all round the peritoneum, and with that of the lower limbs at the inguinal canal, and more particularly at the crural arch. In the latter ſituation, the pus generally deſcends in lumbar abſceſſes.

The outſide of the abdomen has the uſual ſubcutaneous ſtratum, which is continuous with that of the pelvis and lower limbs. Between the abdominal muſcles there is a moderate quantity. The outer and inner portions of cellular ſubſtance communicate through the muſcles, particularly at the poſterior and lateral regions: the fluid of lumbar abſceſſes ſometimes takes this direction and preſents in the loins.

Few parts have a more abundant diſtribution of cellular tiſſue than the pelvis; it is placed very copiouſly round the bladder, rectum, and uterus. The great dilatations of which the organs are ſuſceptible, and the unyielding nature of the parietes of the pelvis, explain this arrangement. The nature of the abſceſſes, which occur about the anus, and the diffuſion of urine from ruptures of the urethra, are modified by this ſtructure. It communicates with that of the lower limbs by the iſchiatic notch, the foramen ovale, and the arch of the pubes. The outſide of the pelvis has alſo much cellular ſubſtance: it is moſt copious in front, about the generative organs, particularly in the labia and ſcrotum, and more abundant on the ſides than behind.

Both in the upper and lower limbs the quantity of cellular tiſſue conſtantly decreaſes from above downwards. It is very conſiderable round the upper articulation of each: the hollow of the axilla is almoſt entirely filled with it; the bend of the thigh does not contain ſo much. There are large cellular intervals between the muſcles of the arm and thigh. The elbow has much leſs than the ham, the deep hollow of which holds a large quantity. In the fore-arm and leg the muſcles are more approximated, and the cellular ſtrata conſequently thinner. Towards the lower part of theſe two diviſions of the limbs, it is ſtill more diminiſhed in quantity. Yet the ſole contains much more than the palm. The difference in the extent of motion in the different parts of the limbs correſponds to this arrangement.

Concerning the general forms of the cellular tiſſue, the figure and permeability of the cells, and the ſerous fluid which lubricates them, we refer to the article CELLULAR *Subſtance*. We have only to remark here, that the capacity of the cells is extremely various. When diſtended with fat or ſerum, they are two, three, or four times as large as in the empty ſtate. Theſe variations in capacity produce the differences in the volume of the body in the ſtates of embonpoint or emaciation, in which all the other parts, as nervous, tendinous, and muſcular fibres, &c. remain unchanged, and the cellular tiſſue alone is altered.

When the cellular ſubſtance of a living animal, or of one recently killed, is expoſed to cold air, a vapour ariſes from it, as it does from ſerous ſurfaces. This moiſture ſeems juſt ſufficient, in the natural ſtate, to maintain the cells ſoft and pliant.

To the general obſervations on the fat, in the article CELLULAR *Subſtance*, we have a few remarks to add. Its proportion varies in the different organic ſyſtems. The arterial and venous tunics, the lymphatic glands, the brain and ſpinal marrow, contain none. There is always ſome in the intervals of the nervous fibres, as may be proved by drying them. Generally the muſcular fibres of the animal life contain a tolerably large proportion; but thoſe of the organic very little. Its place is ſupplied in the bones by the medullary ſtructure. The cartilaginous, fibrous, and fibro-cartilaginous ſyſtems, are almoſt entirely deſtitute of it. Sometimes it is obſervable in the glandular ſyſtem, as in the parotids, and about the pelvis of the kidney; but in other parts, as the liver, proſtate, &c. no trace is diſcernible. The ſerous and cutaneous ſyſtems are ſurrounded by much fat, but contain none in their tiſſue: the ſame obſervation is true of the mucous alſo. The epidermis and hair have none. Thus we ſee that the organic ſyſtems in general contain very little fat: the organs themſelves have but a ſmall quantity between their different parts. In general there is hardly any between the coats of the ſtomach, inteſtines, bladder, &c.; between the perioſteum and bone; the bone and cartilage, &c. It is accumulated principally in the intervals of the organs. In this point of view the cranium and face exhibit oppoſite arrangements; it is abundant in the latter, and deficient in the former, particularly on the inſide. There is a tolerable quantity in the neck. Very little exiſts about the lungs, but much round the heart: and there is a large depoſition on the outſide about the breaſts. In the abdomen, it lies principally behind, in the neighbourhood of the kidney, in the meſentery and epiploon: there is much in the pelvis about the bladder and rectum. It follows the ſame arrangement in the limbs as the cellular tiſſue, being more abundant at the upper parts, and about the large articulations, than in other ſituations.

All the fat in the child is concentrated under the ſkin: the omentum, and indeed the reſt of the abdomen, contains none, except perhaps a few flocculi about the kidney. The cheſt contains hardly any more, and the intermuſcular tiſſue is almoſt every where free from it. In the adult, the abdominal fat exceeds the proportion of the ſubcutaneous: the rounded coutours, by which all the muſcular forms are concealed in the early years, are rare at the latter period. Theſe obſervations, however, concerning the proportions of fat, as connected with different ages, admit of frequent exceptions.

The fat is ſometimes accumulated in an unnatural quantity: it conſtitutes in ſuch caſes a real diſeaſe. (See CORPULENCE.) The oppoſite circumſtances to theſe, which produce this unnatural load of fat, cauſe emaciation.

The fat is almoſt always firm in the dead body, but it approaches more nearly to the liquid ſtate during life: its condition, however, is not uniform in all parts, the ſubcutaneous being the moſt ſolid, and that of the omenta moſt fluid. It is not ſo fluid in the living body as expoſure to heat renders it after death: its conſiſtence indeed muſt depend on other cauſes than temperature, as it varies ſo much in different parts of the body under the ſame heat. It is whitiſh and very firm after death in young animals: hence there is a ſtriking contraſt between the ſolid feel of the ſkin in a young ſubject, and the yielding ſenſation which it offers in the adult. It is collected into ſmall and more or leſs rounded

 granules

granules in the fœtus; a remarkable and almost insulated globular portion, which can easily be drawn out entire, occupies the hollow between the masseter and buccinator muscles. It turns yellow as age advances, and acquires a different odour and taste: every one must have noticed the difference between that of veal and beef, and the distinction is not less strongly marked between that of a young and old person.

A yellowish, transparent, and semifluid substance, with a gelatinous aspect, is found about the hearts of those who have died from dropsy, phthisis, or other tedious debilitating diseases, and occupies the place of fat. It is also seen in other situations, but less frequently; and seems rather gelatinous than oily.

We have nothing to add to the remarks in the article CELLULAR *Substance*, concerning the mode in which the fat is formed; and we refer the reader to FAT for the history of its chemical properties.

Organisation of the Cellular Substance.—The proper tissue, which composes the basis of this system, consists of a transparent web, disposed in plates of an uniform appearance, and so thin that they may be compared to soap bubbles; and of whitish filaments crossing these in various directions, and forming with them cells. This structure may be seen by taking a portion of the cellular matter of the scrotum, extending it and observing it against the light. The filaments are approximated, and seem to touch each other when the part is left to itself; when it is distended, the intervals left between them are larger, and the intermediate laminæ more distinct. Bichat conceives that the filaments are absorbents or exhalants, or made up by the union of the laminæ, where they form cells. The plates are tolerably dense when the cellular tissue is contracted; when air is forcibly impelled among them, they are reduced into a kind of thin froth, in which we could hardly suppose that vital properties could reside.

In all parts where fat or serum is deposited, we see true cells, communicating together; and the great accumulations of such fluids are deposited in these cells. But the submucous tissue, and that which composes the outer coverings of arteries, veins, and excretory tubes, seems to be composed entirely of condensed and approximated fibres, without any plates, and consequently without any cells.

Composition of the Cellular Tissue.—Chemists have placed it in the class of white organs, or such as furnish a large quantity of gelatine. Solution of tan causes a considerable precipitate from water, in which it has boiled. Yet the effect of various agents on it is very different from what they produce on the fibrous, cutaneous, cartilaginous tissues, &c.

It is quickly dried in the air, but without assuming the yellow tint of the fibrous tissue; when plates of it are dried, it exactly resembles a serous membrane treated in the same manner. In this state it is perfectly flexible; it recovers its original appearance only in part, when immersed in water.

It yields to putrefaction less readily than most other tissues, than the glandular and muscular organs for example. This property is particularly observable in the submucous tissue, and in that which forms the outer covering of arteries and veins. The same observation may be made concerning maceration: the exterior tissue of arteries is hardly changed in three months; the subcutaneous, the intermuscular, and other parts of the system, yield more quickly. It resists longer when exposed alone, than in conjunction with parts which decay quickly; and this resistance is the more remarkable, since the nature of the tissue renders it accessible to the action of water at all points. The latter circumstance must also render it more subject to the influence of ebullition; yet it does not yield quickly, and the exterior tissue of arteries, excretory tubes, &c. resists for a long time. The phenomena produced by boiling are analogous to those observed in other organs treated in the same way. It is not changed until a froth rises to the surface; it is then reduced in size, rendered firmer and elastic, and is curled up. After a certain time, as the boiling is continued, it becomes soft again, and is broken by the slightest force. The continued action of boiling water gradually melts it.

The gastric juice acts on it less quickly than on the muscular fibres.

Thus the cellular tissue seems to combine two opposite characters, softness and pliancy; by which it facilitates the motions of organs; and considerable resistance to the operation of various agents.

This tissue is distended with air in the bodies of the drowned, so that they float: probably the air is disengaged from organs containing a great deal of blood, as the muscles, glands, &c., and not from the cellular tissue. A similar phenomenon is observed in bodies buried under the earth, out of the contact of air; but it does not often take place in those left in the open air.

The blood-vessels of the cellular tissue are not numerous in the natural state. It is whitish, when observed in a living animal: large trunks pass through it to the neighbouring parts, and send off branches, which are lost in the tissue. After some exposure the number of these vessels is increased, as the red blood gains admission into the exhalants.

Successful minute injections have a similar effect in the dead body; they make it appear like a vascular network.

The exhalants are proved by the production of apparently new vessels where the part is exposed during life, and by the effect of injections; by the natural and the morbid depositions of serum and fat into the cells, &c. These vessels are very numerous in the present system: they are subservient to its nutrition, and to the habitual exhalation, of which it is the seat.

Absorbents cannot be shewn by actual inspection, nor by injection; but their existence is proved by phenomena: 1, by the natural and constant absorption of the serum and fat; 2, by the removal of unnatural accumulations of either of these fluids; 3, by the absorption of air in emphysema, or of fluids injected into the cells, &c. This system, indeed, seems to be a principal source of the absorbing vessels, at least of such as convey lymph. Some have considered it as formed exclusively of exhalants and lymphatics. Each cell is a reservoir, placed between the exhalants which terminate in it, and the absorbents which arise from it; we see the mouths of neither of these vessels: the cells are on a small scale what the serous cavities are on a larger.

Many nerves are seen going through the cellular tissue; but we do not know that any filaments terminate in it.

Properties of the Cellular System.

1. *Properties resulting from Organisation.*—The extensibility of tissue is seen on a variety of occasions: all the motions of the body call it into exercise; the arm cannot be elevated without the cellular substance of the axilla being drawn out to twice or thrice its natural length, and the motions of the neck, the thigh, and indeed all other parts, present analogous phenomena in different degrees. Whenever any organ is drawn away from a contiguous one, the connecting tissue must be lengthened. In the distentions of the hollow viscera there is a similar process.

process. In the accumulations of ferum or fat, of which this tiffue is fo frequently the feat, in the formation of tumours of all kinds, in the diftentions of the abdomen or other cavities, the exercife of this property is clearly obferved, and indeed is abfolutely neceffary to the production of the phenomena.

The different divifions of the fyftem poffefs this property in very different degrees. The fubcutaneous, the intermufcular, and that which covers ferous membranes, enjoy it to a much greater extent than that which furrounds arteries, veins, and excretory tubes: from its indifpofition to yield in the latter cafe arifes the flow growth of aneurifms. Wherever laminæ, and confequently cells are found, the extenfibility can be brought fuddenly into action: thus emphyfema diftends the whole body to an enormous degree in a very fhort time, and fractures and contufions are followed by very rapid and confiderable tumefaction.

When the diftending force is carried beyond a certain point, the tiffue is firft rendered very thin, and then broken. No natural motion can be carried to an extent fufficient to produce this effect; the tiffue of the axilla may be diftended three times as much as it is in the elevation of the arm, without any rupture. And this effect is ftill further prevented by the kind of locomotion which it admits; when forcibly drawn in any direction, it drags the neighbouring tiffue, and thus can change its fituation in fome degree. Thus, in large fwellings of the fcrotum, the cellular fubftance of the abdomen, perineum, and thighs, is brought over the part.

Inflammation entirely deftroys this property. In the induration accompanying cancerous affections the cellular tiffue is actually rendered very brittle.

The contractility of tiffue is obferved, when the caufes of extenfion ceafe to operate; as when a limb, after being extended, is reftored to its former pofition, when fat, ferum, or tumours are removed from the cellular fubftance, &c. If a wound be carried through the fkin and cellular membrane, the edges are feparated to a certain degree. This power exifts in its greateft energy in youth, and is gradually weakened as old age advances. When a young man is emaciated, the fkin is adapted clofely to the organs, and preferves its tenfion: in an old perfon, on the contrary, the integuments are loofe and flabby, becaufe the fubjacent tiffue does not contract.

2. *Vital Properties.*—This tiffue, in its ordinary ftate, does not poffefs animal fenfibility; it may be cut, torn, or diftended with gafes without caufing any pain, unlefs the nervous filaments paffing through it fhould be accidentally irritated. In difeafe, on the contrary, the fenfibility may be exalted to fuch a pitch, as to produce the moft acute pain; for example, in phlegmonous inflammation.

The organic properties are very ftrongly marked in this fyftem. The depofition and abforption of the fat and ferum are performed under their influence. All fubftances are not in the fame relation to the abforbing power. Blood, lymph, and milk, when introduced into the cellular fubftance, are taken up like the ferum or fat. On the contrary, urine, bile, faliva, and other fluids defigned to be expelled from the body, produce inflammation, and are not abforbed. Water and air artificially introduced are removed by the abforbents. Wine and other irritating fluids excite inflammation, and are expelled with the pus formed in confequence.

The cellular organ enjoys fenfible organic contractility to a certain degree: this is evidenced in the corrugation of the fcrotum from cold. It feems to be the firft obfcure rudiment of that power, which in a higher degree belongs to the mufcular fibres.

The fympathies of the cellular with other fyftems are very numerous, but cannot eafily be appreciated, on account of its being fo widely difseminated, and concurring in the ftructure of all the organs. In acute affections of a part, as the lungs, ftomach, &c. abfceffes often take place, and the critical fuppurations feem to be a fympathetic phenomenon. Œdema often comes on fuddenly in acute difeafes. But the influence of the principal vifcera on the cellular tiffue is particularly fhewn in the alterations of their ftructure confequent on chronic difeafe. The flow affections of the heart and lungs, of the liver, ftomach, fpleen, uterus, &c. are attended in their latter ftages by a more or lefs general anafarca. It feems now to be pretty generally agreed on, that the effufion in all thefe cafes is fymptomatic, and refults from the influence of the affected organ on the cellular tiffue. The very various conditions of the cellular fubftance in the dead fubject, may be probably referred to the effect of the particular difeafe which has proved fatal.

It alfo acts upon other parts, when it is originally affected. Phlegmonous abfceffes, when large, produce various affections of the brain, heart, liver, ftomach, &c.

It is clear, from the preceding obfervations, that the vital forces exift in a very marked degree in the cellular fyftem: in this refpect it is very different from the white organs, fuch as the aponeurofes, tendons, cartilages, ligaments, &c. among which it has been ranked, and which are remarkable for the obfcurity of their vital powers, and the flownefs of their functions. Inflammation paffes through its courfe with great rapidity in this fyftem, and the fluid, which refults from it, forms in its colour, confiftence, and other properties, the ftandard by which we judge all kinds of pus. Yet that which comes from a bone, a mufcle, a mucous membrane, &c. is equally good and *laudable* pus, as what is formed in a phlegmon.

Does the cellular tiffue affume any peculiar vital modifications in the organs, of which it enters into the compofition? This is not known.

However, thefe obfervations apply to it only in the intervals of parts, abftractedly from all combination of its ftructure with them.

We muft not pafs unnoticed the very marked difference between the generally diffufed tiffue made up of laminæ and filaments, and that modification, confifting only of the filamentous part, which furrounds mucous furfaces, blood-veffels, and excretory tubes: the latter is very feldom the feat of inflammation or tumours. It very often places a boundary to the affections of the former, and thus protects the organ which it includes. The tiffue furrounding the axillary or inguinal artery is often generally inflamed or ulcerated, and the veffel remains unaffected, &c.

The cellular tiffue is diftinguifhed from all others, by its reproductive properties, by its power of becoming elongated and growing, of forming what are called granulations, when it has been cut or divided in any way. Hence are explained the formation of cicatrices, tumours, cyfts, &c. The reparation of injury, therefore, is chiefly confided to this tiffue; and it goes on nearly alike in all parts, as all contain cellular fubftance: parts which have none of this never granulate.

Bichat ftates, that the granulations are fmall cellular veficles, filled with a thick fatty (lardacée) fubftance, and not admitting diftention by inflation of the furrounding tiffue. They are developed feparately and irregularly over the wound, unite at their bafes, and thus form a kind of provifional membrane, which completely protects the fubjacent parts from the contact of air, until the completion of cicatrifation. The furface of this is tuberculated, and it differs in that refpect only from a ferous membrane. This explanation

nation of the proceſs of cicatriſation is confirmed by various conſiderations. Granulations are formed moſt readily, and wounds are healed moſt quickly, where this ſyſtem is the moſt abundant; cicatriſation proceeds ſlowly where the cellular tiſſue has been extenſively removed. Maceration reduces all granulating ſurfaces to this common baſis. The nature of granulations is every where the ſame, whatever organ, whether muſcle, cartilage, ſkin, bone, ligament, &c. may have produced them. They muſt, therefore, be produced from a tiſſue common to all organs, and this is the cellular ſubſtance.

The red aſpect of granulations has led to the opinion, that they are a vaſcular expanſion; but the appearance admits of an eaſier ſolution. The cellular membrane is crowded with exhalent and abſorbent veſſels, into which the red blood paſſes under inflammation. As the granulations are cellular, and in a ſtate of inflammation, they exhibit the redneſs of phlegmon or eryſipelas, which depends, not upon the elongation of veſſels, but ſimply on the tranſmiſſion of red blood through thoſe which ordinarily carry white. Thus, when the inflammation is paſſed, the membrane reſumes its natural colour; and granulations, after the cicatrix is formed, are colourleſs, becauſe the coloured blood has ceaſed to permeate them. How can we ſuppoſe red veſſels to be generated in ſtructures where they have no primitive exiſtence? for tendons and cartilages granulate.

The proceſs of nature is completely analogous in repairing the injuries of internal organs, as bones, cartilages, muſcles, &c., where there is no exterior wound. The ends of a broken bone become inflamed, and covered with a cellular production. Theſe granulations form a ſecretory or rather an exhalant organ, and firſt ſeparate gelatine, which gives to the callus a cartilaginous nature, and afterwards calcareous phoſphat, by which the bone is completed. In other organs the granulations ſeparate in a ſimilar way the peculiar nutritive matter of the organ; and the proceſs does not ſeem to be at all different from that of ordinary nutrition. The granulations of an external wound exhale pus, which is excreted.

As ſuppuration proceeds, the white ſubſtance in the cells of the granulations is removed, the cells are contracted, the tubercular elevations diſappear, and are replaced by a thin and ſmooth ſurface. It is thin, becauſe the thickneſs of the granulations depended on the contents of the cells, which are now empty; and it is much leſs extenſive than the original pellicle, becauſe the contraction of the cells draws together in every direction the edges of the divided part. Thus the granular productions, which ſeemed to be ſo abundantly developed as amply to repair the loſs of ſubſtance in the part, are reduced to a thin ſtratum conſtituting the cicatrix, of a reddiſh colour ſo long as the exhalants are full of blood, and afterwards whitiſh.

Fungous excreſcences from wounds, and exuberant granulations of all kinds, are overgrowths of the cellular ſubſtance, exceeding the ordinary laws of cicatriſation, which cannot be completed ſo long as they continue. The developement of the cellular ſyſtem is remarkably exhibited in tumours. The funguſes of mucous membranes, as in the antrum, the mouth and uterus, polypi, and cancers, are all the produce of cellular tiſſue: that ſyſtem forms their baſis, on which a peculiar matter is depoſited. It conſtitutes in ſhort the general baſis, or nutritive parenchyma, of all tumours; the formation of which exhibits phenomena exactly analogous to thoſe of ordinary nutrition. All the organs of the body have the ſame parenchyma of nutrition, which is vaſcular and cellular; they differ in the nutritive matters depoſited in it. In the ſame way all tumours are cellular, and their diſtinctions are drawn from the matters ſeparated by that tiſſue, which differ according to the different modifications of its vital powers, produced by the morbid alterations, of which it is the ſeat.

Cyſts have their origin in the cellular ſubſtance. Of this we have a proof in the ſtriking ſimilarity which they bear to ſerous membranes, which are eſſentially cellular. This analogy prevails throughout their conformation, ſtructure, vital properties, functions, and diſeaſes.

Developement of the Cellular Tiſſue—In the early periods of conception the fœtus is a ſoft mucous maſs, apparently homogeneous, in which the cellular tiſſue ſeems to prevail almoſt excluſively. Almoſt entirely fluid at firſt, it afterwards has the conſiſtence of jelly, and then cellular ſubſtance is viſible. The abundance of fluid is the cauſe of its peculiar appearance in the early periods: this fluid is viſcous and unctuous, and prevents us from producing artificial emphyſema. Nothing can exceed the delicacy of the plates and filaments which compoſe the cellular texture at this time.

Some time before birth, and during the years that follow it, the cellular fluid is conſtantly decreaſing; the cells become more apparent, and the maſs of the ſyſtem diminiſhed, becauſe as the organs grow, their intervals are rendered narrower. Yet it predominates over the other ſyſtems for a long time; hence the roundneſs of form, the multiplicity and facility of movements in the child. The tiſſue is ſtill extremely fine.

The vital powers of the ſyſtem are ſtrongly marked at this age; granulations are produced more readily, and paſs through their periods more rapidly than at any other time; wounds are healed more quickly, and tumours are developed, and grow in a much ſhorter time; ſerous fluid is quickly removed from the cells.

The cellular tiſſue aſſumes a more denſe and ſtrong form in the adult, and is in ſmaller quantity in proportion to the organs; hence the prominences of the latter under the integuments, the energy of muſcular forms, &c. Its quantity ſeems to vary in the different temperaments; and to be greater in the female than in the male.

It becomes ſtill more compact and hard in the old ſubject; and contains leſs fluid; hence the dryneſs and rigidity of parts in old age, and the general diminution of bulk in the body. Its vital powers are diminiſhed, and it no longer maintains the ſkin cloſe upon the ſubjacent parts, but allows it to become folded. Bichat, Traité des Membranes; and his Anatomie Générale, tom. i.

MEMBRANE, *Nictitating*. See NICTITATING, and the preceding article.

MEMBRANES, in *Midwifery* and *Anatomy*, the coverings which ſurround the fœtus while it is contained in the uterus; they are three in number, the decidua, chorion, and amnios. See EMBRYO.

MEME. *Que eſt Meme.* See QUE.

MEMECYLON, in *Botany*, a name adopted from Dioſcorides, whoſe μεμαικυλα is a ſynonym for the fruit of the *Arbutus* or Strawberry-tree, his κομαρος; and ſeems to be derived from μαω, *to deſire, or long for*, in alluſion to the tempting appearance of thoſe berries. The Latin name of the ſame fruit, *unedo*, carries the idea a ſtep further, implying that nobody would be tempted to eat more than one, becauſe the flavour is by no means anſwerable to the appearance. Linnæus in his *Flora Zeylanica*, 57, firſt applied this name to the genus which now retains it, and which is of a ſhrubby and berry-bearing nature, but does not appear to have any other pretenſions to this denomination. Mitchell choſe it, with rather more propriety, but too late, for a ſmall American plant, allied to *Arbutus*, which, as *Memecylon* was already pre-occupied, Linnæus called EPIGÆA; ſee that

that article.—Linn. Gen. 191. Schreb. 258. Willd. Sp. Pl. v. 2. 347. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 355. Juss. 321. Lamarck Dict. v. 4. 88. Illustr. t. 284. Gærtn. t. 127 and t. 179.—Clafs and order, *Octandria Monogynia*. Nat. Ord. *Onagræ*, Juff. or rather *Myrti*.

Gen. Ch. *Cal.* Perianth fuperior, of one leaf, undivided, bell-fhaped, turbinate, entire, or obfoletely four-toothed, permanent; cup-like and fometimes furrowed within. *Cor.* Petals four, ovate, acute, equal, fpreading, inferted into the rim of the calyx. *Stam.* Filaments eight, erect, awl-fhaped, dilated and abrupt at the top; anthers fimple, of two diftinct lobes, attached to the edges of the dilated top of the filament. *Pift.* Germen inferior, turbinate, containing the rudiments of many feeds; ftyle awl-fhaped; ftigma fimple. *Peric.* Berry globofe, crowned with the cylindrical calyx, of one cell. *Seeds* one, two or three, convex.

Eff. Ch. Calyx fuperior, turbinate, nearly entire. Petals four. Anthers on the edge of the dilated fummit of the filaments. Berry crowned with the cylindrical calyx.

Obf. The corolla is faid to be monopetalous in Willdenow and Hort. Kew. which is an error of the prefs in Linn. Syft. Veg. ed. 10, 12, 13 and 14, contradicting the character of four petals, rightly given at the head of the clafs.

1. M. *capitellatum.* Ceylon Memecylon. Linn. Sp. Pl. 497. Lamarck. fig. 1. (M. foliis ovatis; Linn. Zeyl. 57. Cornus fylveftris, foliis croceum colorem tingentibus, flofculis ad foliorum alas globofis; Burm. Zeyl. 76. t. 30. Walikaha; Herm. Muf. Zeyl. 4. Kasjavo-maram; Rheede Hort. Mal. v. 5. 37. t. 19.)—Leaves elliptic-ovate, obtufe, on fhort ftalks. Umbels axillary, fomewhat compound, on flender ftalks, longer than thofe of the leaves. —Native of Ceylon, Malabar and the ifland of Mauritius. It is a moderate-fized *tree*, with many oppofite *branches*, knotty or tumid under each fubdivifion. Every part is perfectly deftitute of pubefcence, which, as far as we can difcover, is the cafe with the whole genus. *Leaves* on fhort thick *footftalks*, oppofite, ovate, fomewhat elliptical, and often roundifh, blunt and generally emarginate, entire, as in the whole genus, about an inch long or more, and half as broad, coriaceous, fingle-ribbed, without veins; their upper fide dark green and fhining; under paler, yellower and opaque. *Umbels* axillary, more or lefs compound, their common ftalk flender, obfcurely quadrangular, its fubdivifions partly racemofe, but always more or lefs umbellate. *Flowers* green with a purple tinge in the petals. Tops of the *filaments* very broad. *Calyx* very flightly four-cleft, obtufe. *Style* thick, but twice the length of the calyx.

This is faid by Hermann to fupply the place of Saffron, in Ceylon, for dyeing. Linnæus confounded fo many fpecies under this one, at different times, that it is hard to fay exactly which he really meant. Our's is the plant of Burmann, and of the generality of botanifts, though not of the Linnæan herbarium. But in the prefent cafe the latter is of no authority, the fpecimen having been acquired after the publication of the *Species Plantarum*, and not even marked with any trivial name.

2. M. *ramiflorum.* Naked-flowering Memecylon. Lamarck. Dict. v. 4. 88. (M. tinctorium; Willd. Sp. Pl. v. 2. 347. Koen. MSS. Cornus zeylanica fylveftris altera, *korakaha* dicta; Burm. Zeyl. 76. t. 31. Korakaha; Herm. Muf. Zeyl. 40.)—Leaves elliptical, obtufe, on fhortifh ftalks, deciduous. Umbels from the defoliated part of the branches, aggregate, compound, ftalked. Style capillary, four times as long as the petals.—Native of Ceylon, and other parts of the Eaft Indies. Very like the laft, except that the *leaves* are rather more oblong, *flowers* much more copious, from the leaflefs part of the branches, and effentially diftinguifhed by the great length, and flendernefs, of their *ftyle.* We cannot comply with Willdenow's change of Lamarck's moft excellent name, for an unpublifhed one of Koenig's, which is at leaft as fuitable to the firft fpecies, if not to every other. We have no doubt of Burmann's fynonym, though he defcribes but four ftamens; as he commits the fame error refpecting the foregoing.

3. M. *ovatum.* Ovate Memecylon.—Leaves ovate, bluntly pointed, veiny, on longifh ftalks, deciduous. Umbels from the defoliated part of the branches, aggregate, ftalked. Style thread-fhaped, four times as long as the petals. —Native of the Eaft Indies? It lies in the Linnæan herbarium for *Santalum album;* but the fpecimen is not an original one, and the real *Santalum album* is no other than *Sirium myrtifolium* of Linnæus; fee Roxb. Coromand. v. 1. t. 2. The prefent fpecies differs widely from the laft in appearance, though nearly agreeing with it in feveral effential characters. The *footftalks* are above half an inch long; *leaves* near three inches, exactly ovate, with an elongated bluntifh point; their upper fide marked with many tranfverfe parallel veins. *Flowers* fmall, numerous, with a very long ftyle. The bottom of their *calyx*, above the *germen*, has eight elevated ribs, making as many furrows, which we find alfo in moft of the fpecies, as defcribed by Linnæus.

4. M. *acuminatum.* Pointed Memecylon.—Leaves on fhort ftalks, elliptical, pointed. Umbels axillary, ftalked, in pairs, fimple. Style about the length of the petals. We find a fpecimen of this, without name, or mention of its native country, in the herbarium of the younger Linnæus. Its *leaves* agree in fize with the laft, but are elliptical, tapering at each end, with a longifh acute point, and no perceptible veins; their *footftalks* very fhort and thick. *Umbels* fmall and fimple, axillary, and not from the naked parts of the branches, ufually in pairs, each umbel of four or five flowers. *Style* rather above half the length of the former, ftraight.

5. M. *edule.* Eatable Memecylon. Roxb. Coromand. v. 1. 59. t. 82.—Leaves on fhort ftalks, ovate, acute, veiny, deciduous. Umbels from the defoliated part of the branches, aggregate, ftalked. Style the length of the petals.—Very common in every thicket on the coaft of Coromandel, flowering in the beginning of the hot feafon. A fmall *tree*, with numerous *branches*. *Leaves* moft like thofe of the third fpecies, but lefs pointed, and on fhorter ftalks. *Flowers* purple, much like thofe of that fpecies, except that Dr. Roxburgh reprefents the *ftyle* as not longer than the *petals*. *Berries* the fize of a black currant, purple, juicy, aftringent, eaten by the natives, who call the plant *Alie*. The *calyx* is drawn with four very diftinct lobes. We have feen no fpecimen, and much fufpect this plant may be the fame with our *ovatum*, n. 3; but as we find reafon to prefume the exiftence of more fpecies than we have feen in fufficient perfection to define them, we think it beft to keep thefe feparate.

The fpecimen mentioned under the firft fpecies, as preferved in the Linnæan herbarium, very clofely refembles Roxburgh's figure, as to *leaves* and *footftalks*, but the *flowers* are much larger, fewer, on thicker fhorter ftalks, and axillary. It is marked *Tamba lifa*, which we believe is a Malay name. Our materials are fcarcely fufficient to diftinguifh this plant fpecifically from the *edule*. It is however moft indubitably different from our *ovatum* and *acuminatum*.

6. M. *grande.* Large-leaved Memecylon. Retz. Obf. fafc. 4. 26. Willd. n. 3. (Nedum Schetti; Rheede Hort. Malab. v. 2. 21. t. 15?)—Leaves feffile, ovate, long-pointed. Flowers in denfe, axillary, forked clufters.—

Sent

Sent by Mr. Christopher Smith from Malacca. The *branches* are round, knotty, smooth; purplish when young. *Leaves* nearly or quite sessile, crowded, four inches or more in length, one inch and a half wide, ovate at the base, tapering to a bluntish point, scarcely marked with any transverse veins; their substance very thick and coriaceous. *Flowers* larger than in any of the foregoing, purplish, in thick, dense, globose, axillary clusters. *Calyx* very obscurely four-toothed. Of the proportion of the *style* we cannot judge. The plant of the *Hortus Malabaricus* seems, by the description, to be this; but if so, the *flowers* are very badly drawn. We have seen no specimen from Koenig or Retzius, but we presume our plant to be the same as their's by the description.

7. M. *cordatum*. Heart-leaved Memecylon. Lamarck Dict. v. 4. 89. fig. 2. Willd. n. 4.—Leaves sessile, heart-shaped, bluntish. Umbels axillary, stalked, compound.—Brought by Commerson from the isle of Bourbon, where it is called *Bois de Mays*. There is a specimen in sir J. Banks's herbarium, gathered in the Mauritius, by Aublet, who describes it as a tall and handsome *tree*, with a grey bark. The *leaves* of Commerson's specimen before us are from one to two inches long, and one broad, obscurely veiny, more or less heart-shaped at the base. *Inflorescence* very different from the last, consisting of no great number of *flowers*, in a variously divided umbel, on a slender stalk, full half an inch long. *Calyx* much less distinctly four-cleft than in Lamarck's figure.

MEMEL, in *Geography*, a town of Prussian Lithuania, situated on the bay called "Curisch-Haff." On one side it has the Baltic; and on the other the Curisch-Haff; and it is also watered by the river Dange. Its harbour is deep, and has a good entrance, and has, not long ago, been improved by two moles, which extend above 50 rods into the Haff or bay. Memel lies under the guns of the fort, and is well inhabited, the number of houses being above 400. It has a German, Lithuanian, and Calvinist church. The burghers, who are divided into those of Altstadt, or the Old Town, and Frederickstadt, are employed in commerce, brewing, soap-boiling, agriculture, fishing, &c. Great quantities of flax, linseed, thread, and hemp, are annually exported from this town. It is well-fortified, and was formerly one of the Hanse towns; and it has now the establishments of a royal magazine, a salt-factory, and a post-office of considerable revenue; 72 miles N.N.E. of Königsberg. N. lat. 55° 50'. E. long. 21° 25'.

MEMENE, a town of the island of Ceylon, near the E. coast; 86 miles E.S.E. of Candi.

MEMINISCA, a lake of Canada. N. lat. 52° 20'. W. long. 88° 50'.

MEMMINGEN, a town of Bavaria, on the Iller; which was imperial till the year 1804, when it was transferred, among other indemnities, to the elector of Bavaria. The inhabitants are chiefly Lutherans, but the principal church is possessed by them in common with the Roman Catholics. This town carries on a good trade with Switzerland, Italy, and other adjacent countries, in Bavarian salt, home-spun linen, hops, grain, and other goods. In 1805, it was taken by the French; 22 miles S.S.E. of Ulm. N. lat. 48° 3'. E. long. 10° 7'.

MEMNON, in *Biography*, a native of Rhodes, was a general in the service of the last Persian king, Darius, whom he served, with great fidelity, against Alexander the Great. When that conqueror had landed in Asia, and was advancing up the country, Memnon advised him not to hazard a battle, but to lay waste the country before the invader. His counsel was rejected, and the battle of the Granicus, in the year 334 B.C. followed, in which Memnon, at the head of the Greek mercenaries, displayed the greatest valour. After the defeat, he obtained, by his valour, the most honourable conditions, and was almost immediately after created the high admiral of Darius, and governor of the Lower Asia. He had now the important command of the city of Halicarnassus, when it was besieged by Alexander, and employed every effort in his power to save it. The siege was continued a long time, and great numbers of the Macedonians lost their lives before the place. Memnon was generous as well as courageous, for when the fugitive Greek commanders, through hatred of Alexander, opposed the demand from the Macedonians of permission to bury their dead, he would not listen to their remonstrances, alleging that it was unworthy of a Greek to refuse the rites of burial even to an enemy. And hearing one of his soldiers abusing Alexander in gross and vulgar terms, he struck him with his javelin, saying "I hired you to fight Alexander, not to revile him." When he found the place no longer tenable, he threw a strong garrison into the citadel, and with his troops, and the inhabitants with their effects, embarked for the island of Cos. He then advised Darius to make a powerful diversion into Macedonia, as the only means of saving himself from destruction. Darius gave him full power to levy troops, and he exerted himself with so much vigour, that he reduced several of the Cyclades, and the islands of Chios and Lesbos, excepting Mitylene, the capital of the latter. While carrying on a siege against that city he died, and thus freed Alexander from the only foe of whom he stood in awe. Memnon had married Barsine, a Persian lady of high rank, who, with her children, remained at the court of Darius some time, till at length she fell under the power of the conqueror, who took her to his bed, and had a son by her. Univer. Hist.

MEMNON, a Greek historian, is thought to have flourished in the time of Augustus. He wrote a history of the affairs of Heraclea in Pontus, sixteen books of which were abridged by Photius. They came down to the death of an Heraclean ambassador to Julius Cæsar, then emperor. A Latin translation of his history was published at Oxford in 1597.

MEMNON, *Statue of*, a colossal figure of gigantic size, formed of very hard granite, which was found in a mutilated state, and lying on the earth, among the ruins of Thebes in Egypt. Diodorus Siculus (lib. i.) calls it Osimandué; Strabo says (lib. xvii.), that it was called by the Egyptians Ismandes; but writers in general give it the name of Memnon. This colossus, according to Philostratus, represented a young man in the flower of his age, whose face was turned towards the rising sun; and when the solar rays fell upon it, it was said to speak, or to utter harmonious sounds. Strabo says, that he had been witness to this pretended miracle, which can be attributed to nothing but either the quality of the stone of which it was made, or to the imposture of the priests, or rather to some secret spring, which the learned Kircher, after Pausanias, (in Attic.) alleges to have been a kind of harpsichord inclosed within the statue, whose strings being first slackened by the moisture of the night, and then distended by the heat of the sun, broke with a noise resembling that of the string of a violin when it breaks. Cambyses, who spared not the Egyptian ox Apis, having a mind to disclose this mystery, in which he suspected some trick of magic, broke the statue from the head to the middle of the body. Strabo, in his account of this statue, reports, that he and some friends, whilst they were surveying it, heard a certain sound, without being able to determine whether it came from the statue, or the base, or if it proceeded from any of the by-standers; for, he adds,

I would

I would rather believe any thing elfe, than imagine that ftones ranged in fuch and fuch a manner were capable of yielding fuch a found. Paufanias informs us, that in his travels through Egypt, he faw the remains of this ftatue, which Cambyfes had broke. The lower part of the coloffus, he fays, was ftill upon its pedeftal, but the reft of the body was thrown down to the ground, and every morning at the fun rifing yielded the found already mentioned. Pliny and Tacitus advance the fame fact, but without having been witneffes to it: and Lucian informs us, that Demetrius went on purpofe to Egypt, to fee there the pyramids, and Memnon's ftatue, from which a voice proceeded at the rifing of the fun. Of the fact that this ftatue uttered founds, when the fun fhone upon it, there can be no doubt; nor can it be difficult to account for the phenomenon. The priefts of Thebes might have carried the mechanic art to fuch a degree of perfection as to be able to fabricate a fpeaking head, the fprings of which were fo arranged, that it fhould pronounce founds at the rifing of the fun. Cambyfes deftroyed this wonderful mechanifm, by overturning the upper part of the ftatue; and all the teftimonies that are cited to the fact refer only to the trunk, which is now feen upon the pedeftal. It is natural, therefore, to attribute the found of the mutilated coloffus to the artifices of the priefts, who oppofed this pretended miracle to the rife and progrefs of Chriftianity. Lucian in particular would have been glad to have availed himfelf of a phenomenon, which he fpeaks of with raillery, in this view of it. At all events, it is very certain, that fince the commencement of the fourth century of the church, when the inhabitants of Egypt became Chriftians, no more has been faid of the vocal ftatue, firft called Memnon by Herodotus, but in the chronicle of Alexandria, and by the Egyptians themfelves, Amenophis. In reply to thofe who inquire concerning the object which the priefts had in view in framing this vocal ftatue, it has been faid that they were in the habit of confecrating their fecondary deities to the prefervation of the records of their moft important difcoveries. Amenophis was formed with the fame intention. To this purpofe the ancients and Jablonfki (De Memnon.) who has collected their teftimonies with extreme attention, affure us that the feven vowels were confecrated to the feven planets, and that the ftatue of Amenophis repeated them at a certain epocha. Lucian introduces Eucrates on the ftage, and makes him fay, "In Egypt I have heard Memnon utter, not according to cuftom, an infignificant found, but pronounce from his mouth an oracle in feven founds." This paffage, probably, is a mere pleafantry of Lucian, but it is founded on the general perfuafion, that before Cambyfes broke this coloffus, it pronounced the feven vowels. The Egyptians, as we learn from Macrobius (Somn. Scip.) regarded the fpring equinox as the era of the creation, and to this period the attention of the learned and of the people was chiefly directed. Amoun, a fymbolical divinity, was confecrated to it, and all the feftivals they celebrated in his honour, related merely to this interefting period. It was at this period the aftronomical year commenced; and from hence, according to the priefts, the feven planets renewed their courfe, which they allegorically ftyled the celeftial mufic. It was at this moment alfo that Amenophis pronounced the feven vowels which were the fymbols of the planets, and which compofed the terreftrial mufic. This famous ftatue may be called in facred language the coufin of Ofiris (Diod. Sic.) and the image of the fun, fince it imitated on earth the office which this luminary performed in the heavens. The priefts by making him repeat the feven founds, of which all languages are formed, and which wonderfully paint our thoughts, were defirous of immortalizing the moft beautiful of their difcoveries; a difcovery which, according to Plato, could only be invented by a god, or by a divine mortal. Perhaps, alfo, the fhadow of this lofty coloffus ferved to mark the inftant of the equinox. Its name at leaft compofed of "Ame Nouphi," to tell good tidings, intimates fomewhat of the kind, more efpecially when we confider that the fun, when he arrived at the equator, in his annual courfe, promifed the Egyptians a ceffation of the foutherly winds, and the approach of the inundation, which made it an object of anxious attention.

There is no lefs variety of opinion among both ancients and moderns, concerning Memnon himfelf, than in relation to his ftatue. Upon the authority of Hefiod, who faid that he was king of Thebes, the fucceeding Greek authors adopted this opinion. Paufanias, Strabo, Diodorus mention it, and alfo Pindar and Ovid. M. Le Clerc has a fingular opinion concerning this prince; he takes him for Hammon, or Ham, the fon of Noah; and Voffius afferts that he was the fame with Baaltis, a divinity of the Syrians, male and female, called by the Greeks *Aphrodité*, and reprefented under the form of a ftone. Diodorus Siculus ftates, "that this prince, the fon of Tithonus, led to Troy the Affyrian troops, under the reign of Teutamus, who was the 20th king from Ninus and Semiramis; the Affyrians at that time, *i. e.* more than a thoufand years ago, poffeffing the empire of Afia; Priam, who was tributary to the kingdom of Teutamus, having applied to him for affiftance in his preffing exigency, and having fent to him, under the conduct of Memnon, 10,000 Affyrians, and as many Perfians, with 200 chariots." We fhall clofe this article with a paffage from the learned Huetius's Treatife concerning the Terreftrial Paradife (ch. 13.) which throws more light upon the hiftory of Memnon than any thing that had been before faid of him. "Memnon," fays that learned prelate, "was the fon of Tithonus and Aurora. Tithonus was the brother of Priam king of Troy, and to him is fometimes afcribed the founding of the city Sufa, the capital of Sufiana. From the name of Memnon his fon, the citadel was denominated Memnonium, the palace and the walls Memnonian, and Sufa itfelf the city of Memnon, upon account of the veneration that was paid to him there; and in honour of him a temple was built, whither the Affyrians went and mourned for him, which is to be underftood of the people of Sufiana. This is that Memnon who came to the affiftance of the Trojans, from whom he derived his original, and who was flain by Achilles. When the Greeks feigned that he was the fon of Aurora, they would have us to underftand that he came from the eaft.—I know the hiftory of Memnon is very perplexed, and very differently related. Moft ancient authors tell us he was an Ethiopian; this error flows from their confounding Chus, which fignifies Sufiana, with Chus which fignifies the countries fituated upon the borders of the Arabic gulf, I mean Ethiopia and Arabia.—What we are in reafon to think concerning Memnon's expedition, may be gathered from Diodorus, and fome others. The kingdom of Troas was in the dependence of the empire of Affyria. Tithonus, Priam's brother, who was mafter of that kingdom, went to the court of the king of Affyria, who gave him the government of Sufiana. There he married in his old age; and becaufe his wife was from a country fituated to the eaft of Greece and Troas, the Greeks, who turned all hiftory into fiction, faid he had married the Morning. Memnon and Emathion were the iffue of this marriage: the war having after this arifen, Priam applied to Teutamus for affiftance, or at leaft to fome king of Affyria, who granted him twenty thoufand men, and two hundred chariots of war. Diodorus fays this fupply confifted of ten thoufand Ethiopians, and ten thoufand thousand Susians, returning to the vulgar error, and confounding the Chus of Ethiopia with the Chus of Susiana. To make this supply of more service, Teutamus gave the command thereof to Memnon, a young prince of the Trojan race, and who was therefore concerned for the preservation of Troy. He kept Tithonus with himself upon account of his age, which rendered him unfit for the expedition, and his prudence which qualified him for being member of his council. Memnon found resistance in his march. The Solymi, who have been since called the Pisidians, would needs dispute the passage with him; but he defeated them and all that opposed him. He cleared the passes, repaired the ways, and by reason of that long and dangerous march, had the honour to communicate his name to that high way which was denominated Memnonian. He sustained the attacks of the Greeks before Troy with great valour; but at last was slain by Achilles. Various accounts are given of the place of his burial; for not to mention Philostratus, who will have it that he had no sepulchre, but that he was transformed into that miraculous stone, Troas, Phœnicia, and Susiana contended together for him, and especially Ethiopia, though it has no other right to his burial any more than to his birth, but that which arises from the equivocation of the word Chus. But notwithstanding the obscurity that this equivocation has cast upon this history, Philostratus, George Syncellus, that is, the coadjutor to the church of Constantinople, and Suidas who had read and copied good authors, though often not very judiciously, have not been wanting to bear testimony to the truth; the first telling us that Memnon the Ethiopian, that is Amenophis, never came from Troy, and that he was wrongfully confounded with Memnon the Trojan, not comprehending how Memnon could have brought supply to the Trojans from so great a distance, nor even by what adventure Tithonus had gone and settled in Ethiopia, and came to be king thereof; the second, by distinguishing exactly Amenophis king of Thebes in Egypt, who is also stiled Memnon, from the speaking statue of Memnon the son of Tithonus, whom he ranks among the kings of Assyria; and Suidas, by asserting that that Memnon was not an Ethiopian, but a Susian. Pausanias, though of a very penetrating genius, has but half unravelled this confusion; saying that Memnon the Ethiopian came not from Ethiopia to Troy, but from Susa. Eustathius, and the scholiast on Pindar, who goes by the name of Triclinius, write that Memnon and Emathion his brother were the only white men among those Ethiopians, though Virgil and others make Memnon black. This remark confirms my opinion; for though the poets and writers of romance have taken the liberty to feign that Andromeda and Charicleus were born white among the blacks, yet this is so singular in the ordinary course of nature, that there is much more reason to believe that Memnon was white, because in fact he was not an Ethiopian."

MEMOIRS, or Memorials, a term now much in use for histories composed by persons who had some share or concern in the transactions they relate, or who were eye-witnesses of them; answering to what the Latins called *commentarii*.

The French are great dealers in this way of writing, and have an infinite number of books of memoirs, containing, for the generality, the lives, actions, intrigues, amours, &c. of the writers.

Memoirs also denote a journal of the acts and proceedings of a society; or a collection of the matters debated, transacted, &c. therein. Such are the Memoirs of the Royal Academy of Sciences, &c.

MEMORY, *μνημη*, a power or faculty of the mind, which receives, retains, and exhibits again, as occasion requires, all sorts of ideas presented to the understanding.

Of all the faculties, there is none harder to account for, or that has perplexed philosophers more, than the memory. Some will have it a mere organ, as the eye, ear, &c. Dr. Hooke, in an "Essay towards a mechanical Account of Memory," makes it to consist in a stock of ideas or images, formed occasionally by the mind, out of the fine parts of the brain, and disposed or laid by in order.

Descartes and his followers maintain, that the animal spirits, exciting a motion in the most delicate fibres of the brain, leave a kind of traces or footsteps, which occasion our *remembrance*. Hence it happens, that by passing several times over the same things, the spirits becoming accustomed to the same passages, leave them open, and so make their way without any effort or labour; and in this consists the ease wherewith we recollect such ideas. Thus wine is found to sharpen the memory, because wine puts the animal spirits in motion, and agitates the fibres of the brain more briskly.

Father Malebranche expresses his notion of memory thus: "It being granted, that all our different perceptions are owing to changes happening in the fibres of the principal part of the brain, wherein the soul more immediately resides, the nature of the memory is obvious: for as the leaves of a tree, that have been folded for some time in a certain manner, preserve a facility of disposition to be folded again in the same manner; so the fibres of the brain, having once received certain impressions by the courses of the animal spirits, and by the action of objects, preserve, for some time, a facility to receive the same disposition. Now it is in this facility that memory consists; for we think the same things, when the brain receives the same impressions.

"Farther, as the animal spirits act sometimes more briskly, and sometimes more languidly, on the substance of the brain; and as sensible objects make much deeper, and more lasting impressions, than the imagination alone; it is easy, on this scheme, to conceive why we do not remember all things alike; why a thing, for instance, seen twice, is represented more vividly to the mind than another seen but once: and why things that have been seen, are usually remembered more distinctly, than those that have been only imagined, &c.

"Old men are defective in memory, and cannot learn any thing without much difficulty, because they want animal spirits to make new traces, and because the fibres of the brain are become too hard to receive, or too moist to retain, such impressions. For the same reason, those who learn with the greatest ease forget the soonest; in regard when the fibres are soft and flexible, objects make a slight impression, which the continual course of animal spirits easily wears off. On the contrary, the fibres of those who learn slowly, being less flexible, and less subject to be shaken, the traces are more deeply engraven, and last the longer. From all which observations it follows, that the memory is absolutely dependent on the body; being impaired or strengthened, according to the changes that befal the body; a fall, the transports of a fever, &c. being frequently found to erase or blot out all the traces, to bear away all the ideas, and to cause an universal forgetfulness."

The chief difficulty that embarrasses this doctrine of memory is to conceive how such an infinite number of things, as the head is stored with, should be ranged in so much order in the memory, as that the one should not efface the other; and how, in such a prodigious assemblage of traces impressed on on the brain, the animal ſpirits ſhould awake preciſely thoſe which the mind has occaſion for.

Memory, according to Mr. Locke, is, as it were, the ſtorehouſe of our ideas. For the narrow mind of man not being capable of having many ideas under view and conſideration at once, it was neceſſary to have a repoſitory, in which to lay up thoſe ideas which it may afterwards have uſe for. But our ideas being nothing but actual perceptions in the mind, which ceaſe to be any thing when there is no perception of them; this laying up of our ideas in the repoſitory of the memory, ſignifies no more than this, that the mind has a power, in many caſes, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the aſſiſtance of this faculty, that we are ſaid to have all thoſe ideas in our underſtandings, which we can bring in ſight, and make the objects of our thoughts, without the help of thoſe ſenſible qualities which firſt imprinted them there.

Attention and repetition help much to the fixing of ideas in our memories: but thoſe which make the deepeſt and moſt laſting impreſſions, are thoſe which are accompanied with pleaſure and pain. Ideas but once taken in and never again repeated, are ſoon loſt; and thoſe of colours in ſuch as loſt their ſight when very young.

The memory of ſome men is tenacious even to a miracle; but yet there ſeems to be a conſtant decay of all our ideas, even of thoſe which are ſtruck deepeſt, and in minds the moſt retentive; ſo that if they be not ſometimes renewed, the print wears out, and at laſt there remains nothing to be ſeen.

Thoſe ideas that are often refreſhed by a frequent return of the objects or actions that produce them, fix themſelves beſt in the memory, and remain longeſt there: ſuch are the original qualities of bodies, *viz.* ſolidity, extenſion, figure, motion, &c. and thoſe that almoſt conſtantly affect us, as heat and cold.

In memory, the mind is oftentimes more than barely paſſive; for it often ſets itſelf to work to ſearch ſome hidden ideas; ſometimes they ſtart of their own accord; and ſometimes tempeſtuous paſſions tumble them out of their cells. This faculty other animals ſeem to have to a great degree, as well as men, as appears by birds learning of tunes, and their endeavours to hit the notes right. For it ſeems impoſſible that they ſhould endeavour to conform their voices (as it is plain they do) to notes whereof they have no idea. Eſſay concerning Hum. Und. book ii. chap. 10.

Dr. Hartley, agreeably to his mechanical theory of the human mind, defines memory to be that faculty by which traces of ſenſations and ideas recur, or are recalled, in the ſame order and proportion, accurately or nearly, as they were once preſented: and he obſerves, that memory depends entirely or chiefly on the ſtate of the brain, which is peculiarly conformable to his notion of vibrations. The rudiments of memory, he ſays, are laid in the perpetual recurrency of the ſame impreſſions, and cluſters of impreſſions: and thus he endeavours to account for the peculiar imperfections of the memory in children and aged perſons, as well as for other facts pertaining to the exerciſe of this faculty. Obſ. on Man, vol. i. p. 374, &c.

Thoſe who adopt Hartley's theory enumerate among other phenomena of memory ſuch as the following: ideas of recollection are diſtinguiſhed from ſenſations, chiefly by a difference in the vividneſs of the impreſſions, ſo that when from diſeaſe, or any cauſe, ideas become as vivid as ſenſations, they are miſtaken for ſenſations, as in phrenſy; and alſo by the aſſociates which accompany them. Ideas of memory are diſtinguiſhed from reveries, chiefly by the readineſs and ſtrength of the aſſociations by which they are cemented together; and recollected ideas are alſo diſtinguiſhed from reveries by their connection with known facts, and by various methods of reaſoning. Memory, it is alſo ſaid, depends entirely or chiefly on the ſtate of the brain. Hence diſeaſes, concuſſions of the brain, and ſpirituous liquors impair it; and it generally returns again with the return of health. Memory alſo differs in different ages, inſomuch that children ſoon learn and ſoon forget; old people learn with difficulty, and remember beſt what they learned when young; and this, it is alleged, is agreeable to the theory of vibrations. Senſations, attended with great pleaſure or pain, make a deep impreſſion on the memory, which is probably owing to the vigorous vibrations which they excite. Senſible ideas gradually decay in the memory, if not refreſhed by new ſenſations. Voluntary recollection is performed by calling up aſſociated ideas, which by degrees introduce the idea in queſtion. Some perſons of weak judgment poſſeſs retentive memories; but there are limits beyond which the two powers of receiving and of retaining ideas cannot conſiſt with each other. Memory is a faculty inceſſantly exerciſed while thought continues; nor is the mind wholly deprived of it, though it is often much impaired. The excellence of memory conſiſts partly in its ſtrength of retention, and partly in the quickneſs of recollection. All the faculties of the mind are dependent on the memory: and though ſome perſons may have ſtrong memories with weak judgment, no perſon can have a ſtrong judgment whoſe memory is remarkably defective.

It is commonly ſuppoſed, ſays profeſſor Dugald Stewart, (*ubi infra*) that genius is ſeldom united with a very tenacious memory. "So far, however," ſays this ingenious writer, "as my own obſervation has reached, I can ſcarcely recollect one perſon who poſſeſſes the former of theſe qualities, without a more than ordinary ſhare of the latter. On a ſuperficial view of the ſubject, indeed, the common opinion has ſome appearance of truth; for we are naturally led, in conſequence of the topics about which converſation is uſually employed, to eſtimate the extent of memory by the impreſſion which trivial occurrences make upon it; and theſe in general eſcape the recollection of a man of ability, not becauſe he is unable to retain them, but becauſe he does not attend to them. It is probable, likewiſe, that accidental aſſociations, founded on contiguity in time and place, may make but a ſlight impreſſion on his mind. But it does not therefore follow, that his ſtock of facts is ſmall. They are connected together in his memory by principles of aſſociation, different from thoſe which prevail in ordinary minds, and they are on that very account the more uſeful; for as the aſſociations are founded upon real connections among the ideas, (although they may be leſs conducive to the fluency, and perhaps to the wit of converſation,) they are of incomparably greater uſe in ſuggeſting facts which are to ſerve as a foundation for reaſoning or invention."—"Montaigne frequently complains in his writings of his want of memory: and he indeed gives many very extraordinary inſtances of his ignorance in ſome of the moſt ordinary topics of information. But it is obvious to any one who reads his works with attention, that this ignorance did not proceed from an original defect of memory, but from the ſingular or whimſical direction which his curioſity had taken at an early period of life."—"I can do nothing," ſays he, "without my memorandum book; and ſo great is my difficulty in remembering proper names, that I am forced to

call

call my domestic servants by their offices. I am ignorant of the greater part of our coins in use: of the difference of one grain from another, both in the earth and in the granary: what use leaven is of in making bread, and why wine must stand some time in the vat before it ferments."—" Yet the same author appears evidently, from his writings, to have had his memory stored with an infinite variety of apophthegms and of historical passages, which had struck his imagination: and to have been familiarly acquainted, not only with the names, but with the absurd and exploded opinions of the ancient philosophers." The foregoing observations serve to account, in part, for the origin of the common opinion, that genius and memory are seldom united in great degrees in the same person; and it also appears, that some of the facts, on which that opinion is founded, do not justify such a conclusion. There are, however, other circumstances, that seem rather to indicate an inconsistency between extensive memory and original genius. "The species of memory which excites the greatest degree of admiration in the ordinary intercourse of society, is a memory for detached and insulated facts; and it is certain that those men who are possessed of it, are very seldom distinguished by the higher gifts of the mind, and such a species of memory is unfavourable to philosophical arrangement; because it in part supplies the place of arrangement." Dr. Pemberton informs us, that sir Isaac Newton was often at a loss when the conversation turned on his own discoveries: they probably made but a slight impression on his mind, and a consciousness of his inventive powers prevented him from taking much pains to treasure them up in his memory. He nevertheless, as Dr. Pemberton says, perfectly understood his own writings, though his memory was much decayed in the last years of his life. (See Preface to Pemberton's View of Newton's Philosophy.) "A man of original genius," says professor Stewart, "who is fond of exercising his reasoning powers anew on every point as it occurs to him, and who cannot submit to rehearse the ideas of others, or to repeat by rote the conclusions which he has deduced from previous reflexion, often appears to superficial observers to fall below the level of ordinary understandings; while another, destitute both of quickness and invention, is admired for that promptitude in his decisions, which arises from the inferiority of his intellectual abilities." Here we cannot forbear citing one of the aphorisms of lord Bacon: "Reading makes a full man, writing a correct man, and speaking a ready man." See also on this subject Watts's Improvement of the Mind, chap. xvii. or Works, vol. v. p. 275, &c.

Memory is a source of refined and permanent pleasure: painful recollections gradually subside within the limits of pleasure: and if time sufficient be allowed, by the power of association, all pain will be ultimately absorbed, and the pleasures of memory will be pure and unmixed with misery. See Rogers's Pleasures of Memory.

Memory, according to Dr. Reid, is an original faculty given us by the author of our being, of which we can give no account, but that we are so made. I believe most firmly, says this author, what I distinctly remember; but I can give no reason of this belief. It is the inspiration of the Almighty that gives me this understanding. Memory, he says, is always accompanied with the belief of that which we remember; and this belief we account real knowledge, no less certain than if it was grounded on demonstration. The testimony of witnesses, in causes of life and death, depends upon it, and all the knowledge of mankind, with regard to past events, is built on this foundation. Reid's Essays on the Intellectual Powers of Man, Ess. iii. ch. 1, 2. 7.

The word memory, says professor Dugald Stewart, is not employed uniformly in the same sense: it is sometimes employed to express the capacity of retaining knowledge, and sometimes the power of recalling it to our thoughts, when we have occasion to apply it to use. When we speak of a retentive memory, we use it in the former sense; when of a ready memory, in the latter. The various particulars which compose our stock of knowledge sometimes recur to us spontaneously, or at least without any interference on our part; in other cases, they are recalled by an effort of our will. The former operation of the mind is denoted by Memory; the latter, though sometimes called by the same name, is more properly distinguished by the word Recollection. The operations of memory relate either to things and their relations, or to events. In the former case, thoughts which have been previously in the mind may recur to us, without suggesting the idea of the past, or of any modification of time whatever, as when I repeat over a poem which I have got by heart, or when I think of the features of an absent friend. In these cases, the operations of memory do not necessarily involve the idea of the past. But when I think of events, I not only recal to the mind the former objects of its thoughts, but I refer the event to a particular point of time; so that of every such act of memory, the idea of the past is a necessary concomitant. If it be inquired, to what it is owing that the memory retains some things in preference to others? our author replies, that this may be ascribed to two principles of our nature, upon which memory is dependent, and with which it is very intimately connected; these are *attention* and the *association* of ideas. Without attention, even the objects of our perceptions make no impression on the memory. (See Bacon, Nov. Org. lib. ii. aphor. 6.) This attention, though it be a voluntary act, requires experience to have it always under command. In the case of objects to which we have been taught to attend at an early period of life, or which are calculated to rouse the curiosity, or to affect any of our passions, the attention fixes itself upon them, as it were, spontaneously, and without any effort on our part, of which we are conscious. On the other hand, if an object does not interest some principle of our nature, we may examine it again and again, with a wish to treasure up the knowledge of it in the mind, without our being able to command that degree of attention which may lead us to recognise it the next time we see it. By this kind of reasoning we can account for a well-known fact, that objects are easily remembered which affect any of the passions. The passion assists the memory, not in consequence of any immediate connection between them, but as it presents, during the time it continues, a steady and exclusive object to the attention.

Our ingenious author proceeds to state the connection between memory and the association of ideas. This, he says, is so striking, as to have induced some to suppose, that the whole of its phenomena might be resolved into this principle. This the professor does not allow. "The association of ideas connects our thoughts with each other, so as to present them to the mind in a certain order; but it presupposes the existence of these thoughts in the mind; or, in other words, it presupposes a faculty of retaining the knowledge which we acquire. It involves also a power of recognizing, as former objects of attention, the thoughts that from time to time occur to us; a power which is not implied in that law of our nature, which is called the association of ideas."—"On the other hand, it is evident that, without the associating principle, the power of retaining our thoughts, and of recognizing them when they occur to us, would have been

been of little uſe; for the moſt important articles of our knowledge might have remained latent in the mind, even when thoſe occaſions preſented themſelves to which they are immediately applicable. In conſequence of this law of our nature, not only are all our various ideas made to paſs from time to time in review before us, and to offer themſelves to our choice as ſubjects of meditation; but when an occaſion occurs which calls for the aid of our paſt experience, the occaſion itſelf recalls to us all the information upon the ſubject which that experience has accumulated." Our author obſerves, "that the various theories which have attempted to account for memory by traces or impreſſions in the ſenſorium, are obviouſly too unphiloſophical to deſerve a particular refutation." He adds, after ſome other appropriate remarks on this ſubject, "that the immediate dependence of this faculty on the ſtate of the body, which is more remarkable than that of any other faculty whatever, (as appears from the effects produced on it by old age, diſeaſe, and intoxication,) is apt to ſtrike thoſe who have not been much converſant with theſe inquiries, as beſtowing ſome plauſibility on the theory which attempts to explain its phenomena on mechanical principles." Accordingly, it is recommended to medical writers to be at more pains than they have been at hitherto, in order to aſcertain the various effects which are produced on the memory by diſeaſe and old age; effects which are widely diverſified in different caſes. "In ſome it would ſeem that the memory is impaired, in conſequence of a diminution of the power of attention; in others, that the power of recollection is diſturbed, in conſequence of a derangement of that part of the conſtitution on which the aſſociation of ideas depends. The decay of memory, which is the common effect of age, ſeems to ariſe from the former of theſe cauſes."—"As far as the decay of memory, which old age brings along with it, is a neceſſary conſequence of a phyſical change in the conſtitution, or a neceſſary conſequence of a diminution of ſenſibility, it is the part of a wiſe man to ſubmit cheerfully to the lot of his nature. But it is not unreaſonable to think, that ſomething may be done by our own efforts, to obviate the inconveniences which commonly reſult from it. If individuals, who, in the early part of life, have weak memories, are ſometimes able to remedy this defect, by a greater attention to arrangement in their tranſactions, and to claſſification among their ideas, than is neceſſary to the bulk of mankind, might it not be poſſible, in the ſame way, to ward off, at leaſt to a certain degree, the encroachments which time makes on this faculty? The few old men, who continue in the active ſcenes of life to the laſt moment, it has been often remarked, complain, in general, much leſs of a want of recollection than their contemporaries. This is undoubtedly owing partly to the effect which the purſuits of buſineſs muſt neceſſarily have in keeping alive the power of attention. But it is probably owing alſo to new habits of arrangement, which the mind gradually and inſenſibly forms from the experience of its growing infirmities."

The learned profeſſor devotes a ſection of his excellent work to the illuſtration of the varieties of memory in different individuals. "As the great purpoſe," he ſays, "to which this faculty is ſubſervient, is to enable us to collect, and to retain, for the future regulation of our conduct, the reſults of our paſt experience; it is evident that the degree of perfection which it attains in the caſe of different perſons, muſt vary; firſt, with the facility of making the original acquiſition; ſecondly, with the permanence of the acquiſition; and, thirdly, with the quickneſs or readineſs with which the individual is able, on particular occaſions, to apply it to uſe. The qualities of a good memory are, therefore, in the firſt place, to be ſuſceptible; ſecondly, to be retentive; and, thirdly, to be ready." Theſe three qualities are rarely united in the ſame perſon.

Our author has advanced ſome very ingenious and judicious obſervations on the difference between a *caſual* and a *philoſophical* memory. The bulk of mankind aſſociate their ideas chiefly according to their moſt obvious relations, thoſe, for example, of reſemblance and analogy; and, above all, according to the caſual relations ariſing from contiguity in time and place; whereas, in the mind of a philoſopher, ideas are aſſociated according to thoſe relations which are brought to light in conſequence of particular efforts of attention, with the relations of cauſe and effect, or of premiſes and concluſion. The advantage is greatly in favour of the philoſopher; the arrangement he uſes ſtrengthens his memory, aſſiſts his invention, enables him to reaſon ſynthetically, and to correct his intellectual defects; but this kind of memory is not favourable to converſation. The man of caſual memory is open to every impreſſion, and readily accommodates his ideas to any circumſtance which may occur. But the philoſopher who thinks cloſely and reaſons ſyſtematically, is deficient in eaſe and quickneſs, and is in danger of becoming tedious by long diſcourſes. And as nothing appears weaker or more abſurd than a theory partially ſtated, it frequently happens that men of ingenuity, by attempting it, ſink in the vulgar apprehenſion, below the level of ordinary underſtandings. Profeſſor Stewart, after pointing out in various particulars the difference between philoſophical and caſual memory, obſerves, that they conſtitute the moſt remarkable of all the varieties which the minds of different individuals, conſidered in reſpect of this faculty, preſent to our notice. He afterwards enumerates, in detail, and with appropriate illuſtration, ſeveral other varieties of a leſs ſtriking nature. Stewart's Elements of the Philoſophy of the Human Mind, chap. vi. § 1, 2, 3.

For the difference between memory and imagination; ſee IMAGINATION.

Ariſtotle diſtinguiſhes between memory and reminiſcence. Memory is a kind of habit which is not always in exerciſe with regard to things we remember, but is ready to ſuggeſt them when there is occaſion. The moſt perfect degree of this habit is, when the thing preſents itſelf to our remembrance ſpontaneouſly, and without labour, as often as there is occaſion. A ſecond degree is, when the thing is forgot for a longer or ſhorter time, even when there is occaſion to remember it, yet at laſt ſome incident brings it to mind without any ſearch. A third degree is, when we caſt about and ſearch for what we would remember, and ſo at laſt find it out. It is this laſt which Ariſtotle calls reminiſcence, as diſtinguiſhed from memory Reminiſcence, therefore, includes a will to recollect ſomething paſt, and a ſearch after it. Ariſtotle ſays, that brutes have not reminiſcence, which Dr. Reid thinks to be probable, but, ſays he, they have memory. Thus, a dog knows his maſter after long abſence. A horſe will trace back a road he has once gone as accurately as a man. Reid, *ubi ſupra*. See the preceding part of this article.

Hiſtory furniſhes us with ſeveral ſurpriſing inſtances of the retentive powers of the faculty of memory. Seneca ſays of himſelf, that, by the mere effort of his natural memory, he was able to repeat two thouſand words upon once hearing them, each in its order; though they had no dependence or connection on each other. After which he mentions a friend of his, Portius Latro, who retained in his memory all the declamations he had ever ſpoken, and never found

found his memory fail him, even in a ſingle word. He alſo mentions Cyneas, ambaſſador to the Romans from king Pyrrhus, who, in one day, had ſo well learnt the names of his ſpectators, that the next he ſaluted the whole ſenate, and all the populace aſſembled, each by his name. Pliny ſays, that Cyrus knew every ſoldier in his army by name; and L. Scipio, all the people of Rome. Charmipas, or rather Carneades, when required, it is ſaid, would repeat any volume found in the libraries as readily as if he were reading. Dr. Wallis tells us, that without the aſſiſtance of pen and ink, or any thing equivalent, he was able in the dark, by mere force of memory, to perform arithmetical operations, as multiplication, diviſion, extraction of roots, &c. to forty places. Particularly, that, in February 1671-2, at the requeſt of a foreigner (by night in bed) he propoſed to himſelf a number of fifty-three places, and found its ſquare root to twenty-ſeven places; and without ever writing down the number, dictated it from his memory, at his next viſit, twenty days afterwards.

The perfection of memory conſiſts in two things; readily to admit the impreſſions or images of things; and to preſerve them from oblivion, that the underſtanding may have recourſe to them, and employ them for ſuch purpoſes, as reaſon ſhall direct. In order to aſſiſt and improve this faculty, every kind of intemperance and exceſs muſt be carefully avoided; and when we would commit any thing to memory, our firſt concern ſhould be to underſtand it thoroughly; we ſhould commit things to memory in a methodical and regular manner; writing down any thing is likewiſe a great advantage towards remembering it; a frequent review and careful repetition of the things that are learned will help to fix them in the memory, and likewiſe an abridgment of them in a narrow compaſs; converſation upon them with intelligent companions will alſo be found uſeful; care ſhould likewiſe be taken not to overburden the memory: ſuch ſeaſons ſhould be made choice of as are moſt proper for the exerciſe of this faculty, ſuch are the evening and morning; and the moſt effectual way of gaining a good memory, is its conſtant and moderate exerciſe. Ward's Or. vol. ii. ſect. 51. Rollin's Belles Lettres p. 208—216, ſixth ed. Watts's Improvement of the Mind, ubi ſupra. Stewart's Elem. of the Philoſophy of the Human Mind, ch. vi. ſect. 3, 4, 5.

Memory, *Local*, or *Artificial*, is an art, or invention, by means of which the memory is ſuppoſed to be aided, ſtrengthened, and enlarged.

This art ſeems to conſiſt in nothing elſe but a certain method of coupling or aſſociating the ideas of things to be remembered, with the ideas of other things, already diſpoſed orderly in the mind, or that are before the eyes. It is of an old ſtanding, having been practiſed by many of the ancient rhetoricians, under the denomination of "topical memory;" ſome of whom are ſaid to have made uſe of paintings, images, and emblems, on this occaſion; though others contented themſelves with the parts, members, ornaments, furniture, and other circumſtances of the place where they were to ſpeak. Muretus tells us that a young man of Corſica pretending to do wonders this way, Muretus put him to the trial; and upon dictating to him two or three thouſand words, ſome Greek, ſome Latin, ſome Barbarous; all without any relation to each other, and the greateſt part without any meaning at all; the artiſt immediately, and without any heſitation, or the leaſt ſtumbling or diſplacing, repeated them all, from firſt to laſt, in the ſame order wherein they had been dictated; and this done, beginning where he ended, he repeated them all backwards, from laſt to firſt. Adding, that this was but a ſlight eſſay of his memory; and that he would undertake to repeat thirty-ſix thouſand words in the ſame manner.

The truth is, this art ſeems better calculated for retaining things without any coherence or dependence on one another, as mere words or ſounds, &c. than for things where reaſon or judgment are any way required.

Raim. Lully took ſo much pains with it, that it now goes by his name, being called *Lully's art*.

Many have been the attempts, in all ages, to aſſiſt the memory. Some have had recourſe to medicine, ſuch as Horſtius, Marſilius Ficinus, Johnſton and others. That good health, a good digeſtion, and a mind free from care, are helps in this reſpect, is an old obſervation. That attention, application, frequent recapitulation, are neceſſary, is known to every one. But whether, beſides natural health and parts, and the exerciſe of our faculties, art may not give a farther aſſiſtance to memory, has been a queſtion. Simonides is ſaid to have been the firſt who found out the art of memory. His method was by a choice of *places* and *images*, as a repoſitory of ideas; ſuch, for inſtance, as a large houſe divided into ſeveral apartments, rooms, cloſets, &c. All theſe, and their order, were to be rendered extremely familiar to the imagination and memory. Then, whatever was to be remembered, was by ſome ſymbolical repreſentation or another, as an anchor for navigation, to be connected with ſome part of the houſe, or other artificial repoſitory, in a regular manner. Cicero and Quintilian give us ſome account of this method, and ſpeak of it with reſpect. As far as it was the object of this ſpecies of artificial memory to aſſiſt an orator in recollecting the plan and arrangement of his diſcourſe, the accounts which are given of it by the ancient rhetoricians are abundantly ſatisfactory. It appears, however, that its uſe was more extenſive; and that it was ſo contrived, as to facilitate the recollection of a premeditated compoſition. In what manner this was done, it is not eaſy to conjecture from the imperfect explanations of the art, which have been tranſmitted to modern times. The reader may conſult Cicero de Orat. lib. ii. cap. 87, 88. Rhetor. ad Herennium, lib. iii. cap. 16, &c. Quintil. Inſt. Orat. lib. xi. cap. 2.

Several moderns have attempted improvements of artificial memory. There was a collection of various treatiſes of this kind publiſhed at Leipzig; this, and Bruxius's Simonides Redivivus, are commended by Morhof. Paſchius gives us ſome account alſo of ſeveral authors who have treated of this art. It is certainly of uſe in hiſtory and chronology. The chief artifice, in this reſpect, is to form an artificial word, the letters of which ſhall ſignify numbers. Hence a date or era may more eaſily be recapitulated and remembered than without ſuch a contrivance. This invention is mentioned as a ſecret known to few, by Paſchius. It has been proſecuted in England, by Dr. Grey, in his well-known work, entitled "Memoria Technica," by means of which a great maſs of hiſtorical, chronological, and geographical knowledge is compriſed in a ſet of verſes, which the ſtudent is ſuppoſed to make familiar to himſelf as ſchool-boys do the rules of grammar.

The method is this: to remember any thing in hiſtory, chronology, geography, &c. a word is formed, the beginning of which being the firſt ſyllable or ſyllables of the thing to be remembered, does, by frequent repetition, of courſe draw after it the latter parts, which is ſo contrived as to give the anſwer. Thus, in hiſtory, the deluge happened in the year before Chriſt 2348. This may be ſignified by the word Dél *étok*; Del ſtanding for deluge, and *etok* for 2348.

How

How these words came to signify these things, or contribute to the remembering them, is now to be shewn.

The first thing to be done is to learn exactly the following series of vowels and consonants, which are to represent the numerical figures, so as to be able at pleasure to form a technical word, which shall stand for any number, or to resolve a word already formed into the number it stands for:

a	*e*	*i*	*o*	*u*	*au*	*oi*	*ei*	*ou*	*y*
1	2	3	4	5	6	7	8	9	0
b	*d*	*t*	*f*	*l*	*s*	*p*	*k*	*n*	*z*

Here *a* and *b* stand for 1, *e* and *d* for 2, *i* and *t* for 3, and so on. These letters are assigned arbitrarily to the respective figures, and may very easily be remembered. The first five vowels in order naturally represent 1, 2, 3, 4, 5. The diphthong *au*, being composed of *a*, 1, and *u*, 5, stands for 6; *oi* for 7, being composed of *o*, 4 and *i*, 3; *ou* for 9, being composed of *o*, 4 and *u*, 5; the diphthong *ei* will easily be remembered for 8 (eight), being the initials of the word. In like manner for the consonants, where the initials could conveniently be retained, they are made use of to signify the number, as *t* for 3, *f* for four, *s* for six, and *n* for 9. The rest were assigned without any particular reason, unless that possibly *p* may be more easily remembered for 7, or *septem*, *k* for 8, or *οκτω*, *d* for 2, or *duo*; *b* for 1, as being the first consonant, and *l* for 5, being the Roman letter for 50, than any others that could have been put in their places. It is farther to be observed, that *z* and *y* being made use of to represent the cypher, where many cyphers meet together, as 1000, 1000000, &c. instead of a repetition of *azyzyzy*, &c. let *g* stand for 100, *th* for a thousand, and *m* for a million. Thus *ag* will be 100, *ig* 300; *oug* 900, &c. *ath* 1000, *am* 1000000, *loum* 59000000, &c. Fractions may be set down in the following manner: let *r* signify the line separating the numerator and denominator, the first coming *before* the other *after* it; as *iro* $\frac{3}{4}$, *urp*, $\frac{5}{7}$, *pourag* $\frac{79}{100}$, &c. When the numerator is 1 or unit, it need not be expressed, but begin the fraction with *r*; as *re* $\frac{1}{2}$, *ri* $\frac{1}{3}$, *ro* $\frac{1}{4}$, &c. So in decimals, *rag* $\frac{1}{100}$, *rath* $\frac{1}{1000}$.

This is the principal part of the method, which consists in expressing numbers by artificial words. The application to history and chronology is also performed by artificial words. This part of the art consists in making such a change in the ending of the name of a place, person, planet, coin, &c. without altering the beginning of it, as shall readily suggest the thing sought, at the same time that the beginning of the word, being preserved, shall be a leading or prompting syllable to the ending of it so changed. Thus in order to remember the years in which Cyrus, Alexander, and Julius Cæsar, founded their respective monarchies, the following words may be formed; for Cyrus, Cyr*uts*; for Alexander, Alex*ita*; for Julius Cæsar, Juli*os*. *Uts* signifies, according to the powers assigned to the letters before mentioned, 536; *ita* is 331, and *os* is 46. Hence it will be easy to remember, that the empire of Cyrus was founded 536 years before Christ, that of Alexander 331, and that of Julius Cæsar, 46.

For the farther application of this method, we refer to the ingenious author's own account. We shall only add, that technical verses contribute much to the assistance of the memory, both as they generally contain a great deal in a little compass, and also because, being once learned, they are seldom or never forgot. The author before quoted has given us several specimens of such verses in history, chronology, geography, and astronomy, as also the Jewish, Grecian, and Roman coins, weights and measures, &c. He advises his reader to form the words and verses for his own use himself; as he perhaps will better remember them than those formed by the author

Having given an account very much in detail of the most approved artifices that have been contrived for assisting the memory, our limits will not allow our specifying any of those modern methods for this purpose that have engaged popular attention; probably without much claim to originality, and which, as long as they are not explicitly divulged, may be more lucrative to those who teach than improving to those who are at the pains and expence of acquiring them. Every attempt, however, to improve this important faculty merits encouragement. See MNEMONIC *Tables*.

Concerning the utility of the system above stated, the ingenuity of which has been acknowledged, opposite opinions have been entertained. The prevailing opinion is, as professor Stewart conceives, against it; although it has been mentioned in terms of high approbation by some writers of eminence. Dr. Priestley, whose judgment in matters of this nature commands respect, has said of it (Lectures on History, p. 157), that "it is a method so easily learned, and which may be of so much use in recollecting dates when other methods are not at hand, that he thinks all persons of a liberal education inexcusable, who will not take the small degree of pains that is necessary to make themselves masters of it; or who think any thing mean, or unworthy of their notice, which is so useful and convenient." The learned professor, of whose observations we have so often availed ourselves, very justly remarks, that "in judging of the utility of this, or of any other contrivance of the same kind, to a particular person, a great deal must depend on the species of memory which he has received from nature, or has acquired in the course of his early education. Some men have an extraordinary facility in acquiring and retaining the most barbarous and the most insignificant verses; which another person would find as difficult to remember, as the geographical and chronological details of which it is the object of this art to relieve the memory. Allowing, therefore, the general utility of the art, no one method, perhaps, is entitled to an exclusive preference; as one contrivance may be best suited to the faculties of one person, and a very different one to those of another."—"One important objection applies to all of them, that they accustom the mind to associate ideas by accidental and arbitrary connections; and, therefore, how much soever they may contribute, in the course of conversation, to an ostentatious display of acquired knowledge, they are, perhaps, of little real service to us, when we are seriously engaged in the pursuit of truth. I own too, (says the professor,) I am very doubtful with respect to the utility of a great part of that information which they are commonly employed to impress upon the memory, and on which the generality of learned men are disposed to value themselves. It certainly is of no use, but in so far as it is subservient to the gratification of their vanity; and the acquisition of it consumes a great deal of time and attention, which might have been employed in extending the boundaries of human knowledge. To those, however, who are of a different opinion, such contrivances as Grey's may be extremely useful; and to all men they may be of service, in fixing in the memory those insulated and uninteresting particulars, which it is either necessary for them to be acquainted with, from their situation; or which custom has rendered, in the common opinion, essential branches of a liberal education."

As to Simonides's method, Quintilian says he will not deny it to be of some use; for instance, in repeating a multitude of of words in the order they occur, and in things of this nature; but he thinks it of less use in getting by heart a continued oration, and in this respect rather an incumbrance. He himself advises, if the speech to be remembered be long, to get it by heart in parts, and those not very small. The partition ought chiefly to be made according to the different topics. He thinks it best to get things by heart tacitly, and if, the better to fix the attention, the words be pronounced, yet it should be in a low voice. Apt divisions help the memory greatly. But after all, the great art of memory is exercise; to get many things by heart, and daily, if possible. Nothing increases more by use, or suffers more by neglect, than the memory. At whatever age a man aims at the improvement of this faculty, he should patiently submit to the uneasy labour of repeating what he has read or written. Here, as in other cases, where habits are to be acquired, exercise should be increased by degrees. Quint. Inst. Orat. lib. xi. cap. 2. p. 989.

Lord Bacon enumerates several helps to memory, as order, artificial place, verse, whatever brings an intellectual thing to strike the senses, and those things which make an impression by means of a strong passion, as fear, surprize, &c. Those things also sink deepest, and dwell longest in the memory, which are impressed upon a clear mind unprejudiced either before or after the impression, as the things we learn in childhood, or think of just before going to sleep; as likewise the first time things are taken notice of.

A multitude of circumstances also, or, as it were, handles or holds to be taken, help the memory; as the making many breaks in writing, reading or repeating aloud; but as to this last, see Quintilian's opinion before mentioned. Those things which are expected, and raise the attention, stick better than such as pass slightly over the mind; whence if a man reads any writing twenty times over, he will not remember it so well, as if he read it but ten times with trying between whiles to repeat it, and consulting the copy where his memory failed. Bacon's Works abr. vol. ii. p. 475. See also vol. i. p. 135, 136. vol. iii. p. 176, and the article MNEMONIC *Tables*.

MEMORY, *Weakness* or *Loss of*, in *Medicine*, technically called *amnesia*, is a disease which appears to depend upon two opposite conditions of the brain; namely, upon a plethora or oppressed state of that organ, and upon an extreme debility of its vessels and languor of the circulation. Hence it arises from two different sets of causes, and is to be cured by two opposite modes of treatment. The first mentioned species of the disease is connected with the lethargic state preceding apoplectic attacks, or with the paralytic condition that often succeeds them: it arises also from local injury to the brain, occasioned by wounds and blows, which produce concussion or pressure upon the brain. The plan of treatment directed for these morbid states, and consisting chiefly of local evacuations, with low diet, will be necessary for the relief of these varieties of *amnesia*. But the second species, connected with a feeble circulation in the head, such as is said to arise from excessive indulgence of the venereal appetite, or to follow the continued use of spirituous liquors, where there is no plethora, requires the use of tonics and of opium; the exciting causes being also avoided. (See Sauvages Nosol. Method. Spec. 1. Amnesia à Venere. Spec. 7. A. à temulentia.) Where the disease results from old age, however, or from any organic changes, which may have taken place in the brain itself, a cure cannot of course be expected from any expedient.

MEMORY, *Time of*, in *Law*, has been long ago ascertained by the law to commence from the beginning of the reign of Richard I. (2 Inst. 238, 239.) This rule was adopted, when by the statute of Westm. 1. (3 Edw. I. c. 39.) the reign of Richard I. was made the time of limitation in a writ of right. But since by the statute 32 Hen. VIII. c. 2. this period (in a writ of right) hath been very rationally reduced to sixty years, it seems unaccountable that the date of legal prescription or memory should still continue to be reckoned from an era so very antiquated. See Litt. § 170. 34 Hen. VI. 37. 2 Roll. Abr. 269. pl. 16. See MODUS.

MEMORY *Rocks*, in *Geography*, a reef of rocks among the Bahama islands. N. lat. 27° 3'. W. long. 79° 30'.

MEMPHIS, in *Ancient Geography*, a large and populous city of Egypt, on the left side of the Nile. Concerning the epocha of its foundation and also of its destruction, as well as its precise situation, writers are not agreed. According to Diodorus Siculus it was seven leagues in circumference, and it contained magnificent temples and palaces. As to its position, Dr. Shaw says, that opposite to Cairo, on the banks of the Nile, which looks towards Libya, is the village of Gisa, where the ancient Memphis stood, the ruins of which are now covered and buried with earth. The authors of the Universal History adopt the opinion of Dr. Shaw, and represent Memphis as situated on the scite now occupied by Gisa. According to Herodotus, Memphis was situated on the narrowest spot in Egypt, on the western bank of the Nile; a lake formed by the waters of the river surrounding it to the north and the west. But Strabo is more circumstantial in his details; and he says, that at 40 stadia, or 1¼ league from Memphis, rises a stony hill, where a great number of pyramids are built. This situation, it is said, does not correspond with that of Gisa, which is three leagues from the nearest pyramids, and six from those of Saccara. (See GIZÉ.) Pliny (N. H. l. vi.) says, that the three great pyramids, which are seen by navigators from all parts, are situated on a barren and stony hill, between Memphis and the Delta, one league from the Nile, two from Memphis, and near the village of Busiris. Diodorus also places the pyramids 15 miles from Memphis. From these authorities we may infer, that as the pyramids are between Memphis and the Delta, and it is certain that Gisa or Gizé is between the pyramids and the Delta, Memphis could not have been situated on the spot where Gisa stands; or, in other words, Memphis, by Pliny's description, is two leagues to the southward of the pyramids, and Gisa being three leagues from them to the northward, it could not have been built on the ground occupied by Memphis. Moreover, the village of Busiris still exists under the name of Busir, at a small distance from the pyramids; they are still a league from the river, and the small town of "Menph," formerly Memphis, is about two leagues to the southward of these monuments.

The foundation of this city is ascribed by Herodotus to Menes; and by Diodorus to Uchoreus, the eighth descendant of Osymandias. Some have proposed to reconcile these two accounts by attributing the commencement of the city to Menes, and its completion and aggrandizement to Uchoreus, who made it a royal city. The occasion of its having been erected is thus stated by Savary. After a king of Egypt had turned the course of the Nile, which lost itself in the sands of Libya, and the Delta was formed out of the mud deposited by its waters, canals were cut to drain the Lower Egypt. The monarchs who till that time had fixed their residence at Thebes, were desirous of coming nearer the mouth of the river, to enjoy a more temperate air, and to be more ready to defend the entrance of their empire. Accordingly they founded the city of Memphis, and strove to make it a rival worthy of the ancient capital. They adorned it,

 as

as Strabo (lib. xvii.) informs us, with ſeveral temples, amongſt which that of Vulcan attracted the attention of travellers, by the grandeur of the edifice and the richneſs of its ornaments. Another temple, no leſs an object of wonder, was dedicated to Serapis, the principal approach to which was adorned by prodigious ſphinxes. Here was alſo a temple of Venus, which ſome have ſuppoſed to be the moon. In order to prevent the diſaſter which was likely to be occaſioned by drifts of ſand, the inundations of the river, and the attacks of an enemy, a long and lofty dyke was conſtructed towards the ſouth; and on the weſt, it was defended by the king's palaces and a fortreſs erected on the mountain. On the eaſt it was bounded by the Nile. Towards the north were lakes terminated by the plain of Mummies, and by the cauſeway which leads from Buſiris to the great pyramids. Thus ſituated, Memphis commanded the valley of Egypt, and communicated by canals with lake Mœris, and lake Mareotis. The citizen who inhabited it might travel from his own houſe all over Egypt in a boat; ſo that it became the centre of wealth, of commerce, and of the arts. The new capital, thus circumſtanced, ſunk Thebes and her 100 gates into oblivion; and the glory of Memphis laſted for many ages. It maintained its ſplendour till Cambyſes laid waſte Egypt at the head of a formidable army. This ferocious conqueror deſtroyed, as far as he was able, her temples and her famous buildings; and, above all, he ſtrove to extinguiſh the torch of the ſciences, which the Egyptians, ſurrounded by waves and deſerts, had lighted in their fertile valley. Memphis, however, retained ſo many traces of her magnificence as to be ſtill the firſt city in the world. For upwards of 200 years ſhe laboured to throw off the Perſian yoke. Alexander, to whom ſhe ſurrendered, amply revenged the outrages ſhe had ſuſtained. This conqueror, abandoning himſelf to a guilty delirium, removed, as Quintus Curtius informs us, within the walls of Perſepolis, the horrors Cambyſes had committed at Thebes and Memphis. In proceſs of time a city was founded which bore his name; and it was embelliſhed by the Ptolemies, his ſucceſſors. Alexandria became another Rome: the arts and ſciences acquired reputation in this place: commerce alſo attracted hither wealth from various regions. Hence it happened, that Memphis was gradually depopulated by the migration of her inhabitants to the new and more favoured city. Under Auguſtus, however, it was ſtill a great city, populous and full of ſtrangers; though it then held the rank of only the ſecond city of Egypt. Six hundred years after, it became the firſt conqueſt of the Arabs, who laid ſiege to its walls. The ſiege was long and bloody; but it was carried at length by ſtorm, as Abulfeda informs us. Menf (Memphis), ſays this writer, is the ancient Maſr of Egypt. It is ſituated on the weſtern bank of the Nile. Amrou, ſon of El Aas, having taken it by ſtorm, raſed it to the ground, and went to build the town of Foſtat by order of Omar, ſon of Kettah, on the oppoſite ſide. At Menf are remarkable ruins, the remains of its ancient ſplendour, &c. Menf, he adds, is diſtant a ſhort day's journey from Grand Cairo. The village of Menf, the ſad remains of an immenſe city, is ſix leagues from Grand Cairo, on the weſtern bank of the Nile. The lakes mentioned by Herodotus and Strabo have not entirely diſappeared; one of them is near Saccara, with a wood of Acacia ſituated weſtward of Menf; the other is preciſely north of it. (Savary's Letters on Egypt, vol. i.) Memphis gave name to a nome or canton of Egypt, ſituated on the weſt of the Nile, and called "Memphitis Nomos."

MEMPHITES, or *Lapis Memphiticus*, a ſort of ſtone mentioned by Dioſcorides, Pliny, and other natural hiſtorians, ſuppoſed to be found in Egypt, not far from the city of Cairo, the ancient Memphis, whence its name.

The property it is famed for is, that being pulverized and ſmeared on any part of the body to be cut off, it deadens it ſo, as that the patient ſhall receive no pain, they ſay, from the operation.

MEMPHREMAGOG, in *Geography*, a lake which lies chiefly in the province of Canada, 40 miles in length from north to ſouth, and two or three wide from eaſt to weſt. The north line of Vermont ſtate paſſes over the ſouth part of the lake, in N. lat. 45°. This lake, which communicates by the river St. Francis with the river St. Laurence, is the reſervoir of three conſiderable ſtreams, *viz.* Black, Bolton, and Clyde rivers, which riſe in Vermont. The ſoil on its banks is rich, and the country round it is level.

MEMRAMCOOK RIVER, a river of America, which has been recommended as the moſt proper boundary between the province of North Brunſwick and Nova Scotia. It lies a little to the eaſtward of Petitcodick, and purſues a north-eaſterly direction.

MEMRUMUS, in *Mythology*, a Phœnician deity, ſprung from the race of giants, and the brother of Hypſaranius. The latter dwelt at Tyre, and invented the art of building cottages of reeds and ruſhes, and the papyrus; and his brother, with whom he quarrelled, taught men to clothe themſelves with the ſkins of beaſts. When an impetuous fire kindled a foreſt near Tyre, he took a tree, cut off its branches, and having launched it in the ſea, made uſe of it for a ſhip. He alſo paid religious homage to two ſtones, which he had conſecrated to the wind and fire, and poured out libations to them of the blood of certain animals. This, ſays Banier, is the ſecond example of a worſhip paid to created beings; the ſun having been the firſt object of idolatry. After the death of theſe two brothers, their children, ſays Sanchoniathon, conſecrated to them mis-ſhapen pieces of wood and ſtone, which they adored, and inſtituted anniverſary feſtivals to their honour. This is the firſt time we find religious worſhip performed to dead men.

MEN—*Midſhipmen, Moot, Port, Queſt, Sides, Twelve, Veſtry* MEN. See the adjectives.

MEN, an abbreviation of the Italian adverb, *meno*, frequently uſed, in muſic, to announce a diminution; as *men forte*, leſs loud, &c.

MEN *of May*, in *Geography*, rocks near the north coaſt of Scotland; 5 miles E. from Dunnat Head. N. lat. 58° 3′. W. long. 3° 3′.

MENA, JUAN DE, in *Biography*, a Caſtilian poet of great celebrity, was born at Cordova about the year 1411. It was not till the age of twenty-three that he diſcovered any propenſity towards literature; but then he made up for the time which he conſidered as having been loſt, and betook himſelf moſt paſſionately to his ſtudies, which he purſued firſt at Cordova, then at Salamanca, and afterwards at Rome. By his poetical talents he ſoon attracted a conſiderable degree of notice, and was patronized by ſeveral conſiderable perſons, and by Juan II. This king, though far from reſpectable as to character or talents, was a lover of learning, and an encourager of it, and appointed Juan de Mena his chronicler, communicated to him materials for the hiſtory of his reign, and took delight in beholding the progreſs of his works. The hiſtory was never finiſhed by de Mena; and he is chiefly known as a poet. The longeſt and moſt elaborate of his poems is entitled "El Labyrintho," commonly known by the title of "Las Trezientas," becauſe it conſiſts of three hundred ſtanzas. Mr. Southey, in the General Biography, has given a pretty full account of the plan and contents of this poem. It is ſaid that the king ordered

dered him to add fixty-five ftanzas to his poem, for this *wife* reafon, that there might be juft as many as there are days in the year. Of thefe, twenty-four are printed at the end of the poem. They contain fome execrable flattery of Juan, and an orthodox addrefs to the deity; the reft is declamation againft the factious nobles. Juan de Mena was probably not the author of thefe. He has been greatly praifed in this country, and has been faid to unite the merits of Dante and Petrarca; but, according to Mr. Southey, the merits of Juan are exclufively what he may poffefs for his language: there is no glimpfe of imagination, and fcarcely a trace of feeling. De Mena was author of two other poems, entitled "La Coronacion," and "Tractado de Vicios y Virtudes." This laft he left unfinifhed. There are many editions of thefe poems; the moft complete are thofe of Seville in 1528, and of Antwerp in 1552. In the royal library at Madrid there is an unfinifhed abridgment of the Iliad, made by this author at the king's command. He died in 1456 at Tordelaguna, and was buried in the parochial church of that town. Gen. Biog.

Mena, in *Geography*, a town of Mexico, in the province of Nicaragua, on a river which runs into the lake of Nicaragua; 30 miles N.W. of St. Carlos.

Mena, in *Hindoo Mythology*, is the fpoufe of Himalaya, and mother of Parvati, in one of her terreftrial incarnations. The legend connected with this poetical fiction is very wild and fanciful. Himalaya, or the manfion of fnow, is the Hindoo claffical name of that vaft chain of mountains that bounds India to the north, and embraces it with its eaftern and weftern arms, both extending to the ocean: one named, in Sanfcrit, Chandra-Sekra, or moon-crowned; and the other, which ftretches weftward to the mouths of the Indus, was called by the ancients Montes Parveti. The mountain Himalaya, being perfonified, is reprefented as a powerful monarch, bearing the moon as his crown, and being the fource of all the good derivable from the many rivers that iffue from him. Thefe mountains were the refort of the god Siva; and his celeftial confort having no children by him, became regenerated in the daughter of Himalaya and Mena, and was named Parveti, or mountain-born. In this incarnation, fhe, according to fome legends, bore him two fons: Ganefa, the wifeft of deities, the god of prudence and policy, always invoked at the beginning of every literary work; and Kartikya, commander of the celeftial armies. (See Kartikya, Siva, and Parvati.) The name Himalaya is ufually altered by European writers to Himmaleh; the range of mountains is otherwife called Hindookho. See thefe articles. See alfo Mera.

MENACES, in *Law*. See Threats.

MENACHA, in *Geography*, a town of Arabia, in Yemen; 36 miles W.S.W. of Sanaa.

MENACHANITE, or Menakanite. See Titanium.

MENADON Bay, or *Panadon*, in *Geography*, a bay which lies two leagues from Port Balena, or Port Nove, on the coaft of Cape Breton ifland, at the fouth part of the gulf of St. Laurence, having the ifland of Scatair, formerly called Little Cape Breton, oppofite to it.

MENAGE, Gilles, in *Biography*, a diftinguifhed man of letters, was born at Angers in the year 1613, of which city his father was a king's advocate. Having completed his ftudies, he was admitted to the bar at Angers in 1632. He remained here but a fhort time, but went to Paris in the fame year, where he purfued the legal profeffion, till he became difgufted with the chicanery connected with it, and adopted the ecclefiaftical character, and thence gave himfelf up entirely to literary purfuits. He was foon diftinguifhed among his contemporaries as a man of wit and erudition; but by the ufual freedom of his remarks on different characters with whom he affociated, he was perpetually involved in quarrels. For fome years he was an inmate in the houfe of cardinal de Retz; and when he quitted it, he took apartments in the cloifter of Notre Dame, where he held weekly affemblies of the learned, to which he gave the title "Mercuriales." Menage was in eafy circumftances. He had fold a fmall paternal eftate for a life-annuity, enjoyed a confiderable rent-charge upon two abbies, and obtained a royal penfion, which, however, was paid but a fhort time. By thefe means he was enabled to cultivate literature in the way moft agreeable to him, and to print fome of his works at his own expence, which the bookfellers would probably not have chofen to undertake. By a witty fatire, entitled "Requête des Dictionnaires," he had precluded himfelf from an admiffion into the French academy, though it was afterwards a great object of his ambition. In the former part of his life he was diftinguifhed by a prodigious memory; but in advanced age he experienced almoft a total failure of that important faculty. Fortunately this defect was not permanent: he recovered it again, and recorded the grateful feelings of his heart in a Latin hymn to "Mnemofyne." He died at Paris in 1692, at the age of feventy-nine. His principal works are, 1. "Dictionnaire Etymologique, ou Origines de la Langue Françoife," firft printed in 1650, and reprinted in 1750, with corrections and additions by M. Jault, in two volumes, folio: it is regarded as a work of much real value, though in the firft editions there are numerous errors and abfurd etymologies. 2. "Origines de la Langue Italienne:" in this he was affifted by feveral members of the academy of Della Crufca, of which he was an affociate. 3. "Mifcellanea," in quarto, being a collection of pieces in profe and verfe, and in different languages. He alfo publifhed an edition of Diogenes Laertius, with notes and illuftrations; "Juris Civilis Amœnitates;" "Notes on the Poems of Malherbe;" "Hiftoire de Sable;" "Hiftoria Mulierum Philofophorum," and feveral other pieces. Menage was an entertaining companion, by the variety of his knowledge, and the happy manner which he had of communicating it; but he was apt to be overbearing and opiniative. After his death, a "Menagiana" was compiled from notes of his converfation, anecdotes, remarks, &c. which has been feveral times reprinted. The laft edition was publifhed in 1715 by M. de la Monnoye, in four volumes, 12mo. Moreri.

In his admirable work, entitled "Dictionnaire Etymologique de la Langue Françoife," and in his "Origine della Lingua Italiana," curious inquirers after the mufical language of the middle ages will find more information than in any other Lexicons or philofophical works with which we are acquainted, except in the Gloffarium of Ducange.

Menage, *Fr.*, denotes a collection of animals; whence we have derived the word *menagery*.

Menage, in *Geography*, an ifland in the river Senegal.

MENAGIO, a town of Italy, in the department of the Lario; 15 miles N.N.E. of Como.

MENAI, a channel between the ifland of Anglefey and the county of Caernarvon.

MENAIS, in *Botany*, perhaps from μενω, *to ftand undaunted againft the attacks of an enemy*, becaufe this fhrub is, as its fpecific name *topiaria* expreffes, able to bear clipping, and platting into bowers. No explanation of the name having been given, we offer the beft that occurs to us. Linn. Gen. 95. Schreb. 130. Willd. Sp. Pl. v. 1. 997. Loefl. It. 306. Juff. 128. Lamarck Dict. v. 4. 90.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Afperifoliæ*, Linn. *Borragineæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of three lax, concave, fmall, ſmall, pointed, ſtriated, permanent leaves. *Cor.* of one petal, ſalver-ſhaped; tube cylindrical, longer than the calyx; limb ſpreading, in five deep rounded ſegments. *Stam.* Filaments five, very ſhort; anthers awl-ſhaped, in the mouth of the corolla. *Piſt.* Germen ſuperior, roundiſh, depreſſed; ſtyle thread-ſhaped, erect, the length of the tube; ſtigmas two, oblong, acute. *Peric.* Berry globoſe, of four cells. *Seeds* ſolitary, nearly ovate, acute at one end.

Eſſ. Ch. Corolla ſalver-ſhaped. Calyx of three leaves. Berry of four cells. Seeds ſolitary.

1. M. *topiaria.* Bower Menais. Linn. Sp. Pl. 251.—Native of South America. A *ſhrub*, with round, ſomewhat hairy *ſtems*. *Leaves* alternate, ovate, undivided, rough. We have ſeen no figure nor ſpecimen of this plant. Linnæus mentions Aymen as the author of the genus. Juſſieu ſuſpects it not to be different from *Ehretia*, to which we have chiefly to object the three-leaved calyx. See Ehretia.

MENAKA, the name of a ſemi-divine female, in the Puranic romances of the Hindoos, frequently alluded to in their writings and converſation, proverbially, as highly beautiful and faſcinating. When the evil counſellor Indra, (ſee Indra,) jealous of the growing ſanctity of the aſcetic Viſwamitra (which ſee), reſolved to counteract his meritorious penance, he thought female blandiſhment the readieſt mode of debauching the ſaint; and ſelected Menaka, as a promiſing inſtrument through whom to effect his unholy purpoſe. The moral legend is thus alluded to in the 50th ſection of the firſt book of the Ramayana. (See that article.) "When the ſanctified aſcetic Viſwamitra, who had for thouſands of years been engaged in the moſt rigid mortifications, beheld Menaka the Apſara, ſent by Indra to debauch him, bathing, of ſurpriſing form, unparalleled in beauty, in appearance reſembling Sri (ſee Sri), her clothes wetted by the ſtream, exhibiting her faſcinating ſymmetry of frame; he, ſubdued by the arrows of Kandarpa (ſee Kandarpa), approached her; and five times five years, ſpent in dalliance with this ſeducing female, paſſed away like a moment. What!—exclaimed at length the reflecting ſage,—my wiſdom, my auſterities, my firm reſolution, all deſtroyed at once by a woman! Seduced by the crime in which Indra delights, am I ſtripped of the advantages ariſing from all my auſterities!" In this manner we occaſionally find ſound morality inculcated by the wild fables of the Hindoos. If we object to the warmth of language ſometimes obſervable in ſuch writings, we ſhould recollect that in fairneſs we ought not to eſtimate them by any ſtandard of European criticiſm; but ſhould advert to the uſages of the people, the times, and the countries, for whom and wherein they were promulgated.

MENALD Deer, a ſpecies of the common fallow-deer, beautifully variegated.

MENAMAN, in *Geography*, a town of Aſiatic Turkey, in Natolia, ſituated on the north coaſt of the gulf of Smyrna; 6 miles N.W. of Smyrna.

MENANDER, in *Biography*, the moſt celebrated of the Greek comic poets, was born at Athens in the year 342 B.C. He is conſidered as the perſon who introduced the new comedy, which refined upon the groſſneſs and licence of the old, and baniſhed living characters from the ſtage. He is repreſented as poſſeſſing every part of a perfect dramatic writer, *viz.* elegance of language, force and delicacy of ſentiment, and the true and humorous delineation of character. He was ſo much the poet of nature, that the grammarian Ariſtophanes once exclaimed, "O Menander and Nature, which of you copied from the workmanſhip of the other!" Quintilian praiſes him for the ſtrength and conſiſtency diſplayed in the characters of his dramas. Ovid predicts that the fame of Menander would be immortal. His fame extended as far as the Greek language; and we are informed by the elder Pliny, that the kings of Egypt and Macedonia gave him preſſing invitations to their courts, and even offered fleets for his ſafe conveyance. He preferred, however, a life of freedom in his native city; yet he could not be accounted a moral philoſopher. By Plutarch he is called "the chief prieſt of Love;" and Suidas gives him the character of one "mad after women." Phædrus paints him as paying his compliments to Demetrius Phalereus at Athens, perfumed all over, with a flowing garment, and advancing with an affected and languid ſtep. He compoſed 108 comedies, eight of which obtained the theatrical prize. It is extraordinary that, of an author ſo much eſteemed as Menander was, nothing has come down to our time except ſome fragments, chiefly of the ſentimental kind, and generally of a gloomy and querulous tenour, which perhaps were characteriſtic only of the perſons into whoſe mouth they were put: and what remains of him does not mark ſo ſtrongly his own peculiar genius, as the taſte of thoſe ſelectors who have choſen his words to illuſtrate their own ideas. Thus, to the melancholy ſelector we owe the ſurvival of the ſad and peeviſh complaints on the many ſorrows to which fleſh is the natural heir. On the other hand, the ſtrikingly moral paſſages with which his works abounded alone caught the attention of the fathers of the primitive church, who found in the Greek comedian a ſtrain of piety ſo nearly approaching to their own faith and feelings, that all ideas of a preponderance of ſatire over moral precept muſt yield to evidence ſo irreſiſtible as the approbation of Clemens Alexandrinus and Euſebius. It is from theſe two ſources alone, the writings of the melancholy and pious man, that we are furniſhed with our ſpecimens of Menander. Happy had it been for us and the world, had the gay and the witty finiſhed the portrait of the bard, by tranſmitting to after-ages examples that would have enabled us to meaſure him by the ſtandards of humour, ſprightlineſs, and fancy. The ſuperiority of the Grecian dramatiſt was felt and acknowledged by Roman imitators; and Cicero frequently reprobates the prevailing partiality of his countrymen for ſuch foreign authors. Menander was drowned in the harbour of Piræus, in the year B.C. 293, at a period of his life when he had done enough to obtain immortality, and while the powers of his mind were unimpaired by age, and his genius ſufficiently ardent to do ſtill more. He is ſaid to have thrown himſelf into the ſea in a fit of jealouſy, occaſioned by his unfortunate competition with Philemon. He was vanquiſhed, as Aulus Gellius aſſerts, by the ſuperior intereſt rather than talents of his ſucceſsful rival; and the ſame writer relates, that, meeting him ſhortly after the conteſt had been decided, he aſked him, "If he did not bluſh at gaining the prize againſt him?" The fragments of Menander have been ſeveral times reprinted. The moſt complete edition is that of Le Clerc in 1709. To this, on account of many miſtakes in proſody, Bentley, in 1713, gave his "Emendationes in Menandri et Philemonis Reliquias." Monthly Mag.

MENANDRIANS, in *Eccleſiaſtical Hiſtory*, the moſt ancient branch of Gnoſtics; thus called from Menander their chief, ſaid by ſome, without ſufficient foundation, to have been a diſciple of Simon Magus, and himſelf a reputed magician.

He taught, that no perſon could be ſaved, unleſs he were baptiſed in his name: and he conferred a particular ſort of baptiſm, which would render thoſe who received it immortal in the next world; exhibiting himſelf to the world, with the phrenſy of a lunatic more than the founder of a ſect, as a promiſed ſaviour. For it appears by the teſtimonies of Irenæus, Juſtin, and Tertullian, that he pretended to be one of the

the Æons fent from the pleroma, or ecclefiaftical regions, to fuccour the fouls that lay groaning under bodily oppreffion and fervitude; and to maintain them againft the violence and ftratagems of the dæmons that hold the reins of empire in this fublunary world. As this doctrine was built upon the fame foundation with that of Simon Magus, the ancient writers looked upon him as the inftructor of Menander. See SIMONIANS.

MENAN-FAN, in *Geography*, a town of Siam; 6 miles N. of Porfelon

MENANGEABOW, a kingdom of Sumatra, being the principal fovereignty of the ifland, which formerly comprehended the whole, and ftill receives a fhadow of homage from the moft powerful of the other kingdoms, that have fprung up from its ruins. This kingdom is the principal feat of empire of the Malays, and of the whole ifland. It lies near the centre, extending partly to the northward, but chiefly to the fouthward of the equinoctial, about 60 or 100 miles. The country is, generally fpeaking, a large plain, bounded by hills, clear of woods, and, comparatively, well cultivated. It has an eafy communication with both fides of the ifland, lying nearer to the weftern coaft, but having the advantage, to the eaft, of the large rivers Racan, Indergeree, Siak, Jambee, and even Palembang, with which it is faid to have connection by means of a large lake, that gives fource to the two laft, as well as to the river of Cattown on the oppofite fide. Colonies of Malays from Menangeabow are fettled on feveral branches of Jambee river, or rather thofe fmall rivers which run into it. Here they collect large quantities of gold. The name of Menangeabow is faid to be derived from the words "menang," to win, and "carbow," a buffalo; from a ftory, which bears a very fabulous air, of a famous engagement on that fpot between the buffalos and tigers, in which the former are reported to have gained a complete victory. The actual power and refources of the fultan are, at this day, fcarcely fuperior to thofe of a common raja; yet he ftill afferts all his ancient rights and prerogatives, which are not difputed, as long as he refrains from attempting to carry them into force. His character is held in a facred light, and the obfcurity and air of myftery which furround his court, together with the influence of the Mahometan priefts, who regard him as the head of their religion, keep up this veneration. This empire is allowed to be very ancient; though when the Europeans firft made difcoveries in thefe parts, it was in its decline. Like the other people of Sumatra, thofe of Menangeabow are entirely without records or annals. They are expert at writing in the Arabic character; but their literature amounts to nothing more than tranfcripts of the Koran, and "cabar," or hiftoric tales, refembling our old romances, but having lefs ingenuity. They are famous for compofing fongs, called "pantoon," which fpread throughout the ifland. The arts, in general, are carried among them to a greater degree of perfection than by the other natives of Sumatra. The Malays are the fole fabricators of the gold and filver *filagree;* which fee. Menangeabow has alfo been celebrated for its confiderable traffic in gold, lying in the midft of the mines, where it is chiefly produced. Much cloth is wrought in, and exported from it. Here alfo have been manufactured, from the earlieft times, arms for their own ufe, and for the fupply of the northern inhabitants of the ifland, who are the moft warlike. Their guns are thofe pieces called matchlocks, nor is the improvement of fprings and flints yet adopted by them; their barrels are well tempered, and of the jufteft bore. Powder is made by them in great quantity, but it is defective in ftrength. Befides guns, they have other arms, which are, for the moft part, weapons of a make between that of a fcimitar and a knife. Their crufes are a fpecies of dagger of a particular conftruction, and are worn by all defcriptions of people. They have other implements of warfare, called "Ranjows," which are fharp-pointed ftakes of bamboo, of different lengths, ftuck into the ground, in order to penetrate the naked feet or body of an enemy. They are made ufe of in cafes of flight, to annoy and retard the purfuers, and planted in the path-ways, or among the long grafs, by the vanquifhed party as they run. They are alfo difpofed in the approaches to fortified doofoons. Their wars are generally carried on rather in the way of ambufcade, and furprife of ftraggling parties, than open combat. The foldiers have no pay, but the plunder is thrown into a common fund, and divided.

The people of Menangeabow are all Mahometans, and in that refpect diftinguifhed from the other inland inhabitants of the ifland. This country is looked upon as the fupreme feat of that religion; and next to a voyage to Mecca, which fome Sumatrans have undertaken, to have been at Menangeabow ftamps a man learned and of fuperior fanctity. With the change of their religion, the people of this country altered their language, laws, cuftoms, and manners. This was effected by the fettlement of the Malays among them.

By late accounts it appears, that the kingdom of Menangeabow, even in its limited ftate, is rent into various fovereignties. Marfden's Sumatra.

MENAPII, in *Ancient Geography*, a people who, in the time of Cæfar, inhabited the banks of the Lower Rhine. They were bounded on the N. and E. by the Mofa, and on the W. by the Scaldis. Their country correfponded to Brabant.

MENARD, LEON, in *Biography*, an hiftorical writer, was born at Tarafcon in 1706. It is imagined he was educated for the legal profeffion, though he certainly did not purfue it to any great extent, but devoted moft of his time and talents to the ftudy of hiftory and antiquities. He obtained a place in the Academy of Infcriptions and Belles Lettres, and from that time paffed his life chiefly at Paris, where he died in indigent circumftances in 1767. His principal works are, "A Hiftory of the Bifhops of Nifmes," in two vols. 12mo.: "L'Hiftoire civile ecclefiaftique et litteraire de la Ville de Nifmes," which confifted of feven volumes 4to., and was the product of many laborious years. In depth of refearch, and abundance of curious matter, this is faid to be furpaffed by few topographical works. As a relaxation from more ferious labours, he compofed a romance, entitled "Les Amours de Califthene et d'Ariftoclie:" the fcene is laid in Ancient Greece, and it confifts in the delineation of Grecian manners, which fubject is exprefsly treated on in another work of our author, entitled "Mœurs et Ufages des Grecs," which was very much read, and proved honourable to his induftry and learning. He next carried his refearches into French hiftory, and publifhed, as the refult of his labours, a collection of "Pieces fugitives pour fervir a l'Hiftoire de la France," in three vols 4to. Another, and probably his laft publication, was entitled "A Refutation of the Arguments of Voltaire againft the Authenticity of the Political Teftament of Cardinal Richelieu." Gen. Biog.

MENARUOLO, in *Geography*, a town of Italy; 17 miles N.W. of Verona.

MENAS, ST., an ifland in the Grecian Archipelago, about fix miles in circumference. N. lat. 37° 33'. E. long. 26° 30'.

MENASSEH, BEN ISRAEL, in *Biography*, a celebrated rabbi, who flourifhed in the feventeenth century, was a native

tive of Spain, and born very early in that century. His father, after having been cruelly tortured by the Spanish Inquisition, and stripped of his property, escaped into Holland with his wife and sons, of whom Ben Israel, the subject of this article, was one. Here he was placed under a learned preceptor, Isaac Usieli, and pursued his studies with such diligence and success, that at the age of eighteen he was so deeply skilled in Hebrew and theology, that he was judged fully qualified to succeed his tutor as preacher and expounder of the Talmud in the synagogue of Amsterdam, a post which he occupied with high reputation for many years. He was not quite twenty-eight years of age, when he published in the Spanish language the first part of his work entitled "Conciliador:" of which was published a Latin version, in the following year, by Dionysius Vossius, entitled "Conciliator, sive de Convenientia Locorum S. Scripturæ, quæ pugnare inter se videntur, Opus ex Vetustis et Recentioribus omnibus Rabbinis magna Industria ac Fide congestum." This work shews that its author had a profound and intimate acquaintance with the Old Testament writings, and it procured for him the esteem and admiration of all the learned, as well Christians as Jews. It was recommended to the notice of biblical scholars by the learned Grotius.

Notwithstanding the learning and diligence of our rabbi, he found that the expences of a large and growing family could not be defrayed by the salary attached to his appointment, and engaged in the mercantile line of business; and he also set up a printing-press in his own house, at which he printed three editions of the Hebrew bible, and a number of other books. Under the protectorate of Cromwell, he came over to England, in order to solicit leave for the settlement of the Jews in this country. Here he met with a favourable reception from the protector and his parliament, and succeeded in obtaining greater and more important privileges for his nation than they had ever enjoyed before in this country, and in 1656 published an "Apology for the Jews," in the English language. This piece was afterwards published in the second volume of the collection of scarce and curious tracts entitled "The Phœnix," &c. Menasseh died at Amsterdam about the year 1659, and left a son, who inherited his printing-press, busily employed in printing some of his father's works. The rabbi was respected and esteemed as well for his moral virtues as for his great learning, and had been long in habits of correspondence and intercourse with some of the most learned men of his time, among whom were the Vossii, Episcopius, and Grotius. The following are his principal works independently of that already noticed: 1. An Edition of the Hebrew Bible, two vols. 4to.: 2. The Talmud corrected, with Notes: 3. De Resurrectione Mortuorum: and 4. Spes Israelis, dedicated to the parliament of England in the year 1650; it was originally published in Spanish, and afterwards translated into the Hebrew, German, and English, one object of which is to prove that the ten tribes are settled in America. He was author likewise of numerous other pieces. Moreri. Universal History.

MENAT, in *Geography*, a town of France, in the department of Puy-de-Dôme, and chief place of a canton, in the district of Riom; 24 miles N.N.W. of Riom. The place contains 1748, and the canton 10,014 inhabitants, on a territory of 180 kiliometres, in 11 communes.

MENCKE, Lewis Otho, in *Biography*, was born in 1644, at Oldenburg, in Westphalia, of which city his father was a senator, and also in trade. After studying at and visiting several of the universities in Germany and Holland, he was appointed professor of moral philosophy at Leipsic in 1668, He was, in the course of an active and well spent life, five times rector of the university, and occupied his post as professor till his death, in 1707. He was editor of several learned works, and was the planner of the periodical work called the Leipzig Journal, but better known by the name "Acta Eruditorum," of which, with the assistance of other learned men, he published thirty volumes. Moreri.

Mencke, John Burchard, son of the preceding, was born at Leipsic in 1674, and in 1699 we find him appointed to the professorship of history, an office in which he acquired a high reputation by his lectures. He was also historiographer and aulic counsellor to Frederic Augustus of Saxony, king of Poland; a member of the Academy of Berlin, and of the Royal Society of London. He died at Leipsic in 1732, leaving behind him several very learned and useful publications on historical and philosophical subjects. One of the most remarkable of these consisted of two Latin declamations, "De Charlataneria Eruditorum," which were translated into various languages. He had a large share in, and was the original projector of a German "Dictionary of Learned Men," but his chief undertaking was a collection of the German historians, under the title of "Scriptores rerum Germanicarum, speciatim Saxonicarum," in three volumes folio. He published an enlarged edition of Lenglet's "Methode pour etudier l'Histoire avec un Catalogue des principaux Historiens," and after the death of his father, he continued the Leipsic journal to thirty-three volumes more. Moreri.

MEND, in *Geography*, a town of Persia, in the province of Mekran, at the union of the Mekshid and the Nehenk, which hence take the name of Mend, and run into the Indian sea. The town is distant 40 miles S.W. from Kidge. N. lat. 25° 50′. E. long. 63° 30′.

MENDÆANS, in *Ecclesiastical History*. See Hemerobaptists.

MENDAMA, in *Geography*, a town of the island of Ceylon; 18 miles N. of Candi.

MENDAVIA, a town of Spain, in Navarre; 8 miles E.S.E. of Viana.

MENDE, a town of France, and principal place of a district, in the department of the Lozére; situated on an eminence, near the Lot; before the revolution the see of a bishop; 49 miles W. of Privas. The place contains 5014, and the canton 10,610 inhabitants, on a territory of 305 kiliometres, in ten communes. N. lat. 44° 31′. E. long. 3° 34′.

MENDELI, a fortressed town of the Arabian Irak, on the frontiers of Persia; 50 miles N.E. of Bagdad. N. lat. 33° 54′. E. long. 45°.

MENDELSOHN, Moses, in *Biography*, a Jewish philosopher, and elegant writer in the last century, was born at Dessau, in Anhalt, in the year 1729. His father was a schoolmaster, and undertook the education of his son. He was brought up to business, but devoted every hour he could claim as his own to literature, in which he greatly excelled, and obtained as a scholar a distinguished reputation; but it was, unfortunately, at the expence of his health. He was also destined to a state of extreme penury: at the age of fourteen, he travelled on foot to Berlin, where he lived in indigence and obscurity, and frequently in want of the necessaries of life. At length he got employment from a rabbi as a transcriber of MSS., who, at the same time that he afforded him the means of subsistence, liberally initiated him into the mysteries of the theology, the jurisprudence, and scholastic philosophy of the Jews. The study of philosophy and general literature became from this time his favourite pursuit, but the fervours of application to learning were by degrees alleviated and animated by the consolations

tions of literary friendship. He formed a strict intimacy with Israel Moses, a Polish Jew, who, without any advantages of education, had become an able, though self-taught, mathematician and naturalist. He very readily undertook the office of instructor of Mendelsohn, in subjects of which he was before ignorant, and taught him the Elements of Euclid from his own Hebrew version. "The singular spectacle of the two youthful rabbies, circumstanced as they were, sitting in the corner of retired streets, the one with a Hebrew Euclid, instructing the other, who was hereafter to be classed among the most eminent literati of his country, may instruct the young and the indigent, that the cold touch of poverty can never palsy the sublime efforts of resolute genius." The intercourse between these young men was not of long duration, owing to the calumnies propagated against Israel Moses, which occasioned his expulsion from the communion of the orthodox; in consequence of this, he became the victim of a gloomy melancholy and despondence, which terminated in a premature death. His loss, which was a grievous affliction to Mendelsohn, was in some measure supplied by Dr. Kisch, a Jewish physician, by whose assistance he was enabled to attain a competent knowledge of the Latin language. In 1748 he became acquainted with another literary Jew, *viz.* Dr. Solomon Gumperts, by whose encouragement and assistance he attained a general knowledge of the living and modern languages, and particularly the English, by which he was enabled to read the great work of our immortal Locke in his own idiom, which he had before studied through the medium of the Latin language. About the same period he enrolled the celebrated Lessing among his friends, to whom he was likewise indebted for assistance in his literary pursuits. The scholar amply repaid the efforts of his instructor, and soon became his rival and his associate, and after his death the defender of his reputation, even at the expence of his own life: for when Lessing was charged with Atheism by M. Jacobi, a German writer, he roused all his powers in his justification, and entered so vehemently into the controversy, as to exhaust an already feeble and delicate frame: his whole nervous system became so completely deranged, that severe study, for a short time only, produced fainting fits. To avoid these, when he found them approaching, Mendelsohn would instantly abandon what he was about, and banish all thought from his mind. Being asked how he contrived to exist without thinking, and exercising the powers of reflection, he replied, "I retire to the window and count the tiles upon the roof of my neighbour's house." He died at the age of fifty-seven, highly respected and beloved by a numerous acquaintance, and by persons of very different opinions. When his remains were consigned to the grave, he received those honours from his nation which are commonly paid to their chief rabbies. As an author, the first piece was published in 1755, entitled "Jerusalem," in which he maintains that the Jews have a revealed law, but not a revealed religion, but that the religion of the Jewish nation is that of nature. His work entitled "Phœdon, a Dialogue on the Immortality of the Soul," in the manner of Plato, gained him much honour: in this he presents the reader with all the arguments of modern philosophy, stated with great force and perspicuity, and recommended by the charms of elegant writing. From the reputation which he obtained by this masterly performance, he was entitled by various periodical writers the "Jewish Socrates." It was translated into French in 1773, and into the English in 1789. Among his other works, which are all creditable to his talents, he wrote "Philosophical Pieces;" "A Commentary on Part of the Old Testament;" "Letters on the Sensation of the Beautiful." Gen. Biog.

MENDEN, in *Geography*, a town of Westphalia; 42 miles N E. of Cologne.

MENDES, or MYNDES, a town of Asiatic Turkey, in Natolia, in a bay of the Archipelago; anciently called "Myndus;" 20 miles S. of Milets. N. lat. 33° 5'. E. long. 27° 10'.

MENDES, in *Ancient Geography*, a town of Egypt, near the mouth of one of the eastern branches of the Nile, between Sebennytus to the west, and Tanés to the east. The arm of the Nile on which it was seated was denominated the *Mendesian*. This ancient city was famous for its temples, and the indecency of the worship paid there to the ram. When the sacred animal dies, the Mendesian province solemnizes his death by a general mourning. Herodotus, lib. ii. *Euterpe*.

MENDES, in *Mythology*, an Egyptian deity, who was worshipped as the emblem of the sun. The Egyptians having discovered that they owed the fertility of their country to the influence of the sun, worshipped him under the name of Mendes, which signifies "very fruitful." Accordingly they consecrated the goat to him, as the most prolific of all animals. This animal was fed in the temple of Mendes, as the living image of the God whom he represented. The Greeks gave to Mendes the name of *Pan*; which see.

MENDESCAO, in *Geography*, a town of Naples, in Calabria Citra; 3 miles W. of Cosenza.

MENDEZ, MOSES, in *Biography*, an English poet and dramatic writer, who flourished in the last century, and died about the year 1758. He was of Jewish extraction, though he had abandoned the religion of his fathers. He was author of several poems in Dodsley's Collections.

MENDHAM, in *Geography*, a township of America, in Morris county, New Jersey; six miles W. of Morristown.

MENDICANTI, the title of one of the music schools at Venice for girls, known by the name of conservatorios. The maestro di capella of the hospital de Mendicanti, in 1770, was the worthy Bertoni, by whose favour we were admitted into the interior of this admirable seminary, to an extra concert of two hours, by the best vocal and instrumental performers of this hospital: it was really curious to *see*, as well as to *hear* every part of this excellent concert, performed by females, violins, tenors, bases, harpsichord, French horns, and even double bases; and there was a prioress, a person in years, who presided: the first violin was very well played by Antonia Cubli, of Greek extraction; the harpsichord sometimes by Francesca Rossi, maestra del coro, and sometimes by others: these young persons frequently change instruments. The singing was truly excellent in different styles; and the whole was very judiciously mixed; no two airs of a sort followed each other, and there seemed to be great decorum and good discipline observed in every particular; for these admirable performers, who are of different ages, all behaved with great propriety, and seemed to be well educated. It was here that the two celebrated female performers, the Archiapate, afterwards signora Guglielmi, and signora Maddalena Lombardini, afterwards madame Sirman, who received such great and just applause in England, had their musical instructions.

MENDICANTS, BEGGARS, a term applied to several orders of religious, who live on alms and go a begging from door to door.

The religious society distinguished by this appellation surpassed all the rest in the purity of its manners, the extent of its fame, the number of its privileges, and the multitude of its members. Its order was first established in the 13th century, and the members of it, by the tenor of

their

their inſtitution, were to remain entirely deſtitute of all fixed revenues and poſſeſſions; though in proceſs of time their number became a heavy tax upon the people. Innocent III. was the firſt of the popes who perceived the neceſſity of inſtituting ſuch an order, and accordingly he gave ſuch monaſtic ſocieties, as made a profeſſion of poverty, the moſt diſtinguiſhing marks of his protection and favour. They were alſo encouraged and patronized by the ſucceeding pontiffs, when experience had demonſtrated their public and extenſive uſefulneſs. But when it became generally known, that they had ſuch a peculiar place in the eſteem and protection of the rulers of the church, their number grew to ſuch an enormous and unwieldy multitude, and ſwarmed ſo prodigiouſly in all the European provinces, that they became a burthen, not only to the people, but to the church itſelf. The great inconvenience that aroſe from the exceſſive multiplication of the Mendicant orders was remedied by Gregory X. in a general council, which he aſſembled at Lyons, in 1272. For here all the religious orders, that had ſprung up after the council held at Rome, in 1215, under the pontificate of Innocent III. were ſuppreſſed; and the extravagant multitude of Mendicants, as Gregory called them, was reduced to a ſmaller number, and confined to the four following ſocieties or denominations, *viz.* the Dominicans, the Franciſcans, the Carmelites, and the Auguſtins, or the hermits of St. Auguſtin.

As the pontiffs allowed theſe four Mendicant orders the liberty of travelling wherever they thought proper, of converſing with perſons of every rank, of inſtructing the youth and multitude wherever they went; and as theſe monks exhibited, in their outward appearance and manner of life, more ſtriking marks of gravity and holineſs than were obſervable in the other monaſtic ſocieties, they aroſe all at once to the very ſummit of fame, and were regarded with the utmoſt eſteem and veneration through all the countries of Europe. The enthuſiaſtic attachment to theſe ſanctimonious beggars went ſo far, that, as we learn from the moſt authentic records, ſeveral cities were divided, or cantoned, into four parts, with a view to theſe four orders; the firſt part being aſſigned to the Dominicans, the ſecond to the Franciſcans, the third to the Carmelites, and the fourth to the Auguſtinians. The people were unwilling to receive the ſacrament from any other hands than thoſe of the Mendicants, to whoſe churches they crowded to perform their devotions, while living, and were extremely deſirous to depoſit there alſo their remains, after death; nor did the influence and credit of the Mendicants end here; for we find in the hiſtory of this, and of the ſucceeding ages, that they were employed, not only in ſpiritual matters, but alſo in temporal and political affairs of the greateſt conſequence, in compoſing the differences of princes, concluding treaties of peace, concerting alliances, preſiding in cabinet councils, governing courts, levying taxes, and other occupations, not only remote from, but abſolutely inconſiſtent with, the monaſtic character and profeſſion. However, the power of the Dominicans and Franciſcans greatly ſurpaſſed that of the other two orders; inſomuch that theſe two orders were, before the Reformation, what the Jeſuits have been ſince that happy and glorious period, the very ſoul of the hierarchy, the engines of the ſtate, the ſecret ſprings of all the motions of the one and the other, and the authors and directors of every great and important event, both in the religious and political world. By very quick progreſſion their pride and confidence arrived at ſuch a pitch, that they had the preſumption to declare publicly, that they had a divine impulſe and commiſſion to illuſtrate and maintain the religion of Jeſus; they treated with the utmoſt inſolence and contempt all the different orders of the prieſthood; they affirmed, without a bluſh, that the true method of obtaining ſalvation was revealed to them alone; proclaimed, with oſtentation, the ſuperior efficacy and virtue of their indulgences; and vaunted, beyond meaſure, their intereſt at the court of heaven, and their familiar connections with the Supreme Being, the Virgin Mary, and the ſaints in glory. By theſe impious wiles, they ſo deluded and captivated the miſerable and blinded multitude, that they would not entruſt any other but the Mendicants with the care of their ſouls. They retained their credit and influence to ſuch a degree, towards the cloſe of the 14th century, that great numbers of both ſexes, ſome in health, others in a ſtate of infirmity, and others at the point of death, earneſtly deſired to be admitted into the Mendicant order, which they looked upon as a ſure and infallible method of rendering heaven propitious. Many made it an eſſential part of their laſt wills, that their bodies after death ſhould be wrapped in old ragged Dominican or Franciſcan habits, and interred among the Mendicants. For ſuch were the barbarous ſuperſtition and wretched ignorance of this age, that people univerſally believed, they ſhould readily obtain mercy from Chriſt, at the day of judgment, if they appeared before his tribunal aſſociated with the Mendicant friars.

About this time, however, they fell under an univerſal odium; but being reſolutely protected againſt all oppoſition, whether open or ſecret, by the popes, who regarded them as their beſt friends, and moſt effectual ſupports, they ſuffered little or nothing from the efforts of their numerous adverſaries. In the 15th century, beſides their arrogance, which was exceſſive, a quarrelſome and litigious ſpirit prevailed among them, and drew upon them juſtly the diſpleaſure and indignation of many. By affording refuge, at this time, to the Beguins in their order, they became offenſive to the biſhops, and were hereby involved in difficulties and perplexities of various kinds. They loſt their credit in the 16th century by their ruſtic impudence, their ridiculous ſuperſtitions, their ignorance, cruelty, and brutiſh manners. They diſcovered the moſt barbarous averſion to the arts and ſciences, and expreſſed a like abhorrence of certain eminent and learned men, who endeavoured to open the paths of ſcience to the purſuits of the ſtudious youth, recommended the culture of the mind, and attacked the barbariſm of the age in their writings and diſcourſe. Their general character, together with other circumſtances, concurred to render a reformation deſirable, and to accompliſh this happy event. Moſheim's Eccl. Hiſt. vol. iii. paſſim.

Among the number of Mendicants are alſo ranked the Capuchins, Recollects, Minims, and others, who are branches or derivations from the former.

MENDING, in *Agriculture*, a term uſed to ſignify the improving of land by means of manure.

MENDIP Hills, in *Geography*, a range of hills, in the county of Somerſet, near the city of Wells; celebrated for mines of lead and coals.

MENDLING, a town of Auſtria, on a river of the ſame name, which runs into the Salza, near Keifling, in Stiria; the town is 15 miles diſtant S.S.E. from Bavarian Waidhoven.

MENDOCINO, Cape, a cape of North America, on the coaſt of New Albion; off the cape lie ſome rocky iſlets and ſunken rocks, about a league from the ſhore. This cape is rendered remarkable by being the higheſt on the ſea-ſhore of this part of New Albion. The mountains behind it are elevated and break into ſeparate hills, riſing abruptly

abruptly and divided by many deep chasms. On both the hills and chasms are some few dwarf trees. The general surface exhibits vegetables of a dull green colour, interspersed with perpendicular strata of red earth or clay. N. lat. 40° 19'. E. long. 135° 53'.

MENDOLCIA, a town of Naples, in Calabria Citra; three miles W. of Bova.

MENDON, a post-town of America, in Worcester county, Massachusetts; 37 miles S.W. of Boston. The township, called "Quanshipauga" by the Indians, was incorporated in 1667, and contains two congregational parishes, a society of Friends, and 1628 inhabitants. On the S. it is bounded by the state of Rhode island; and it is watered by the Charles and Mills rivers, and other streams, which turn several mills.

MENDOW, a town of Hindoostan, in Guzerat; 33 miles E. of Amedabad.

MENDOZA, Don Inigo Lopez de, Senor de Hita y Buytrago, first marques de Santillana, and Conde del Real de Manzanares, in *Biography*, was born in August 1398; he married in 1418 Dona Catalina de Figueroa, and died in 1458. During the reign of Juan II. his courage was conspicuous, and his prudence still more so, as he aggrandized himself without injuring his reputation. He is mentioned not only as a contributor to the literature of his own country, but as an early patron of it. His works are as follow: 1. Maxims of morality in verse, written by desire of Juan II. for the instruction of his son Henrique. This book has passed through ten editions at least, and is still reckoned one of the rarest in that language. 2. Proverbs which old women repeat by the fire-side: this is supposed to be the oldest collection of proverbs in any modern language. 3. A letter addressed to D. Pedro, son of the Infante D. Pedro of Portugal. This letter, which the marques sent with a collection of his own poems, is regarded as one of the most valuable documents for the literary history of Spain, as containing an account of all the Spanish poets, whose works the writer had either seen or heard of. Besides these, many of the marques' poems are in the "Cancionero General," and others in MSS.: among them is a poem upon the "Creation," consisting of 333 stanzas, in the same metre as the "Trezientas" of Mena, which see. He first introduced the sonnet into Spanish poetry.

Mendoza, D. Diego Hurtado de, son of Lopez de Mendoza, first marques de Mondejar, was born at Granada about 1503, and there, during his childhood, he acquired a practical knowledge of Arabic, which he continued to cultivate through life. He studied the Greek language very successfully at Salamanca, and was a soldier in the Italian wars. While engaged in the military service, he spent every winter, while the troops were inactive and in quarters, at Rome, or Padua, or some other Italian university, where he could enjoy and profit by the society of learned men. He was employed as ambassador by Charles V. in the most important transaction of his whole reign, at the council of Trent, at Venice, and at the papal court. At Venice he exerted himself to recover Greek MSS. He obtained many of the writings of St. Basil the Great, and of Gregory Nazianzen, the works of Cyril of Alexandria, and the more valuable remains of Archimedes, of Hero and of Appian: all these, with copies also of cardinal Besarion's and of other collections, he left to the Escurial library. Don Diego was superseded at Rome in 1551 to satisfy the papal court. He continued some years one of Philip's counsellors, but was at length banished from his court. He retired to Granada, and there upon the spot composed his history of the war against the Moriscoes: here he amused himself with literature during the remainder of his life. In 1574 he obtained leave to return to Madrid, and died in a few days after his arrival. None of his works were published during his lifetime. In 1610 a volume of his poems was collected by J. D. Hidalgo, the king's chaplain, who suppressed the comic and satiric pieces, which were numerous. His history of the Moriscoes was published the same year by Luis Tribaldos; part of the third book having been lost, was supplied by the count de Portalegre, D. Joam de Silva. It has been reprinted several times, and is reckoned the very best specimen of historical composition in the Spanish language. The story of Lazarillo de Tormes, which has been translated into almost every European tongue, is attributed to this author as a youthful work, written at Salamanca. Others impute it to Juan de Ortega. Gen. Biog.

Mendoza, Peter Gonzalez de, a Spanish cardinal, and archbishop of Toledo, was born in 1428. He acquired his high preferments in the church by his talents as a statesman. Pope Sixtus IV. made him cardinal. He died in 1495: as a literary man he is said to have translated the Iliad and Æneid, also Sallust, into the Spanish. Another person of the same name, an Augustine friar, was sent by the king of Spain as ambassador to the emperor of China in 1584. After obtaining several instances of preferment, he was appointed, in 1608, bishop of Popayan in the West Indies. He is known as an author by a history of China, written in the Spanish language. Moreri.

Mendoza, in *Geography*, a jurisdiction of Chili, in South America, subject to the vice-royalty of Buenos Ayres. It has a town of the same name, which lies on the E. side of the Cordilleras, about 50 leagues from Santiago. It is situated on a plain, adorned with gardens, and supplied with water by means of canals. The town contains about 100 families, half Spaniards and half Indians, together with a college founded by the Jesuits, a parochial church, and three convents. This jurisdiction comprehends also the towns of St. Juan de la Frontera, on the E. of the Cordilleras, and about 30 leagues N. of Mendoza, and St. Louis de Loyola, about 50 miles E. of Mendoza; the latter is small, but has a parish church, a Dominican convent, and a college founded by the Jesuits. S. lat. 33° 25'. W. long. 69° 47'.

Mendoza, a river which rises in the Cordilleras of the Andes; over which is a natural bridge of rocks, from the vaults of which hang icicles, formed of the water as it drops from the rocks. The bridge is broad enough to admit of three or four carts abreast. Near it is another bridge, called the bridge of the Incas, betwixt two rocks, and elevated a great height from the river.

MENDRA, a small island in the Indian sea, near the coast of Africa. S. lat. 2° 15'.

MENDRAH, a town of Fezzan, in a district or province of the same name, nearly S. from Mourzouk, and distant from it about 60 miles. Although much of the land is a continued level of hard and barren soil, the quantity of "Troua," a species of fossil alkali that floats on the surface, or settles on the banks of its numerous smoaking lakes, has given it a higher importance than that of the most fertile districts. Of this valuable produce, great quantities are annually brought by the merchants of Fezzan to Tripoli, from whence it is shipped for Turkey and Tunis, and the dominions of the emperor of Morocco. The people of the latter employ it as an ingredient in the dye of the leather, for which they are famous, and in that of the woollen caps that are worn by the Arabs and the Moors as the basis

of

of their turbans. Proceedings of the African Association, &c. 1790.

MENDRISIO, or MENDRIS, a small well-built market-town of Italy, in the department of the Verbano, late the capital of a small bailiwick of the same name, lying between the lakes of Como and Lugano, which is extremely fertile, and contains 19 parishes, and about 16,000 inhabitants. The town is about 26 miles N.N.W. of Milan, and 7 miles from Como. N. lat. 45° 45′. E. long. 9° 0′.

MENDURAGU, a town of Russia, in the government of Viburg, on the borders of Finland; 48 miles W.N.W. of Velmanstrand.

MENEDEMUS, in *Biography*, a Greek philosopher, who flourished towards the close of the fourth century before Christ, was a native of Eretria, in the island of Eubœa. He was of the ELIAC *School* (which see), which he afterwards transferred to his native city, and gave it the name of *Eretrian*. Menedemus, though nobly descended, was obliged, through poverty, to submit to a mechanical employment, either as tent-maker or mason. He formed an early intimacy with Asclepiades, who was a fellow-labourer with him in his humble occupation. Having minds more adapted to study than manual labour, they resolved to devote themselves to the pursuit of philosophy. For this purpose, they left their native country, and went to Athens, where Plato presided in the academy. (See ASCLEPIADES.) In his own school at Eretria he neglected those forms which were commonly observed in places of this kind, and allowed his hearers and disciples to attend him in whatever posture they pleased, standing, walking, or sitting. At first Menedemus was received by the Eretrians with great contempt; and, on account of the vehemence with which he disputed, obtained the appellations of "Cur" and "Madman." But he afterwards rose into high esteem, and was entrusted with a public office, to which was annexed an annual stipend of 200 talents. He discharged the trust with fidelity and reputation, but accepted only of a fourth part of the salary attached to the appointment. He was sent upon several embassies to Ptolemy, Lysander, and Demetrius, and rendered his countrymen essential services, by obtaining a diminution of their tribute, and rescuing them from other burdens. Antigonus entertained a personal respect for him, and professed himself one of his disciples. His intimacy with this prince created a suspicion among his countrymen, that he had a secret intention to betray their city into his hands. To save himself he fled to Antigonus, and soon after died, in the eighty-fourth year of his age. It is thought he precipitated his end by abstaining from food for several days, being oppressed with grief, as well on account of the ingratitude of his countrymen, as on his disappointment in not being able to prevail on Antigonus to restore the lost liberties of his country. Menedemus possessed great talents as a philosopher and disputant. He declared his opinions with freedom, inveighed with severity against the vices of others, and, by the purity of his own manners, commanded universal respect. He observed the strictest moderation in the manner of his living. His entertainments, which were frequented by many philosophers and men of distinction, were simple and frugal, consisting chiefly of vegetables. Enfield's Hist. vol. i.

MENEDEMUS, a Cynic philosopher, was a native of Lampsacus, who lived during the reign of Antigonus, king of Macedon. At this period, the peculiarities of the Cynic sect had been carried to an absurd and ridiculous extreme. In Menedemus, the spirit of the sect was degenerated to downright madness: at first, its members being no more than severe public monitors, commanded attention and respect, but their freedom in censuring had degenerated into scurrility, and the conduct of Menedemus surpassed, in folly and extravagance, every thing that had gone before him. He appeared in public dressed in a black cloak, with an Arcadian cap upon his head, on which were drawn the figures of the twelve signs of the zodiac, with tragic buskins on his legs, with a long beard, and with an ashen staff in his hand, exclaiming, that he was a spirit returned from the infernal regions to admonish and reform the world. Enfield's Hist. Phil.

MENEHOULD, ST., in *Geography*, a town of France, and principal place of a district, in the department of the Marne. The place contains 3394, and the canton 12,820 inhabitants, on a territory of 437½ kiliometres, in 30 communes. The town is situated in a morass between two rocks, on the highest of which is a castle; 22 miles E.N.E. of Chalons. N. lat. 49° 5′. E. long. 4° 55′.

MENEJRE, a town of Arabia, in Yemen; 34 miles S.E. of Loheia.

MENELAUS, in *Biography*, king of Sparta, famous in ancient history for the share which he took in the Trojan war, was son of Atreus, king of Argos, and brother of Agamemnon. He married Helen, the daughter of Tyndarus, king of Sparta, and in her right succeeded to the crown of that country. According to the best account of the origin of the Trojan war, Paris, son of Priam, induced by the fame of Helen's beauty, paid a visit to the court of Menelaus, where he was most hospitably received. During his stay, Menelaus was obliged to take a voyage to Crete, and Paris made use of this opportunity to carry off Helen, together with all the treasure and rich moveables he could lay his hands upon. This injury was made a common cause by the petty kings of Greece, who, with a powerful army under the command of Agamemnon, laid siege to Troy. Menelaus was present as a leader of the confederates. In the tenth year of the Trojan war, Helen obtained the forgiveness and favour of Menelaus, by introducing him with Ulysses, the night that the city was reduced to ashes, into the chamber of Deiphobus, whom she had married after the death of Paris. This perfidious conduct totally reconciled her to her first husband, and she returned with him to Sparta, where Telemachus is represented in the Odyssey as finding them living in peace and prosperity. Menelaus is said to have been succeeded in this kingdom by two illegitimate sons, who were expelled by Orestes, son of Agamemnon. The palace which Menelaus once inhabited was entire in the days of Pausanias, as well as the temple which had been raised to his memory by the people of Sparta. Homer. Univer. Hist.

MENELAUS, a celebrated mathematician, who flourished under the reign of the emperor Trajan, was of Grecian extraction, but a native of Alexandria. He is called by Ptolemy a geometrician, as having made astronomical observations at Rome in the year 98 of the Christian era. He is supposed to have been the Menelaus referred to by Plutarch in his dialogue "De Facie quæ in orbe Lunæ apparet." He was author of three books "On Spherics," which have come down to the present times through the medium of the Arabic language. A Latin version of this work was published at Paris by father Mersenne, in 1664, with corrections, restorations, and additional illustrative propositions. Gen. Biog.

MENELAUS, called also *Menelaites*, in *Ancient Geography*, a town of Egypt, and capital of a nome called *Menlaites* by Pliny. According to Strabo, Menelaus is not far from the nome of Nitria.—Also, a town of Africa, in Marmarica,

rica, placed by Ptolemy in the interior of the country between Leucæ and Gaphara.

Menelaus, in *Geography*, a town of Africa, in Barca; 105 miles E.S.E. of Cureu. N. lat. 32° 10′. E. long. 23° 10′.

MENENIUS, in *Biography*. See Agrippa.

MENERANDRE, in *Geography*, a river on the S. coast of Madagascar, which runs into the sea, S. lat. 25° 5′. E. long. 42° 24′.

MENERBES, a town of France, in the department of the Mouths of the Rhone; 9 miles S.W. of Apt.

MENEROLA, a town of Genoa; 5 miles S.W. of Spezza.

MENES, in *Biography*, the founder of the Egyptian empire, was born at This, a town of Thebais, in Upper Egypt. He is supposed to have reigned 117 years after the birth of Phaleg, son of Heber, which was the year of the dispersion of the people throughout the earth. He built the town of Memphis, and in the prosecution of his work stopped the course of the Nile near it, by constructing a causeway several miles broad, and caused it to run through the mountains. By his ability and popularity he was deified after his death. He had three sons, who ruled after him, *viz*. Athotis, who ruled at This and Thebes; Curudes, who founded the kingdom of Heliopolis, afterwards the kingdom of Diospoli; and Necherophes, who reigned at Memphis.

MENESTREL, a musician, whose name and employment have been recorded by Pithou in his "History of the second Race of Kings of France," who tells us, that it was during the reign of Pepin that the chapel royal was established at Paris, under a music-master named Menestrel; which, perhaps, may have been the origin of the name of Menestrel, or Minstrel, being given, in after times, to musicians in general. Pepin died in 768.

Menestrels were the singers, and *Menetriers* the instrumental performers in France, who, in the time of king Robert, formed themselves into a society of musicians, in imitation of the ancient bards; they composed and executed the music to the poetry of the *trouvers*, *troubadours*, or *romancers*, who composed poems in rhyme. Others were called *jongleurs*, and *chantores* or *menestrels*.

In a tarif of St. Louis to regulate the toll at the entrance into Paris, it is said that the jongleurs should be excused paying the toll, upon condition that they sung a song, (hence, perhaps, the proverb of paying for any thing with a *song*), or made their monkies dance, (whence, probably, the French have derived another proverb, "payer en monnoie de singe.")

MENESTRIER, John Baptist le, in *Biography*, an able antiquary, was born at Dijon in 1564. He obtained some considerable offices at court, but is particularly known by a work entitled "Medailles, Monnoies, et Monumens antiques d'Imperatrices Romaines." This was published in 1625: the author died in 1634, and in 1642 a posthumous work was given to the world by his friends, under the title of "Medailles illustres des anciens Empereurs et Imperatrices de Rome." Neither of these works is in much esteem by modern medallists.

Among the curious works of this ingenious Jesuit, his treatises on representations in music, and on ballets, or stage-dances, ancient and modern, should be consulted by those who read, as well as those who write histories of music and dancing: as the information they contain is original, and such as no other books can supply.

John Baptist le Menestrier, the learned antiquary of Dijon, who died in 1634, was an ancestor of the ecclesiastic, and had the same singular passion for science and curious inquiries. He wrote on medals, coins, ancient monuments, on the Roman empresses, &c. Being buried in the church of St. Medard, in Dijon, the following extraordinary epitaph was formerly legible on his tomb-stone:

"Cy git Jean le Menestrier,
L'an de sa vie soisante-dix
Il mit le pied dans l'estrier,
Pour s'en aller en Paradis."

"Here John le Menestrier was put,
At threescore years and ten, precise;
Who then in stirrup placed his foot,
To go full speed to Paradise."

Menestrier, Claude le, also of Dijon, and a contemporary of the preceding, was likewise attached to the study of antiquity, and became keeper of the Barberini Museum. He is author of "Symbolica Dianæ Ephesiæ Statua explicata," 4to. published in 1657. Moreri.

Menestrier, Claude Francis, a Jesuit known by his works on heraldry, &c. was born at Lyons in 1631. He entered, at an early age, into the society of the Jesuits, where he acquired a great knowledge of the ancient languages, and of literature in general. As he advanced in life, he devoted himself chiefly to the study of history, with all that relates to family distinctions, and the monuments of antiquity. He travelled into most of the countries of Europe, and by the knowledge which he acquired, he was enabled to make a figure in theological disputations, and in pulpit oratory. He was, however, particularly famous for his talents in planning and arranging all kinds of festive exhibitions, sacred and profane, from the entry of a prince to the canonisation of a saint. In his designs, devices, and inscriptions, his invention was inexhaustible. He had a great acuteness in decyphering old and mutilated inscriptions, blazoning coats-of-arms, explaining paintings and sculptures, and in all operations of antiquarian science. He died in 1705, at the age of seventy-four. The principal works of this author were, 1. "Histoire Civile ou Consulaire de la Ville de Lyon;" "Eloge Historique de la même Ville;" "L'Histoire du Regne de Louis le Grand par les Medailles, Emblemes, Devises, &c.;" "Methode du Blason;" "La Philosophie des Images:" besides these, however, he wrote a number of smaller pieces on similar topics. Moreri.

MENETOU-Salon, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges; 9 miles N. of Bourges. The place contains 3277, and the canton 10,873 inhabitants, on a territory of 367½ kiliometres, in 11 communes.

MENETOUS, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Romorantin; 8 miles S.E. of Romorantin. The place contains 824, and the canton 4794 inhabitants, on a territory of 240 kiliometres, in 10 communes.

MENEZES, in *Biography*. This is the name of the Condes de la Ericeira, a noble house in Portugal, in which the love of literature, united with considerable talents, continued to be hereditary for many generations. In the General Biography, the most celebrated persons are mentioned, with their principal works, in one article. To this we shall be indebted for the following account. The first of the family distinguished for literary talents was Don Diego, who, in 1628, published "Vida de D. Henriquede Menezes Governandor de la India," 4to. Madrid. The second distinguished person was Don Fernando, whose chief publications were,

were, 1. "Historiarum Lusitanarum libri decem ab anno 1640, usque ad annum 1656." 2. "Historia de Tangere," folio, Lisboa, 1732. 3. "Vida de el Rey D. Joam I." His brother, son-in-law, and heir, Don Luiz, published a still more valuable work than any of the foregoing, under the title of "Historia de Portugal Restaurado." The wife of Don Luiz kept up the credit and fame of the family as an author, and it has been said of her, that "she wrote not with the quill of an eagle, for of such there are many;—but with the quill of a Phœnix, of which there is but one." This lady, as we have hinted, belonged to the family by blood, as well as marriage, having married her father's brother. Don Francisco Xavier, the son of this marriage, left behind him forty-four works, of which the most known and celebrated is the "Henriqueida, Poema Heroico, em doze Cantos," 1741. The Conde, Don Henrique, founder of the royal house of Portugal, is the hero of the piece. It appears that the author of this work, at the age of eight, was member of one academy, which seems by its title to have been designed for extemporary speaking; and, when a little older, was admitted into another, of which, at twenty, he was president. This, says his biographer, was the age of academies in Portugal: he was secretary and protector of the Portuguese, and censor and director of the royal one; a member of the Arcadians of Rome, and of our own Royal Society. He had as correspondents the most learned men in the different nations of Europe. He says in his preface, that the knowledge which he has of Greek is not sufficient for him to understand Homer well, a proof how little that language was cultivated in his country, when the most learned man in it would make such a declaration: in other respects, this preface discovers a range of poetical reading which few have equalled, and none, perhaps, exceeded. The poem itself is not worse than its French name-sake, though its faults are of a different character. He was blind when he wrote it, and died before it was published. This truly estimable man was the munificent patron of letters. He increased the family library with 600 MSS., and 20,000 volumes.

"This vein was not yet exhausted; Don Luiz, the fifth Conde, wrote commentaries of his own administration in India, corrections, and a supplement to Bluteau's Portuguese dictionary, and also to Moreri. He completed the catalogue of the library which his predecessor had begun: it was one of the noblest which any private family ever collected together, but it has been dispersed, and I (Mr. Southey), who write, have purchased some volumes from its wreck at the stalls in London. Portuguese literature is deeply indebted to this noble house. Individuals have succeeded better, but no family has ever done so much." Gen. Biog.

MENF, in *Geography*. See MEMPHIS.

MENFRICI, a town of Sicily, in the valley of Mazara, containing about 2700 inhabitants; 9 miles N.W. of Sacca.

MENFUS KEDDUS, a town of Abyssinia; 60 miles S.S.E. of Siré.

MENGEN, a town of Wurtemberg, insulated in the county of Scheer; 33 miles S.W. of Ulm. N. lat. 48° 3′. E. long. 9° 23′.

MENGENGUT, a town of Prussia, in the province of Oberland; 12 miles E. of Osterrod.

MENGERINGHAUSEN, a town of Germany, in the county of Waldeck; 24 miles W.N.W. of Cassel.

MENGERSDORF, a town of Germany, in the principality of Culmbach; 13 miles S. of Culmbach.

MENGERS-KIRCHEN, a town of Germany, in the county of Nassau-Dillenburg; 7 miles S.W. of Dillenburg.

MENGESTA SEMAIAT, a town of Abyssinia; 165 miles S. of Gondar.

MENGOLI, PETER, in *Biography*, was an able Italian mathematican in the 17th century, concerning the place and time of whose birth there is no trace. He studied mathematics under Cavalieri, to whom the Italians ascribe the invention of the first principles of the infinitesimal calculus. Mengoli was appointed professor of "Mechanics," in the college of nobles at Bologna, and acquired high reputation by the success with which he filled that post. His principal works are, "Geometriæ Speciosæ Elementa;" "Novæ Quadraturæ Arithmeticæ, seu de additione Fractionum;" "Via regia ad Mathematicas ornata;" "Refrazzione e paralasse Solare;" "Speculationi de Musica;" "Arithmeticæ rationalis Elementa;" "Arithmetica realis." Moreri.

His "Speculationi di Musica," a desultory and fanciful work, was published at Bologna, 1670. An account of this treatise was given in the Phil. Tranf. vol. viii. N° c. p. 6194. seemingly by Birchensha, who, at the close of the article, has not forgotten himself, or his own interest. The speculations contained in Mengoli's work are some of them specious and ingenious; but the philosophy of sound has been so much more scientifically and clearly treated since its publication, that the difficulty of finding the book is no great impediment to the advancement of music. He was still living in 1678.

MENGRAVILLA, in *Geography*, a town of Spain, in Old Castile, famous for its mines of salt: near Avila.

MENGS, ANTHONY RAPHAEL, in *Biography*, was born on the 12th of March, 1728, at Aussig, in Bohemia. His father, whose name was Ismael, was a miniature and enamel painter, and dedicated his son to the art from his birth: hence he had him christened after the names of *Anthony Allegri da Correggio*, and *Raphael d'Urbino*. His first studies were of course under the eye of his father, who from his earliest childhood obliged him to labour with his pencil; and as soon as possible gave him information of geometry and chemistry, in which sciences he became the most intelligent artist in Europe. Seeing that his son pursued his studies with a reflective mind, Ismael justly concluded, that it would be right at once to introduce him to the fountain head of the art, and lay before him the purest models for his study; and, therefore, at the early age of 12, he took him to Rome, and there introduced him to the works of M. Angelo, Raphael, &c. &c. Young Mengs was so far advanced in the art as to be capable of relishing the superior productions now laid open before him; prints and drawings from which he had long been accustomed to copy: and was eagerly desirous of persevering in the laudable desire of imitating them. At first, his father confined him to drawing in crayons from the Laocoon, the Torso, and the works of M. Angelo; and afterwards from those of Raphael. This most excellent system of education he himself thwarted, by enacting too much and too minute an imitation, and too long confinement to that alone; at a time when, if the vivid fancy of youth had been permitted to indulge itself, Mengs might have imbibed the spirit which animates, which governs the compositions of those great labours which were before him, instead of dwelling on the surface, and forgetting the object of the whole; which is, or should always be, the prime end in view in all studies made upon the works of others. That he was capable of all this fully appears by what he did, particularly by his future reasonings (which are published) upon the works of the principal painters; and that he did not do it effectually, equally appears by his paintings; which possess more of the character of the lines and composition observable in the works of Raphael, who was his favourite, than his just perception of of point and interest in a story, and the true pathos with which he selected incidents, and gave expression and grace to his figures.

It was only for three years that his father, who was extremely tyrannical and arbitrary, allowed him to stay at Rome, at the end of which time, probably being anxious to turn his son's talents to account, he obliged him to return with him to Dresden, where all this excellent preparation was debased, by our artist being employed to paint portraits in crayons; by which, however, he became known to, and employed by, the king of Poland, who made him his cabinet painter, gave him a house and a pension, without any other obligation, than to give him the preference of those works he might perform, and for which he would pay the full price.

With this good fortune he returned to Rome to prosecute his studies; at first copying, but at length beginning to compose his own pictures. About this time he married a young lady of a respectable family, Margarita Guazzi, and was in hopes of being permitted finally and fully to establish himself in Rome; but his father, at the end of four years, again, in 1749, forced him to return to Dresden, and in pursuance of his arbitrary feeling quarrelled with him, seized his whole property, and turned him out of doors.

His talents were now his only safeguard and support, and, to the honour of the king, proved truly so. His majesty patronized him, gave him a house and a carriage, appointed him his first painter, and doubled his pension, without any obligation, and permitted him again to visit Rome.

His first work there was a copy of the school of Athens by Raphael, for the earl of Northumberland, which is now at Northumberland House. The failure of affairs at the court of Saxony and Poland, which happened soon after, caused a stoppage of his pension, threw Mengs upon the world, and induced him to accept many commissions for pictures; the principal one of which, a fresco ceiling in the church of the Augustines, dedicated to St. Eusebius, acquired him great reputation, and some employment of the like nature in the villa Albani; where he painted in fresco Apollo, and the Muses on Parnassus.

Some pictures which Mengs had executed acquired him the favourable regard of the king of Naples, who, upon becoming king of Spain under the title of Charles III., sent for him to Madrid, offering him a ship of war to convey him, a salary of 2000 doubloons, a house, a carriage, and to defray all the expences attending his professional labours. This munificent offer was readily accepted, and Mengs arrived in Spain in October 1761. The king received him with great kindness, and continued the same attention to him all the while he remained in that country, which was several years. He executed a great number of pictures both in fresco and in oil, which were highly admired and applauded by the court, but were criticised by some, as being too cold aud phlegmatic in their style and expression.

Excess of study, and disgust at the harsh conduct of some of his contemporaries, affected his health; and being deprived of the benefit of domestic enjoyment, having sent his family to Rome, he fell into despondency, and a decline approaching, his life was despaired of, when he obtained permission to return to Rome, still enjoying his pension as first painter to the king.

His health and spirits were soon re-established in his favourite residence, and he was employed by Clement XIV. to paint in the Vatican; particularly in the cabinet where the ancient papirii were preserved. He prolonged his stay in Italy as long as he could, though advised by his friend the chevalier d'Azara, the Spanish minister at Rome, that his return to Spain was looked for by the king, by whose command he was at last obliged to go there again. He took part of his family with him, and remained there two years and a little more, painting many things; and again becoming exhausted and ill, too ill to prosecute his labours, his majesty left him at full liberty to return, with his pension of 3000 scudi, and 1000 more to divide in dowers among his daughters.

He had not been long in Rome when he lost his wife, which severe affliction entirely changed his mind and manners, and rendered him morose and unhappy, a scourge to himself and those around him. His old disease returned upon him, and in a short time afterwards he paid the debt of nature, having only attained the age of 51.

If the fame and qualifications of Mengs had not been so extravagantly exalted by his friend and commentator Azara, and by Winkelmann, it is most likely his memory would have been in more esteem with the world than it now is. But when they resorted, in speaking of his talents, to such a degree of absurdity, as to place him above all competitors, either ancient or modern; to speak of him as the man for whom it was reserved to unite all the excellencies of art, criticism is excited, and a more scrupulous and less prejudiced examination induced, which bestows upon our artist a far less exalted rank among those great men with whom he has been compared, and even to whom he has been preferred, than his partial and prejudiced friends allotted to him. He certainly was the most ingenious professor they were acquainted with. His long and laborious researches into the more obscure matters relating to art, and his careful and even enthusiastic examination of the works of the ancients, and consequent knowledge of them, rendered him in their eyes, who do not appear to have had so much taste as enthusiasm, a kind of demi-god. But it is not researches and knowledge of this nature which make the artist; they will indeed assist him with principles and materials, they will present compositions, and fill vacant spaces upon a canvas, or on a wall, with something agreeable to, or imposing upon, the eye; but if the soul be wanting, if the true perception of that which alone stimulates the feeling heart and understanding mind, impress not its energy upon the observer, the artist is but a mechanic, whose studies happen to have fallen into a more side-long track than those of the generality; or at most he may be saluted with the title of the man of science, never in comparison with the truly great artists will he merit their distinguishing appellation.

These remarks are justly applicable to Mengs, who, though a very ingenious and extraordinary man, is but a tame and rather uninteresting artist. Mr. Cumberland, in his memoirs of painters in Spain, has given a very excellent and just critique upon his merits, which we will here transcribe. He was excited to it by a remark of Mengs upon the discourses of sir J. Reynolds, in which that artist observes, that "those discourses would lead youth into error, because they abandon them to superficial principles, the only ones known to the author." After some little petulancy exhibited in the former part of his answer to this remark, Mr. Cumberland says, "that Mengs was an artist that had seen much and invented little; that he dispenses neither life nor death to his figures, excites no terror, rouses no passions, and risks no flights; that, by studying to avoid particular defects, he incurs general ones, and paints with tameness and servility; that the contracted scale and idea of miniature painting to which he was brought up, is to be traced in all or most of his compositions, in which a finished delicacy of pencil exhibits

hibits the hand of the artist, but gives no emanation of the soul of a master; if it is beauty, it does not warm; if it is sorrow, it excites no pity." The picture of our Saviour's appearing to Mary Magdalen in the garden, known by the name of *The Noli me tangere*, which is in the chapel of All Souls' college, Oxford, will enable our readers to judge how far these remarks are founded in truth.

As a critic, Mengs has a more fair claim to attention. He certainly entertained sublime ideas of the capabilities of art, and therefore inspires them in the minds of his readers. There is, however, too great a mixture of metaphysics and subtle disquisition in his writings, to be generally useful. His explanations of beauty and taste are extremely vague. The former is built entirely upon the Platonic system of the beauty of goodness. On this, however, he proposes material selection from various objects of the same kind, to produce the beautiful of each species, and this choice he completely confounds with taste. Notwithstanding these defects, his writings convey much useful matter, and present many important points, for the consideration of an artist; as they embrace all the essential principles of the art of painting. They were published after the death of Mengs, by his friend the chevalier d'Azara; who also mentions that all the technical parts of Winkelmann's history of the arts are written by Mengs.

MENHAIA, in *Geography*, a town of Fez, in the province of Chaus, inhabited by Arabs.

MENHUSS, a town of Africa, in the country of Barca; 160 miles S.W. of Tolomata.

MENIAL SERVANTS. See SERVANTS.

MENIAN COLUMN. See COLUMN.

MENIE', in *Geography*. See MINIET.

MENIF, or MENUF, a town of Egypt, and chief place of a district; 28 miles N. of Cairo.

MENIGOUTTE, a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Parthenay; 11 miles S.S.E. of Parthenay. The place contains 880, and the canton 7101 inhabitants, on a territory of 240 kiliometres, in 10 communes.

MENIL, a town of the Arabian Irak, on the Tigris; 110 miles S.E. of Bagdad.

MENILITE; *Menilit*, Wern.; *Leber-Opal*, Karst.; *Quarz-résinite menilite*, Haüy.

The colour of this fossil, on the planes of fracture, is between chesnut and liver-brown, passing into hair-brown, and into greyish-yellow; externally the brown variety possesses a blueish tarnish, owing to closely adhering particles of the matrix in which it is found.

It occurs in knob-shaped or tuberose imbedded masses, and in amorphous tuberculated pieces, with rough dull surface.

Internally it is glistening, passing into shining; lustre sometimes resinous.

Longitudinal fracture coarse splintery, passing into flat conchoidal; transversal fracture flat conchoidal, more or less in a parallel direction; fragments indeterminately angular and sharp-edged, translucent on the edges. It yields a greyish-white streak.

Not very hard; hardness that of the semiopal; brittle, easily frangible. Spec. grav. 2.185, Klapr.; 2.162, Jordan.

It is infusible before the blowpipe, but becomes of a lighter colour, opaque, and flawed. With borax it fuses slowly, and with some ebullition. According to Klaproth's analysis of the menilite, a hundred parts are composed of

Silica - - -	85.50
Argil - - -	1.00
Lime - - -	0.50
Oxyd of iron - -	0.50
Water and carbonaceous matter	11.00
	98.50

It is found near Paris, the darker variety at Menil-Montant, the lighter or greyish at Argenteuil; at both places under a thick bed of clay, in a particular kind of slate, called *Klebschiefer* by Werner, or *adhesive slate*. According to Haüy it also occurs on the banks of the Maas. A blackish-green fossil, agreeing in most of its characters with menilite, and likewise in being found imbedded in adhesive slate, is met with at Zamuto, in the district of Semplin, in Hungary.

This fossil was first referred by Werner to the semiopal; and Karsten still enumerates it as a particular subspecies of opal, under the name of liver-opal, derived from its colour.

MENIMAN, in *Geography*, a town of Asiatic Turkey, in Natolia, from which Smyrna draws its chief supply of fruits and provisions.

MENIN, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. This town consists of little more than one street, with one parish church, situated on the Lys; and yet it has been the subject of many contests and vicissitudes during various wars. The place contains 4911, and the canton 17,769 inhabitants, on a territory of 100 kiliometres, in seven communes. N. lat. 50° 48'. E. long. 3° 5'.

MENING, in *Botany*, a name given by the people of Guinea to a plant of the *resinous* or *palma Christi* kind, which they use in medicine: they dry and powder the leaves, and then give them to be snuffed up the nostrils, to cure all sorts of stuffings or stoppages in the head. Its leaves resemble those of the finch and ivy, and are hairy; whence Petiver has named it *ricinus Guineensis hæderæ quinquefolia Virginianæ facie foliis hirsutis*. It is not known to grow any where in America. Philos. Trans. N° 232.

MENINGE, in *Ancient Geography*, an island of Africa. Plutarch, in Mario, says that Marius landed on the island of Meninge, and that from thence he passed to Carthage. This island is called by Ptolemy Lothophagites, in which were two towns, *viz*. Gerrapolis and Meninge.

MENINGEA ARTERIA, in *Anatomy*, a branch of the internal maxillary artery distributed upon the dura mater. See ARTERY.

MENINGES, from μηνιγξ, *a membrane*; a term sometimes employed in speaking of the membranes of the brain.

MENINGOPHYLAX, from μηνιγξ, *a membrane*, and φυλασσω, *to guard*, an instrument in use amongst the ancient surgeons for protecting the dura mater and brain from injury, in their mode of trepanning. It was somewhat like the lenticular, only its blade was completely round, without any edge, and it ended, like this other instrument, in a lentiform cup.

MENINSKI, or MENIN, FRANCIS, in *Biography*, a considerable oriental scholar, was born at Lorraine in 1623. Of the early part of his life we have no account, but he studied at Rome, and being particularly attached to the acquisition of the Eastern languages, when about the age of thirty he accompanied the Polish ambassador to Constantinople, and there applied so assiduously to the study of the Turkish tongue, that in a very short time he was made first interpreter to the Polish embassy at the Porte; and afterwards

was

was raifed to the office of ambaffador plenipotentiary to that court. Hence he was naturalized in Poland, and added the termination *ſki* to the family name of *Menin*. In 1661 he accepted the poft of interpreter of the Oriental languages at the court of Vienna, and accompanied the imperial ambaffador to the Porte. In 1669 he vifited the holy fepulchre at Jerufalem, and was created a knight of that order. His fervices were fo much approved, that on his return to Vienna he was appointed one of the emperor's council of war, as well as firft interpreter. He died in 1698. As an author, the great work of Meninfki was his "Thefaurus Linguarum Orientalium," publifhed at Vienna in 1680, in four volumes folio. Of thefe the fourth was entirely deftroyed by the falling of a bomb upon the author's houfe during the fiege of Vienna by the Turks, which obliged him to recompofe it. The other volumes were greatly injured at the fame time, which rendered the work extremely fcarce and dear. A new edition of it with improvements was begun at Vienna in the year 1780. The Turkifh, Perfian, and Arabian grammars contained in the "Thefaurus," were republifhed in two volumes quarto, 1756.

MENIPEAN, *Satira* MENIPEA, a kind of fatire confifting of profe and verfe intermixed.

It is thus called from Menippus, a Cynic philofopher, who delighted in compofing fatirical letters, &c. In imitation of him, Varro alfo wrote fatires under the title of "Satiræ Menippæ;" whence this fort of compofition is alfo denominated *Varronian fatire*.

Among the moderns, there is a famous piece under this title, firft publifhed in 1594, againft the chiefs of the league, called alfo the "Catholicon" of Spain. It is efteemed a mafter-piece for the time.

MENISCIUM, in *Botany*, fo called by Schreber, the author of the genus, from μηνισκος, *a crefcent*, in allufion to the fhape of the fructification. Schreb. Gen. 757. Swartz. Syn. Fil. 19. Sprengel Crypt. 93. t. 3. f. 20. Cavan. Leccion. 548. Mart. Mill. Dict. v. 3. Lamarck Dict. v. 4. 93. Clafs and order, *Cryptogamia Filices*. Nat. Ord. *Filices*, Linn. Juff.

Gen. Ch. *Capfules* annulated, in fmall, fingle, curved lines, nearly parallel to each other, and fituated tranfverfely, in regular feries, betwixt the veins of the *frond*. *Involucrum* none.

Eff. Ch. Fructification in a feries of fmall, tranfverfe, crefcent-fhaped lines, between the veins of the frond. Involucrum none.

1. M. *triphyllum*. Swartz. n. 1. Sprengel as above.—Frond three-leaved. Native of China and the Eaft Indies. Sprengel reprefents the *frond* as about five inches long, fmooth, confifting of one large, terminal, oblong, pointed, entire *leaflet*, and a pair of much fmaller, oppofite, feffile ones, a little below it. Each of the leaflets is furnifhed with a midrib, and numerous tranfverfe, oblique, parallel veins, connected by fine, regular, decuffating lines of fructification.

2. M. *reticulatum*. Sw. n. 2. (Polypodium reticulatum; Linn. Sp. Pl. 1549. Afplenium forbifolium; Jacq. Coll. v. 2. 106. t. 3. f. 2. Filix latifolia non ramofa, nigris tuberculis pulverulenta; Plum. Amer. 6. t. 9. Lingua cervina, nigris tuberculis pulverulenta; Plum. Fil. 92. t. 110.)—Frond pinnate; leaflets undivided.—Native of the Weft Indies. We have it from St. Kitt's. Plumier found it very abundantly in afcending the mountain called *de la Calebaffe*, in Martinico. This is a very large and handfome *fern*, about four feet high; the *ftalks* fmooth and fhining, dark brown, or black. *Leaflets* numerous, about a fpan long, and above an inch wide, almoft feffile, alternate, broadeft near the bafe, tapering to a fharp narrow point; the margin flightly crenate, or wavy. The whole under-fide is covered with *fructification*, in curved *lines*, more anfwering to the form of a crefcent than thofe of the former fpecies. Sprengel cenfures Linnæus without reafon for making this fern a *Polypodium*; for the latter, having never feen a fpecimen in fructification, neceffarily trufted to Plumier, whofe figures, lefs faithful than ufual, as well as his definition, abundantly juftify Linnæus.

3. M. *proliferum*. Sw. n. 3. (Hemionitis prolifera; Retz. Obf. fafc. 6. 38.)—Frond pinnate; leaflets lanceolate, crenate, with axillary fmaller leaflets. Sent by Koenig from the Eaft Indies. It is defcribed as a large decumbent *fern*, with alternate, feffile, lanceolate, crenate *leaflets*, about half a foot long, abrupt at their bafe. From thefe are produced, at their origin, other axillary *fronds* or *branches*, a foot and half long, often in pairs, whofe *leaflets* are exactly like the former, but much fmaller, and the *ftalk* has a knot at the part whence they originate. *Fructification* in decuffating irregular *lines*, fo as fometimes to give the character of a *Polypodium*, fometimes of an *Acroftichum*.

4. M. *criftatum*. Lamarck Dict. v. 4. 94.—"Frond pinnate; leaflets nearly oppofite, lanceolate, pointed; the lower ones pinnatifid, with obtufe finely toothed fegments."—Native of Martinico. *Fronds* about a foot and a half high, or more, with numerous falcate *leaflets*, of a delicate texture, about four inches long, and near an inch broad. The margin is cut throughout into rounded lobes or fegments, finely toothed at their edge. *Fructification* copious, in curved lines.

Swartz enumerates this among his doubtful fpecies; we do not diftinctly fee for what reafon.

5. M. *ferratum*. Cavan. Leccion. 548.—"Frond pinnate; leaflets alternate, lanceolate, ferrated."—Native of the Havannah. *Fronds* above two feet high, fhining. *Leaflets* five inches long, the lower ones an inch broad; all fharp-pointed, finely toothed. *Fructification* in curved parallel *lines*.

This alfo is reckoned by Swartz among the fpecies which merit further inquiry; as well as a *Menifcium* from Cayenne, of which nothing is given but the generic character by Richard in the *Actes de la Société d'Hift. Nat. de Paris*, v. 1. 114.

Although *Menifcium* is, as yet, known to confift of but few fpecies, it has all the characters of a very natural genus, nearly refembling *Hemionitis* indeed in character, but diffimilar in habit.

MENISCUS, in *Optics*, a glafs or lens, concave on one fide, and convex on the other; fometimes alfo called *lunula*. See LENS, and OPTIC *Glafs*.

In a menifcus, if the diameter of the convexity be equal to that of the concavity, a ray, falling parallel to the axis, will continue parallel thereto after refraction.

Such a menifcus, therefore, will neither collect nor difperfe the rays; and is therefore of no ufe in dioptrics.

To find the focus of a menifcus, the rule is, as the difference of the femidiameters of the convexity and concavity is to the femidiameter of the convexity, fo is the diameter of the concavity to the diftance of the focus from the menifcus. Hence, if the femidiameter of the concavity be triple the femidiameter of the convexity, the diftance of the focus from the menifcus will be equal to the femidiameter; and therefore the menifcus will be equivalent to a lens equally convex on either fide.

Again, if the femidiameter of the concavity be double that of the convexity, the diftance of the focus will be equal

 to

to the diameter; and therefore the meniscus will be equivalent to a plano-convex lens.

If the semidiameter of the concavity be quintuple that of the convexity, the meniscus will be equivalent to a sphere. The semidiameter, therefore, of the convexity being given, that of the concavity required to remove the focus to any given distance from the meniscus, is easily found.

MENISPERMA, in *Botany*, the seventy-seventh natural order in Jussieu's system, the seventeenth of his thirteenth class, named from the principal genus belonging to it; see the next article. For the characters of the class, see GERANIA. The order is defined as follows:

Calyx of a definite number of leaves. *Petals* of a definite number, opposite to the calyx; with an equal number of scales, in some of the genera, at the inside of the petals and opposite to them. *Stamens* of a definite number, equal to that of the petals, and opposite to them. *Germens* several, with as many styles and stigmas. *Fruits* as many, either pulpy or capsular, kidney-shaped, each containing one seed, of their own shape; many of them however are frequently abortive, one only coming to perfection. *Embryo* flat, small, with thin lobes, situated at the top of the fleshy albumen, which is much more incurved than itself. *Stem* shrubby, mostly sarmentose. *Leaves* alternate, simple, without stipulas. *Flowers* axillary or terminal, often in aggregate spikes or clusters, each collection attended by a single bractea; they often become dioecious by imperfection of the respective organs of impregnation.

The genera enumerated by Jussieu are *Cissampelos; Menispermum; Leaba* of Forskall, perhaps not different from it; *Epibaterium* of Forster; and *Abuta* of Aublet.

The opposite situation, with respect to each other, of the calyx, petals, and stamens, brings this order near that of the *Berberides;* but the germen of the latter is simple, with many seeds, their albumen straight, surrounding the whole embryo, which is longer than in the *Menisperma*, and their anthers are differently formed, being very peculiar, and opening by revolute valves, in the *Berberides*. Their habits moreover are very unlike.

MENISPERMUM received its name, composed of μηνη, *the moon*, and σπερμα, *seed*, from Tournefort, in the Memoires de l'Acad. des Sciences for 1705; in allusion to the crescent-like form of the seed. Linn. Gen. 530. Schreb. 700. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 411. Juss. 285. Michaux Boreal-Amer. v. 2. 241. Lamarck Dict. v. 4. 94. Illustr. t. 824. Gærtn. t. 46. and t. 70. Class and order, *Dioecia Dodecandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Menisperma*, Juss.

Gen. Ch. Male, *Cal.* Perianth of two short linear leaves. *Cor.* Outer petals four, ovate, spreading, equal; inner eight, smaller, inversely heart-shaped, concave, four of them in an inner row and broader. *Stam.* Filaments 16, cylindrical, rather longer than the corolla; anthers terminal, very short, bluntly four-lobed.

Female, *Cal.* and *Cor.* as in the male. *Stam.* Filaments eight, like the male, but with pellucid abortive anthers. *Pist.* Germens two or three, superior, stalked, ovate, incurved, approaching each other; styles solitary, very short, recurved; stigmas cloven, obtuse. *Peric.* Berries two or three, roundish-kidney-shaped, of one cell. *Seeds* solitary, large, kidney-shaped.

Obs. By the accounts of authors, the number of the different parts of fructification either differs in different species, or varies in the same. The above characters are taken from *M. canadense*.

Ess. Ch. Male, Outer petals four, inner eight. Stamens sixteen.

Female. Petals as in the male. Eight imperfect stamens. Berries two or three, single-seeded.

A genus of twining, perennial, often shrubby, plants, altogether strangers to Europe, but found in North America, Arabia and Japan, as well as in the East and West Indies. The *roots* of some are large and solid, worthy of inquiry as to their medicinal powers. *Leaves* alternate, stalked, simple, generally undivided, entire, and more or less downy, of a heart-shaped or ovate figure, without *stipulas*. *Flowers* small, racemose, axillary, inconspicuous, of a green, whitish, yellowish, or lurid hue. *Berries* dark, the size of small peas, in some cases narcotic. The species are not very correctly understood, and it is probable many more exist than botanists have ascertained. The fourteenth edition of Syst. Veg. enumerates eleven. The volume of Willdenow which comprehends this genus is not yet come to our hands. We shall therefore only mention some of the most remarkable species.

M. *canadense*. Canadian Moon-seed. Linn. Sp. Pl. 1468. Mill. Illustr. t. 93. (Hedera monophylla, convolvuli foliis, virginiana; Pluk. Phyt. t. 36. f. 2)—Leaves peltate, heart-shaped, rounded and angular. Clusters compound, drooping.—Native of North America—"from Canada to Carolina." *Michaux*. *Stem* somewhat shrubby, twining contrary to the sun's course, (*Miller*,) round, smooth, leafy, slightly branched. *Leaves* on long stalks, generally broader than long, peltate a little way from the base, either simply cordate and undivided, or more or less deeply lobed, the lobes either rounded or angular; the upper side dark green, nearly smooth; under glaucous, a little hairy at the ribs and numerous veins. *Panicles* in pairs, shorter than the leaves, drooping. *Flowers* greenish-white. *Berries*, according to Clayton, black.—This plant is preserved in some botanic gardens, but has little beauty to recommend it to general favour.

M. *virginicum*. Virginian Moon-seed. Linn. Sp. Pl. 1468. (M. folio hederaceo; Dill. Elth. v. 2 223. t. 178. f. 219.) Upper leaves ovate, undivided; lower three-lobed and wavy. Clusters simple, solitary, erect.—Native of Virginia. Linnæus appears not to have known this species. The specimen in his herbarium, from whence the specific character was taken, is only the foregoing. Dillenius has well figured and described the real *virginicum*, as having *leaves* much resembling ivy, the upper ones being ovate and undivided; the lower lobed and angular. The latter especially are somewhat downy. None of them are peltate. The *flowers* are whitish, in upright, simple, much smaller clusters. *Berries* black. Michaux does not mention this in his *Flora*. It is said to be cultivated in the Cambridge garden, flowering in July.

M. *carolinum*. Carolina Moon-seed. Linn. Sp. Pl. 1468. Michaux Boreal-Amer. v. 2. 242.—Leaves heart-shaped, downy beneath. Clusters cymose.—Native of Carolina, *Linn.* also of Georgia and Florida. *Michaux*. This has the *leaves* heart-shaped, undivided, roughish above, soft and downy beneath. *Clusters* nearly as long as the leaves, cymose, hairy, of numerous small *flowers*. Michaux says the *berries* are red; otherwise we should have a suspicion that his plant was the *virginicum*.

M. *Cocculus*. Indian-berry Moon-seed. Linn. Sp. Pl. 1468. (Cocculæ officinarum; Bauh. Pin. 511. Cocci; Ger. em. 1548. Tuba baccifera; Rumph. Amb. v. 5. 35. t. 22.)—Leaves heart-shaped, pointed, somewhat downy beneath. Clusters compound, from the naked woody stem. Berries nearly globular. Native of Ceylon and Malabar. This has a very woody, branched and twisted *stem*, from whence the *flowers* proceed, in compound *clusters*. The

branches

Branches are leafy. *Leaves* large, a span long, heart-shaped, pointed; dark green above; downy beneath; on long twisted *footstalks*. *Berries* purplish-black, as big as a black currant; but they come to us dried, and of a much smaller size. They are used in India for catching fish, which they intoxicate if thrown into the water. Their use for this purpose is, we believe, prohibited in England; nor is it easy to account for the copious importation of these berries as an article of trade, unless they serve to adulterate fermented liquors, as is often reported. (See COCCULUS and CISSAMPELOS.) We apprehend that Poiret, quoted in the last article, has confounded two very distinct plants. We have from the East Indies, by the name of *Menispermum orbiculatum*, as well as from the Mauritius, specimens which answer exactly to his description of the female *Cissampelos Cocculus*; but their axillary simple *clusters*, and large heart-shaped *bracteas*, to say nothing of their rounder *leaves*, mark them as sufficiently distinct from the above shrub of Rumphius. Perhaps the berries of several Indian plants, of this family, may have the same intoxicating quality, and be used indiscriminately.

MENISPERMUM, in *Gardening*, contains plants of the hardy climbing kind, of which the species cultivated are, the Canadian moon-seed (M. canadense); the Virginian moon-seed (M. virginicum); and the Carolina moon-seed (M. carolinum.)

Method of Culture.—The two first sorts are easily propagated by laying down the branches in the autumn season, and when the layers have made good roots, in the following autumn they may be separated and planted out where they are to remain. As their branches are weak and slender, they require support; and when planted near trees thrive better than in an open situation.

And the third sort may be increased by parting the roots, and planting them out in the spring, a little before the plants begin to shoot, in warm situations where the soil is light, as in strong retentive land the roots are apt to rot. When planted close to a wall exposed to the south or west, their stalks may be fastened against the wall to prevent their trailing upon the ground; in which situations the plants frequently flower. They should have a little shelter in severe frost, in order to preserve their stalks.

All these plants afford ornament and variety in the shrubberies and other parts of pleasure grounds.

MENITZ, in *Geography*, a town of Moravia, in the circle of Brunn; nine miles S.S.E. of Brunn.

MENKIN, a town of Asiatic Turkey, in Natolia; 36 miles N.E. of Boli.

MENMEN, a town of Asiatic Turkey, in Natolia; 18 miles N.W. of Smyrna.

MENNO, in *Biography*. See the following article.

MENNONITES, in *Ecclesiastical History*, a sect in the United Provinces, in most respects the same with those in other places called Anabaptists.

They had their rise in 1536, when Menno Simon, a native of Friesland, who had been a Romish priest, and a notorious profligate, resigned his rank and office in the Romish church, and publicly embraced the communion of the Anabaptists.

Menno was born at Witmarsum, a village in the neighbourhood of Bolswert, in Friesland, in the year 1505, and died in 1561, in the duchy of Holstein, at the country seat of a certain nobleman, not far from the city of Oldesloe, who, moved with compassion by a view of the perils to which Menno was exposed, and the snares that were daily laid for his ruin, took him, with certain of his associates, into his protection, and gave him an asylum. The writings of Menno, which are almost all composed in the Dutch language, were published in folio, at Amsterdam, in the year 1651. About the year 1537, Menno was earnestly solicited by many of the sect with which he connected himself, to assume, among them, the rank and functions of a public teacher; and as he looked upon the persons who made this proposal, to be exempt from the fanatical phrenzy of their brethren at Munster (though, according to other accounts, they were originally of the same stamp, only rendered somewhat wiser by their sufferings), he yielded to their intreaties. From this period to the end of his life he travelled from one country to another, with his wife and children, exercising his ministry, under pressures and calamities of various kinds, that succeeded each other without interruption, and constantly exposed to the danger of falling a victim to the severity of the laws. East and West Friesland, together with the province of Groningen, were first visited by this zealous apostle of the Anabaptists; from thence he directed his course into Holland, Guelderland, Brabant, and Westphalia, continued it through the German provinces that lie on the coasts of the Baltic sea, and penetrated so far as Livonia. In all these places his ministerial labours were attended with remarkable success, and added to his sect a prodigious number of followers. Hence he is deservedly considered as the common chief of almost all the Anabaptists, and the parent of the sect that still subsists under that denomination. Menno was a man of genius, and directed by a very sound judgment; he possessed a natural and persuasive eloquence, and such a degree of learning as made him pass for an oracle in the estimation of the multitude. He appears, moreover, to have been a man of probity, of a meek and tractable spirit, gentle in his manners, pliable and obsequious in his commerce with persons of all ranks and characters, and extremely zealous in promoting practical religion and virtue, which he recommended by his example, as well as by his precepts. The plan of doctrine and discipline drawn up by Menno was of a much more mild and moderate nature than that of the furious and fanatical Anabaptists, whose tumultuous proceedings have been recited under that article, but somewhat more severe, though more clear and consistent than the doctrine of the wiser branches of that sect, who aimed at nothing more than the restoration of the Christian church to its primitive purity. Accordingly, he condemned the plan of ecclesiastical discipline, that was founded on the prospect of a new kingdom, to be miraculously established by Jesus Christ on the ruins of civil government and the destruction of human rulers, and which had been the fatal and pestilential source of such dreadful commotions, such execrable rebellions, and such enormous crimes. He declared, publicly, his dislike of that doctrine which pointed out the approach of a marvellous reformation in the church by the means of a new and extraordinary effusion of the Holy Spirit. He expressed his abhorrence of the licentious tenets which several of the Anabaptists had maintained, with respect to the lawfulness of polygamy and divorce, and, finally, considered as unworthy of toleration, those fanatics who were of opinion that the Holy Ghost continued to descend into the minds of many chosen believers, in as extraordinary a manner as he did at the first establishment of the Christian church, and that he testified this peculiar presence to several of the faithful, by miracles, predictions, dreams, and visions of various kinds. He retained, indeed, the doctrines commonly received among the Anabaptists, in relation to the baptism of infants, the millenium, or thousand years reign of Christ upon earth, the exclusion of magistrates from the Christian church, the abolition of war, and the prohibition of oaths enjoined by our

Saviour, and the vanity as well as the pernicious effects of human ſcience. But while Menno retained theſe doctrines in a general ſenſe, he explained and modified them in ſuch a manner, as made them reſemble the religious tenets that were univerſally received in the Proteſtant churches; and this rendered them agreeable to many, and made them appear inoffenſive even to numbers who had no inclination to embrace them. It however ſo happened, that the nature of the doctrines conſidered in themſelves, the eloquence of Menno, which ſet them off to ſuch advantage, and the circumſtances of the times, gave a high degree of credit to the religious ſyſtem of this famous teacher among the Anabaptiſts, ſo that it made a rapid progreſs in that ſect. And thus it was in conſequence of the miniſtry of Menno, that the different ſorts of Anabaptiſts agreed together in excluding from their communion the fanatics that diſhonoured it, and in renouncing all tenets that were detrimental to the authority of civil government; and, by an unexpected coalition, formed themſelves into one community.

Though the Mennonites uſually paſs for a ſect of Anabaptiſts, yet M. Herman Schyn, a Mennonite miniſter, who has publiſhed their hiſtory and apology, maintains, that they are not Anabaptiſts, either in principle or by origin. However, nothing can be more certain than this fact, *viz.* that the firſt Mennonite congregations were compoſed of the different ſorts of Anabaptiſts, of thoſe who had been always inoffenſive and upright, and of thoſe who, before their converſion by the miniſtry of Menno, had been ſeditious fanatics: beſides, it is alleged that the Mennonites do actually retain, at this day, ſome of thoſe opinions and doctrines, which led the ſeditious and turbulent Anabaptiſts of old to the commiſſion of ſo many and ſuch enormous crimes: ſuch particularly is the doctrine concerning the nature of Chriſt's kingdom, or of the church of the New Teſtament, though modified in ſuch a manner as to have loſt its noxious qualities, and to be no longer pernicious in its influence.

The Mennonites are ſubdivided into ſeveral ſects; whereof the two principal are the Flandrians, or Flemingians, and the Waterlandians. The opinions, ſays Moſheim, that are held in common by the Mennonites, ſeem to be all derived from this fundamental principle, that the kingdom which Chriſt eſtabliſhed upon earth is a viſible church or community, into which the holy and juſt alone are to be admitted, and which is conſequently exempt from all thoſe inſtitutions and rules of diſcipline, that have been invented by human wiſdom, for the correction and reformation of the wicked. This principle, indeed, was avowed by the ancient Mennonites, but it is now almoſt wholly renounced; nevertheleſs, from this ancient doctrine, many of the religious opinions, that diſtinguiſh the Mennonites from all other Chriſtian communities, ſeem to be derived: in conſequence of this doctrine, they admit none to the ſacrament of baptiſm, but perſons that are come to the full uſe of their reaſon; they neither admit civil rulers into their communion, nor allow any other members to perform the functions of magiſtracy; they deny the lawfulneſs of repelling force by force, and conſider war, in all its ſhapes, as unchriſtian and unjuſt: they entertain the utmoſt averſion to the execution of juſtice, and more eſpecially to capital puniſhments; and they alſo refuſe to confirm their teſtimony by an oath. The particular ſentiments that divided the more conſiderable ſocieties of the Mennonites are the following; the rigid Mennonites, called the Flemingians, maintain with various degrees of rigour, the opinions of their founder Menno, as to the human nature of Chriſt, alleging that it was produced in the womb of the Virgin, by the creating power of the Holy Ghoſt; the obligation that binds us to waſh the feet of ſtrangers, in conſequence of our Saviour's command; the neceſſity of excommunicating and avoiding, as one would do the plague, not only avowed ſinners, but alſo all thoſe who depart, even in ſome light inſtances pertaining to dreſs, &c. from the ſimplicity of their anceſtors; the contempt due to human learning, and other matters of leſs moment. However, this auſtere ſyſtem declines, and the rigid Mennonites are gradually approaching towards the opinions and diſcipline of the more moderate Waterlandians.

The firſt ſettlement of the Mennonites, in the United Provinces, was granted them by William, prince of Orange, towards the cloſe of the ſixteenth century; but it was not before the following century, that their liberty and tranquillity were fixed upon ſolid foundations, when, by a confeſſion of faith, publiſhed in the year 1626, they cleared themſelves from the imputation of thoſe pernicious and deteſtable errors that had been laid to their charge. In order to appeaſe their inteſtine diſcords, a conſiderable part of the Anabaptiſts of Flanders, Germany, and Frieſland, concluded their debates in a conference held at Amſterdam, in the year 1630, and entered into the bonds of fraternal communion, each reſerving to themſelves a liberty of retaining certain opinions. This aſſociation was renewed and confirmed by new reſolutions, in the year 1649; in conſequence of which the rigorous laws of Menno and his ſucceſſors were, in various reſpects, mitigated and corrected. Moſheim's Eccl. Hiſt.

MENOCHIO, Jacopo, in *Biography*, a learned Italian juriſt, was born at Pavia, where he was probably educated, and was elected, in 1555, to the profeſſorſhip of civil law in its univerſity. Five years afterwards he accepted an invitation from Emanuel Philibert, duke of Savoy, to the newly erected univerſity of Mondovi. In 1566, he removed to Padua, and became profeſſor there, firſt of common law, and afterwards of civil law. In 1589, he was recalled by the ſenate of Milan to Pavia, and was, at length, elected a ſenator of Milan, and preſident of the extraordinary magiſtracy. He died in the city in 1607. He was a voluminous writer on ſubjects connected with his profeſſion, ſome of which are ſtill referred to by lawyers, particularly his treatiſes "De conjecturis ultimum Voluntatum," and "De tacitis et ambiguis conventionibus." Theſe are held in high eſtimation, and their author was unqueſtionably reckoned the firſt doctor in civil and canon law of the age in which he lived.

Menochio, John Stephen, a learned Jeſuit, who flouriſhed in the former part of the ſeventeenth century, ſon of the preceding, was born at Pavia in 1576. At the age of ſeventeen he entered the ſociety of Jeſus, where he diſtinguiſhed himſelf by his induſtry and talents, and was, at the cloſe of his academical courſe, ſelected to fill the chair of profeſſor: he was afterwards raiſed to the moſt honourable poſts belonging to the ſociety, in the colleges and provinces of Italy. He died at Rome in 1656. His principal works are, 1. "Hieropoliticon, ſeu Inſtitutiones Politicæ è Sacris Scripturis depromptæ;" 2. "De Republica Hebræorum;" 3. "Inſtitutiones Œconomicæ ex Sacris Literis depromptæ;" 4. "Brevis Explicatio ſenſus Literalis totius Scripturæ." The beſt edition of the laſt mentioned work was edited by father Tournemine in 1719, in 2 vols. folio: it was accompanied with a number of valuable treatiſes and diſſertations on biblical ſubjects. This father wrote "A Hiſtory of Chriſt," and ſix volumes of "Diſſertations," chiefly intended to elucidate the holy ſcriptures. Moreri.

MENOLOGY, Menologium, from μην, *month*, and λογος, *diſcourſe*, in the Greek church, is much the ſame with *martyrology*, or *calendar*, in the Latin.

The

The Greek menologium is divided into the several months in the year; and contains an abridgment of the lives of the saints, with a bare commemoration of the names of such whose lives were never written. The Greeks have various menologies; and the Romans tax them with inserting divers heretics, in their menologies, as saints. Baillet treats of them at large.

MENORRHAGIA, in *Medicine*, an excessive discharge of the menses in women.

The flow of the menses is considered as excessive, when it recurs more frequently, when it continues longer, or when, during the ordinary continuance, it is more abundant, than is usual with the same person at other times, and more especially when it gives rise to a train of symptoms, indicative of a general diminution of the constitutional strength. But as most women are liable to some inequality with respect to the period, the duration, and the quantity of the catamenia; so it is only when these deviations are excessive, or permanent, so as to induce a manifest deterioration of the health, that they are to be deemed morbid. The affections of the other functions of the body, therefore, are considered by Dr. Cullen as the chief test of the excessive discharge in individuals respectively. When a larger flow than usual, he says, of the menses has been preceded by headache, giddiness, or dyspnœa, and has been ushered in by a cold stage, and is attended with much pain of the back and loins, with a frequent pulse, heat and thirst, it may then be considered as preternaturally large. (Cullen, First Lines, par. 971.) The symptoms which inordinate menstruation leaves behind, however, are the most decided proofs of its morbid influence. For after a repetition of the copious discharges, the patient exhibits many symptoms of debility: the face becomes pale, and, if the loss of blood have been profuse, of a remarkably sallow or yellowish-white complexion, which has been aptly termed exsanguine, or bloodless; the pulse is weak and small, and rather more frequent than natural; an unusual lassitude is felt, and great debility on attempting to use exercise; the breathing is hurried by slight exertions; and the back becomes painful from continuance in an erect posture, in consequence of the feebleness of the muscles which support it: towards evening, likewise, the feet are somewhat enlarged by œdematous swelling. Other marks of debility, too, often appear; especially loss of appetite, with pain of the stomach, flatulence, and other symptoms of indigestion; frequent tendency to syncope or fainting; palpitation of the heart; and a weakness of mind, which becomes liable to strong emotions from slight causes, particularly when suddenly applied. From the local debility, produced in the parts from which the excessive discharge proceeds, there is also frequently a mucous discharge, or leucorrhæa, succeeding the menorrhagia; and, in many cases, when the debility has been much augmented by a recurrence of the disorder, there is a regular alternation of the one and the other; the leucorrhæa always appearing on the cessation of the menorrhagia, and continuing until the latter again returns; or, in a word, becoming habitual. See LEUCORRHÆA.

We shall not here enter into any theoretical discussion of the nature of the menstrual hæmorrhagy. It will be sufficient to state, that it is generally of what is called the active kind, and that it is accompanied by some degree of febrile *nisus* throughout the circulating system. The menorrhagia has hence been considered as depending, either upon the preternatural increase of the hæmorrhagic effort of the vessels of the uterus, or upon a preternatural laxity of the extremities of the uterine arteries, the hæmorrhagic effort remaining as in the natural state. Cullen, loc. cit.

The *exciting causes* of menorrhagia may, therefore, be included under the following heads. 1st. Those which increase the plethoric state of the uterine vessels; such as a full nutritious diet, much strong liquor, and especially when taken to the length of frequent intoxication, or combined with a sedentary life. There is much less of menorrhagia among the females of the lower class, in the country, who use a moderate diet, and take regular exercise, than among the ladies of the higher class, who live high, and use little active exercise, and particularly among those who take wine freely, though not to excess. And when young women have been weakened by this hæmorrhage, their matron-friends have too often recourse to more wine, and fuller diet, to restore the strength. This is even done in the pregnant state, to prevent abortions, when the opposite system should be adopted, with a view of diminishing both local and general plethora. 2dly. All causes which determine the blood more copiously and forcibly into the uterine vessels, tend of course to bring on menorrhagia. Such are violent strainings of the whole body, from particular exertions of the muscular strength; violent shocks from falls; severe blows or contusions on the lower belly; violent passions of the mind; and violent exercise, especially in dancing. For in the last mentioned instance, the combination of the muscular exertion with the erect posture tends materially to direct the current of blood to the uterus: and hence the exercise of dancing has sometimes been found an effectual remedy for obstructed menstruation. 3dly. Whatever irritates particularly the vessels of the uterus, may induce menorrhagia; as excess in venery, or the exercise of it during the time of menstruation; a costive habit of body, giving occasion to violent straining at stool; cold applied to the feet. 4thly. Whatever may have forcibly overstrained the extremities of the uterine vessels, and left them consequently in a weakened and relaxed state: such as frequent abortions, and tedious difficult labours, which give rise to excessive discharge; likewise frequent pregnancy, without nursing, which often not only deranges the general health, but occasions such a derangement of the uterine system, as leads to the production of frequent abortion, terminating in the constant occurrence of menorrhagia and leucorrhæa in alternate succession. And, lastly, all causes inducing a general laxity of the habit, such as living much in hot chambers, drinking much of warm relaxing liquors, as tea and coffee; or, on the other hand, the inability of procuring more substantial diet, combined with watching, fatigue, anxiety of mind, and other causes of constitutional debility, which often give rise to the constant alternations of menorrhagia and leucorrhæa in women of the lower classes.

The *treatment* of menorrhagia must necessarily differ according to the different causes of the disease, and the different states of constitution under which it occurs. In all instances, however, it is of the first importance to avoid the immediate causes of the malady, where these are obvious, and can be shunned; for in this way the returns of the disease may be often entirely warded off, and the health be fully restored, without recourse to medicine.

When this has not been done, and a copious menstrual discharge has come on, it will require the same kind of treatment as other active hæmorrhagies; especially if the patient be of a moderately strong habit; namely, such means as tend to allay inordinate action of the blood-vessels. One of the most important of these means is the application of *cold*, or, more correctly speaking, the abstraction of the stimulus of heat. With this view the apartment should be kept cool, the bed clothes should be light, and the beds not too soft; cold drink should be taken, as freely as the former

former habits of the patient will allow; and even cold applications should be made, as near to the bleeding vessels as may be, by applying wet cloths to the pudendum and round the loins. At the same time it is extremely important for the patient to remain entirely at rest, and that in the horizontal posture; to avoid the quickened circulation, which exertion produces, and the influence of gravitation upon the unsupported vessels in the erect position. The diet should likewise be light and cooling, all stimulants being discarded; and the bowels should be kept open by gentle laxatives, that occasion little stimulus; such as the neutral salts, castor oil, manna, sulphur, &c. Or the lower bowels may be emptied by clysters, which, if used cold, will have the double effect of removing the irritation of fæces, and also of refrigerating the uterus, by the contiguity of these parts.

It now and then happens that menorrhagia occurs in robust women, and is accompanied with quickness and some hardness of the pulse, with severe pains in the back resembling those of parturition, and other febrile symptoms. In these cases it is sometimes advisable to diminish the general action of the vascular system by bleeding from the arm, such a practice, however, is not often necessary; for there are few cases, in which the refrigerating plan above mentioned, if pursued with attention and diligence, will not tend to moderate the discharge.

On the other hand, when the menorrhagia arises from an apparent relaxation of the vessels of the uterus, although the practice of depletion must not be adopted, yet all the sources of irritation must be shunned with equal care: for, under such circumstances, the general irritability, or susceptibility of excitement, is usually much increased, and less active stimuli produce a greater effect. The menorrhagia may be presumed to arise from such a relaxed state of the uterine vessels, from the general debility and laxity of the patient's habit, indicated by paleness of complexion, thin and flabby state of the muscular flesh, languor, and incapability of exertion; as well as from a knowledge of her previous state of indisposition, of her mode of life, and of the immediate exciting causes; and particularly from the circumstance, that, in the intervals of menstruation, she is subject to leucorrhæa. Quietness and the horizontal posture are still more requisite in this than in the former case. And as there is often much general irritation combined with this condition of the habit, small doses of an opiate may be employed, with considerable benefit, in moderating the discharge. In the case of a plethoric habit, however, opiates would tend to produce an aggravation of the complaint by their stimulus, and therefore must be employed with caution. Astringent medicines must be resorted to, in the case of menorrhagia from relaxation, such as alum, the sulphuric acid, and some of the preparations of iron. The astringent operation of these, however, when given internally, is not always very active: the chalybeates, especially the muriated tincture of iron, are, on the whole, the most efficacious. The astringents may be employed externally, that is, may be applied locally, as washes, with advantage. These astringent and tonic medicines, however, are administered perhaps with more decided benefit, in the intervals of menstruation, when they act rather as preventives, than as directly curative, by strengthening the whole system; and tend also to remove the leucorrhæa, which so often exists at those times. Cold bathing, chalybeate medicines, the metallic salts, cinchona and other bitters, together with exercise, especially in a carriage, are all serviceable in this view, during the intervals: and all the remedies recommended in the case of *Leucorrhæa*, (see that article,) although some of them are too stimulant to be exhibited during the occurrence of menorrhagia from debility, may be resorted to with benefit in the intervals. The patients should also use a good nutritious diet at the same time. And it may be added, that these remedies should be employed in menorrhagia, from whatever causes it may have been originally produced, if the disease have already induced a considerable degree of debility in the body. See Cullen, First Lines, par. 966—974. Hamilton on Female Complaints.

MENOSTEY, in *Geography*, a town of France, in the department of the Jura; four miles E.S.E. of Auxerre.

MENOTTE, a river of Cambodia, which runs into the gulf of Siam, N. lat. 11° 32'. E. long. 101° 30'.

MENOUGAT, a town of Asiatic Turkey, in Caramania; 20 miles N. of Alanieh.

MENOUX, St., a town of France, in the department of the Allier; seven miles W. of Moulins.

MENS, a town of France, in the department of the Isere, and chief place of a canton, in the district of Grenoble; 22 miles S. of Grenoble. The place contains 1883, and the canton 6516 inhabitants, on a territory of 242½ kiliometres, in ten communes.

MENSA *et Thoro*, *Divorce à*. See DIVORCE.

MENSÆ DOMESTICUS. See DOMESTICUS.

MENSALIA, MENSALS, such parsonages or livings as were formerly united to the tables of religious houses; and therefore by canonists called *mensal* benefices. See PARSONAGE and BENEFICE.

MENSARII, among the Romans, officers appointed to manage the public treasury, being sometimes three, and sometimes five in number.

MENSES, in *Physiology*, the monthly discharge from the uterus of the female subject. See GENERATION, under the head of *Physiology of the Female Organs*.

MENSES, *Suppression of*, in *Medicine*, or *Amenorrhæa* in the language of the nosologists, an interruption to the monthly discharge of women.

The interruption of the menstrual flux has been considered by physicians of two kinds; namely, the one, when the menses do not begin to flow at that period of life at which they usually appear, which has been called the *retention* (or *emansio mensium*); and the other, when, at a subsequent age, and after they have repeatedly taken place, they cease to return (independently of pregnancy) at their usual periods, which has been called the *suppression* of the menses (*suppressio mensium.*) See Cullen, Nosol. Method. Gen. cxxvi.

The first of these species of amenorrhæa, the *retention* of the menses, occurs of course in girls about the age of puberty, and is accompanied by a number of symptoms, indicative of great general languor of the whole habit; but it is most commonly marked especially by an extraordinary paleness of the complexion, often with some degree of yellow, or even of a greenish hue, from which the appellation of *green-sickness*, or technically *chlorosis*, has been given to the disease. It is true, indeed, that this appearance of the complexion is not always present, where there is a *retention* of the catamenia; but the general train of symptoms varies little, and the same plan of treatment is requisite under most of the varieties of the complaint; we shall, therefore, not repeat here the detail of the symptoms, or of the methods of cure, which we have described at great length under the article CHLOROSIS; which see.

The *suppression* of the menstrual flux, then, after it has been for some time established in its regular course, will be the subject of the few following observations. Every interruption

terruption of the difcharge, after it has once taken place, is not to be confidered as a cafe of fuppreffion; for, at its firft appearance, it is not always immediately eftablifhed with perfect regularity; and, therefore, an early interruption, efpecially when accompanied with the chlorotic fymptoms, may be deemed a cafe of *retention*. On the other hand, the difcharge may, at any period of life, be fuppreffed, when great general debility is induced by any caufe; and it commonly is thus interrupted, when any great chronic affection occurs, to enfeeble the powers of life. In fuch cafes, the fuppreffion is merely fymptomatic of thofe other affections, and does not itfelf become an object of medical treatment.

Moft of the inftances of idiopathic fuppreffion of the catamenia, in this country, are occafioned by, or at leaft are afcribed to, the action of *cold*, which is believed to produce a conftriction of the extreme veffels of the uterus, and thus to occafion a refiftance to the flow of blood through them. The influence of fear, and other depreffing paffions, is fuppofed to produce a fimilar effect. The fuppreffion feldom continues long, before it is accompanied by various fymptoms or diforders in different parts of the body; partly, perhaps, originating from an irregular determination of blood into other organs, in confequence of the plethoric condition occafioned by the fuppreffion of the cuftomary difcharge; and partly from the great general fympathy of the whole nervous fyftem, and of feveral organs in particular, with the condition of the uterus. From the firft of thefe caufes arife hæmorrhagies from various parts; as from the nofe, lungs, ftomach, &c. when the menfes are fuppreffed; as well as violent head-ache, acute pains in the cheft, &c.; and, at the fame time, from the nervous fympathy, various hyfterical and other nervous affections occur, often to a formidable extent. The convulfions of hyfteria, thus produced, are fometimes indeed more violent even than thofe of epilepfy; the colic pains, with coftivenefs, the *globus* in the throat, the violent flatulence, and other fymptoms of dyfpepfia, become often exceedingly tormenting.

Where the fuppreffion of the catamenia is obviously idiopathic, and productive of thefe fymptoms fecondarily, the principal indication of cure appears to be to remove the obftructed ftate of the circulation in the veffels of the uterus. In very ftrong and robuft habits, where, together with acute local pains, there is a great tendency to hæmorrhage, and a febrile or inflammatory difpofition alfo manifefts itfelf, even blood-letting may be reforted to with benefit in the commencement, to leffen the conftrictive action of the blood-veffels in general; and in fuch cafes, free purgation, together with the antiphlogiftic regimen, will likewife be requifite. In the great majority of inftances, however, the detraction of blood is unneceffary. A beneficial change is often produced upon the action of the uterine veffels, by local remedies; fuch efpecially as warm bathing, directed to the region of the uterus, by means of the femicupium, or of fomentation; the pediluvium; or emollient glyfters, which, from the contiguity of the large inteftine to the uterus, operate as an internal fomentation. In cafes where the fuppreffion is accompanied with great pain about the uterine region, but without fever, an anodyne glyfter, combining the effects of fomentation with thofe of an opiate, is fometimes extremely beneficial. Dr. Gregory ufed to mention, in his lectures at Edinburgh, that an anodyne enema, adminiftered at night, had fometimes brought back the catamenia before morning. Such applications, indeed, appear to be particularly efficacious, when there is an obvious attempt, as it were, in the conftitution to effect the difcharge. For, as Dr. Cullen has remarked, it commonly happens, in the cafes of fuppreffed catamenia, that though the difcharge does not actually appear at the ufual periods, there are often, at thofe periods, fome marks of an effort, having a tendency to produce the difcharge; it is, therefore, at thofe times efpecially, when the efforts of the fyftem concur, that we ought to refort to the remedies for curing a fuppreffion. Thefe concurring efforts are indicated by the exiftence of pains in the loins, with a fenfe of fulnefs in the region of the uterus, and other fymptoms which ufually indicate the approach, or accompany the flow of the catamenia in the healthy condition.

Thofe cafes in which the menfes flow after longer intervals, and in lefs quantity than ufual, approximate to the cafes of actual fuppreffion; and when they are attended with any of the diforders of the fyftem before alluded to, they are to be treated by the fame remedies as the cafes of entire fuppreffion. See Cullen, Firft Lines, par. 1007—1012.

The partial impediment to the flow of the menfes, which is accompanied with confiderable pain, (the *Amenorrhœa difficilis*, fpec. 3. of Cullen,) has been treated of under the more common appellation, *Dyfmenorrhœa*; which fee.

MENSGUT, in *Geography*, a town of Pruffia, in the province of Oberland; eight miles N. of Ortelfburg.

MENSHIÉ, or MEDCHIÉ, a town of Egypt; five miles N. of Girgé. The markets of this town are always well fupplied, becaufe the boats that are bound to the N. of Egypt, are accuftomed to put in here for a ftock of provifions. A conferve of wheat is fold here, which is highly valued in the country. It is compofed of corn fteeped in water for two days, then dried in the fun, and boiled to the thicknefs of a jelly: the pafte thus prepared is called "elnede" dew: it is fweet and nutritive. Menfhié is decorated with a large mofque. "Ptolemais Hermei," or Hermes, fo called becaufe the fymbolical deity Mercury was worfhipped there, a large and populous city, formerly ftood fouth of this fpot and near it. A few fcattered ruins, and a ftone-dike to confine the waters of the river, are the only remains which Menfhié preferves of its ancient fplendour. Sonnini.

MENSIS. See MONTH.

MENSIS *Chymicus*. See MENSTRUUM.

MENSIS *Vetitus*. See FENCE-*Month*.

MENSOORIA, in *Geography*, a caftle of the empire of Morocco, eight leagues from Rabat, in the province of Temfena, or Tremecen, built in the 12th century, by Jacob Almanfor, to afford an afylum to travellers during the night; the inhabitants of the furrounding country being a mifchievous and thieving people.

MENSORES, among the Romans, harbingers or officers, whofe bufinefs it was to go and fix upon lodgings for the emperor, when he took a journey to any of the provinces. Their office was alfo to mark out encampments, and affign every regiment its poft.

MENSORES alfo fignified land-furveyors, architects, or appraifers of houfes and public buildings. Thofe likewife who diftributed the provifions in the army, were called *menfores frumentarii*; and fervants who waited at table had the appellation of menfores.

MENSORES was likewife the title of officers among the Romans appointed to receive the provifions brought to the city by fea, and to fee them carefully laid up and preferved in public granaries, of which there were great numbers.

MENSTRUAL, or MENSTRUOUS, a term in *Medicine*, applied to the blood which flows from women in their ordinary monthly purgations. See MENSES.

MENSTRUAL *Epacts*. See EPACT.

MENSTRUAL *Longitude of the Moon*. See ARGUMENT.

MENSTRUATION, Excessive. See Menorrhagia.

Menstruation, *Painful.* See Dysmenorrhœa.

MENSTRUUM, Solvent, or Dissolvent, in *Chemiſtry*, any liquor that will diſſolve, that is, ſeparate the parts of hard bodies

The term takes its riſe from this, that ſome chemiſts pretend the complete diſſolution of a mixed body cannot be effected in leſs than forty days; which period they call a *philoſophical month.* See Solvent, and alſo Solution.

Menstruum, *Univerſal.* See Alkahest.

Menstruum, in *Pharmacy*, chiefly denotes a body that will extract the virtues of ingredients by infuſion, decoction, or the like. See Extract, Infusion, and Decoction.

MENSURATION is that branch of mathematics which is employed in aſcertaining the extenſion, ſolidities, and capacities of bodies; and in conſequence of its very extenſive application to the various purpoſes of life, it may be conſidered as one of the moſt uſeful and important of all the mathematical ſciences: in fact, menſuration, or geometry, which were anciently nearly ſynonimous terms, ſeem to have been the root whence all the other exact ſciences, with the exception of arithmetic, have derived their origin.

As ſoon as men began to form themſelves into ſociety, and direct their attention towards the cultivation of the earth, it became neceſſary to have ſome means of diſtinguiſhing one perſon's allotment from another, both as to poſition and quantity; as it did to enumerate the number of their flocks and herds; and hence, in all probability, the former gave riſe to the ſcience of menſuration, as the latter did to that of arithmetic; and though we may eaſily imagine that each of them remained for ages in a rude uncultivated ſtate, yet it is from this period that we muſt date their commencement; and therefore, to ſtate the preciſe time when they were diſcovered, or by whom they were firſt introduced, would be to trace out the origin of ſociety itſelf: on this head, therefore, we ſhall barely obſerve that in all probability they firſt aroſe from the humbleſt efforts of unaſſiſted genius, called forth by the great mother of invention, Neceſſity; and that they have ſince grown up by ſlow and imperceptible degrees, till they have at length acquired the dignity of the moſt perfect ſciences; as the acorn which is firſt accidentally ſown in a field, is in due courſe of time converted into the majeſtic oak.

But notwithſtanding we cannot attribute the invention of the ſcience of menſuration to any particular perſon, or nation, yet we may diſcover it in an infant ſtate, riſing as it were into a ſcientific form amongſt the ancient Egyptians; and hence the honour of the diſcovery has frequently been given to this people, and to the circumſtance of the overflowing of the Nile.

It is, however, to the Greeks that we muſt conſider ourſelves indebted for having firſt embodied the leading principles of this art into a regular ſyſtem. Euclid's Elements of Geometry were probably firſt wholly directed to this ſubject, and many of thoſe beautiful and elegant geometrical properties, which are ſo much and ſo juſtly admired, it is not unlikely aroſe out of ſimple inveſtigations directed ſolely to the theory and practical application of menſuration. Theſe collateral properties, when once diſcovered, ſoon gave riſe to others of a ſimilar kind, and thus geometry, which was firſt inſtituted for a particular and limited purpoſe, became itſelf an independent and important ſcience, which has perhaps done more towards harmonizing and expanding the human faculties, than all the other ſciences united.

But notwithſtanding the perfection which Euclid attained in geometry, the theory of menſuration was not in his time advanced beyond what related to right-lined figures, and this, ſo far as regards ſurfaces, might all be reduced to that of meaſuring a triangle; for as all right-lined figures may be reduced to a number of trilaterals, it was only neceſſary to know how to meaſure theſe, in order to find the ſurface of any other figure whatever bounded only by right lines. The menſuration of ſolid bodies, however, was of a more varied and complex nature, and gave this celebrated geometrician a greater ſcope for the exerciſe of his ſuperior talents, and ſtill confining himſelf to bodies bounded by right-lined plane ſuperficies, he was able to perform all that can be done even at this day. With regard to curvilineal figures, he attempted only the circle and the ſphere, and if he did not ſucceed in thoſe, he failed only where there was no poſſibility of ſucceſs; but the ratio that ſuch ſurfaces and ſolids have to each other he accurately determined.

After Euclid, Archimedes took up the theory of menſuration, and carried it to a much greater extent. He firſt found the area of a curvilinear ſpace, unleſs indeed we except the lunules of Hippocrates, which required no other aid than that of the geometrical elements. Archimedes found the area of the parabola to be two-thirds of its circumſcribing rectangle, which, with the exception above ſtated, was the firſt inſtance of the quadrature of a curvilinear ſpace. The conic ſections were at this time but lately introduced into geometry, and they did not fail to attract the particular attention of this celebrated mathematician, who diſcovered many of their very curious properties and analogies. He likewiſe determined the ratio of ſpheres, ſpheroids, and conoids, to their circumſcribing cylinders, and has left us his attempt at the quadrature of the circle. He demonſtrated that the area of a circle is equal to the area of a right-angled triangle, of which one of its ſides about the right angle is equal to the radius, and the other equal to the circumference, and thus reduced the quadrature of the circle to that of determining the ratio of the circumference to the diameter, a problem which has engaged the particular attention of the moſt celebrated mathematicians of all ages, but which remains at preſent, and in all probability ever will remain, the deſideratum of geometricians, and at the ſame time a convincing and humiliating proof of the limited powers of the human mind.

But notwithſtanding Archimedes failed in eſtabliſhing the real quadrature of the circle, it is to him we are indebted for the firſt approximation towards it. He found the ratio between the diameter of a circle, and the periphery of a circumſcribed polygon of 96 ſides, to be leſs than 7 to 22, or leſs than 1 to $3\frac{10}{70}$; but the ratio between the diameter, and periphery of an inſcribed polygon of the ſame number of ſides, he found to be greater than 1 to $3\frac{10}{71}$; whence, *à fortiori*, the diameter of a circle is to its circumference in a leſs ratio than 1 to $3\frac{1}{7}$, or leſs than 7 to 22. Having thus eſtabliſhed this approximate ratio between the circumference and diameter, that of the area of the circle to its circumſcribed ſquare, is found to be nearly as 11 to 14. Archimedes, however, makes the latter the leading propoſition. Theſe, it is true, are but rude approximations, compared with thoſe that have been ſince diſcovered, but conſidering the ſtate of ſcience at this period, particularly of arithmetic, we cannot but admire the genius and perſeverance of the man, who, notwithſtanding the difficulties that were oppoſed to him, ſucceeded in deducing this reſult, which may be conſidered as having led the way to the other more accurate approximations which followed, moſt of which, till the invention of fluxions, were obtained upon ſimilar principles to thoſe employed by this eminent geometrician.

Archimedes alſo determined the relation between the circle and ellipſe, as well as that of their ſimilar parts; beſides which figures he has left us a treatise on the spiral, a description of which will be given under that article. See SPIRAL.

Some advances were successively made in geometry and mensuration, though but little novelty was introduced into the mode of investigation till the time of Cavalerius. Till his time the regular figures circumscribed about the circle, as well as those inscribed, were always considered as being limited both as to the number of their sides, and the length of each. He first introduced the idea of a circle being a polygon of an infinite number of sides, each of which was of course indefinitely small; solids were supposed to be made up of an infinite number of sections indefinitely thin, &c. This was called the doctrine of indivisibles, which was very general in its application to a variety of difficult problems, and by means of it many new and interesting properties were discovered; but it unfortunately wanted that distinguishing characteristic which places geometry so pre-eminent amongst the other exact sciences. In pure elementary geometry we proceed from step to step, with such order and logical precision, that not the slightest doubt can rest upon the mind with regard to any result deduced from those principles; but in the new method of considering the subject, the greatest possible care was necessary in order to avoid error, and frequently this was not sufficient to guard against erroneous conclusions. But the facility and generality which it possessed, when compared with any other method then discovered, led many eminent mathematicians to adopt its principles, and of these Huygens, Dr. Wallis, and James Gregory, were the most conspicuous, being all very fortunate in their application of the theory of indivisibles. Huygens, in particular, must always be admired for his solid, accurate, and masterly performances in this branch of geometry. The theory of indivisibles was however disapproved of by many mathematicians, and particularly by Newton, who, amongst his numerous and brilliant discoveries, has given us that of the method of fluxions, the excellency and generality of which immediately superseded that of indivisibles, and revived some hopes of squaring the circle, and accordingly its quadrature was again attempted with the greatest eagerness. The quadrature of a space and the rectification of a curve, was now reduced to that of finding the fluent of a given fluxion; but still the problem was found to be incapable of a general solution in finite terms. The fluxion of every fluent was found to be always assignable, but the converse proposition, *viz.* of finding the fluent of a given fluxion, could only be effected in particular cases, and amongst these exceptions, to the great disappointment and regret of geometricians, was included the case of the circle, with regard to all the forms of fluxions under which it could be obtained.

At length all hopes of accurately squaring the circle, and some other curves being abandoned, mathematicians began to apply themselves to finding the most convenient series for approximating towards their true lengths and quadratures; and the theory of mensuration now began to make rapid progress towards perfection. Many of the rules, however, were given in the Transactions of learned societies, or in separate and detached works, till at length Dr. Hutton formed them into a complete treatise, entitled "A Treatise on Mensuration," in which the several rules are all demonstrated, and some new ones introduced. Mr. Bonnycastle also published a very complete work on this subject, entitled "An Introduction to Mensuration." These may be considered as standard works, and the only ones of importance in our language, though there are others on the same subject, as Hawney's and Robertson's, the latter of which only requires the demonstrations of the several rules, which are omitted, in order to render it also a very useful and valuable performance.

To the above slight sketch of the history and progress of this science, we shall annex a synopsis of the principal rules, drawn from the works above mentioned, which will be found very useful as a reference in a variety of cases.

SYNOPSIS OF THE PRINCIPAL RULES OF MENSURATION.

TRIANGLES.

Let a, b, c represent the three sides of the triangle, A, B, C the angles opposite to those sides respectively; p the perpendicular falling upon the base b; then,

1. The area $= \frac{1}{2} p\, b$
2. —— $= \frac{1}{2} a\, b$. sin. C $= \frac{1}{2} a\, c$ sin. B $= \frac{1}{2} b\, c$ sin. A.

Make $a + b + c = s$; then,

3. The area $= \sqrt{\left\{ \frac{1}{2} s \left(\frac{1}{2} s - a\right) \left(\frac{1}{2} s - b\right) \left(\frac{1}{2} s - c\right) \right\}}$
4. Log. area $= \frac{1}{2} \left\{ \text{log. } \frac{1}{2} s + \text{log. } \left(\frac{1}{2} s - a\right) + \text{log. } \left(\frac{1}{2} s - b\right) + \text{log. } \left(\frac{1}{2} s - c\right) \right\}$.

TRAPEZIUMS.

Let a, b, c, d, represent the four sides, a and c, b and d, being those which are opposite to each other, δ and δ' the two diagonals, M the angle formed by their intersection, also p, p', the perpendiculars falling from two opposite angles on the diagonal δ; then,

1. The area $= \frac{1}{2} \delta\, (p + p')$
2. —— $= \frac{1}{2} \delta\, \delta'$. sin. M
3. The area $= \left\{ (a^2 + c^2) \backsim (b^2 + d^2) \right\}$ tan. M.

If the trapezium be inscribable in a circle,

4. The area $= \sqrt{\left\{ (s - a)\, (s - b)\, (s - c)\, (s - d) \right\}}$
5. —— $= (a\, b + c\, d)$ sin. N.

where N is the angle contained by a and b, or by c and d.

If a and c, or b and d, be parallel, and p their perpendicular distance, then,

6. The area $= \frac{1}{2} p\, (c + a)$, or $\frac{1}{2} p\, (b + d)$.

REGULAR POLYGONS.

Let s represent one of the equal sides, n the number of sides, p the perpendicular falling from the centre of the polygons upon one of the sides; then,

1. The area $= \frac{1}{2} p\, s\, n$
2. —— $= n\, p^2$ tan. $\frac{360^\circ}{2\, n}$
3. —— $= \frac{1}{4}\, n\, s^2$ cotan. $\frac{360^\circ}{2\, n}$

This last general formula resolves itself into the following particular ones, *viz.*

		Sides.			
4.	Trigon	3	Area	$s^2 \times$	0·4330127
5.	Tetragon	4	——	$s^2 \times$	1·0000000
6.	Pentagon	5	——	$s^2 \times$	1·7204774
7.	Hexagon	6	——	$s^2 \times$	2·5980762
8.	Heptagon	7	——	$s^2 \times$	3·6339124
9.	Octagon	8	——	$s^2 \times$	4·8284271
10.	Nonagon	9	——	$s^2 \times$	6·1818242
11.	Decagon	10	——	$s^2 \times$	7·6942088
12.	Undecagon	11	——	$s^2 \times$	9·3656399
13.	Dodecagon	12	——	$s^2 \times$	11·1961524

Circle.

Let r reprefent the radius, d the diameter, c the circumference, and a the area; then,

1. The area $= \frac{1}{4} c\, d$
2. —— $= d^2 \times \cdot 7854$
3. —— $= c^2 \times \cdot 07958$
4. The circumference $= d \times 3\cdot 14159$

If we make $3\cdot 14159 = p$, we have the following relation of the above quantities; *viz.*

1. —— $d = \frac{c}{p} = \frac{4a}{c} = 2\sqrt{\frac{a}{p}}$

2. —— $c = p\, d = \frac{4a}{d} = 2\sqrt{p\, a}$

3. —— $a = \frac{p\, d^2}{4} = \frac{c^2}{4p} = \frac{d\, c}{4}$

4. —— $p = \frac{c}{d} = \frac{4a}{d^2} = \frac{c^2}{4a}$

Circular Arcs.

The former notation remaining; let s reprefent the fine, and v the verfed fine of the half arc; alfo let m reprefent the meafure of the arc in degrees, minutes, &c. then,

1. The arc $= r\, m \times \cdot 0174533$.

2. The arc $= \begin{cases} 2\sqrt{d v} \times \left\{ 1 + \frac{v}{2 \cdot 3 d} + \frac{3 v^2}{2 \cdot 4 \cdot 5 \cdot d^2} + \frac{3 \cdot 5 v^3}{2 \cdot 4\; 6 \cdot 7 d} + \text{\&c.} \right\} \text{ or,} \\ 2 d \sqrt{q} + \frac{q}{2 \cdot 3} A + \frac{3^2 q}{4 \cdot 5} B + \frac{5^2 q}{6 \cdot 7} C + \frac{7^2 q}{8 \cdot 9} D \end{cases}$

where $q = \frac{v}{d}$; and A, B, C, &c are the 1ft, 2d, 3d, &c. terms.

3. The arc $= \begin{cases} 2 s \times \left\{ 1 + \frac{s^2}{3 \cdot 3 r^2} + \frac{3 s^4}{5 \cdot 2 \cdot 4 r^4} + \frac{3 \cdot 5 s^6}{7 \cdot 2 \cdot 4 r^6}, \text{\&c.} \right\} \text{ or,} \\ 2 s + \frac{q}{2 \cdot 3} A + \frac{3^2 q}{4 \cdot 5} B + \frac{5^2 q}{6 \cdot 7} C + \frac{7^2 q}{8 \cdot 9} D, \text{\&c.} \end{cases}$

where $q = \frac{s^2}{r^2}$; and A, B, C, D, &c. the preceding terms.

To which may be added the following approximations:

4. The arc $= 2 d \sqrt{\frac{3 v}{3 d - v}}$ nearly.

5. —— $= \frac{2}{9} \times \left\{ 5 d \sqrt{\frac{5 v}{5 d - 3 v}} + 4 \sqrt{d v} \right\}$ nearly.

6. —— $= \frac{8 c' - C'}{3}$ nearly.

where C′ is the chord of the whole arc, and c' the chord of half the arc.

Circular Sectors.

Let l reprefent the length of the arc of the fector, and m its meafure in degrees, minutes, &c.; then,

1. Area of fector $= \frac{1}{2} r\, l$
2. —— $= \cdot 7854\, d^2 \times \frac{m}{360}$

Circular Segments.

If A′ reprefent the area of the circular fector, and C′ the chord of the arc; then,

1. Area of fegment $= A' - \frac{1}{2} C' (r - v)$.

2. Area $= \begin{cases} 2 v \sqrt{d v} \times \left\{ \frac{2}{3} - \frac{v}{5 d} - \frac{v^2}{28 d^2} - \frac{v^3}{72 d^3} - \text{\&c.} \right\} \text{ or,} \\ 2 \sqrt{d v} \times \left\{ \frac{2}{3} - \frac{3 v}{5 \cdot 2 d} A - \frac{5 v}{7 \cdot 4 d} B - \frac{7 \cdot 3 v}{9 \cdot 6 d} C - \frac{9 \cdot 5 v}{11 \cdot 8 d} D \right\} \end{cases}$

A, B, C, &c. being the preceding terms.

3. Area $= \frac{1}{3} v \sqrt{v V} + \frac{5}{5 V} A - \frac{1}{7 V} B + \frac{3}{9 V} C - \frac{5}{11 V} D$, &c. where $V = (d \quad v)$.

4. Area $= 2 r c'' - \frac{1}{2 \cdot 3} q^2 A - \frac{1 \cdot 3}{4 \cdot 5} q^2 B - \frac{3 \cdot 5}{6 \cdot 7} q^2 C$, &c. where c'' reprefents the cofine of half the arc, and $q = \frac{c''}{r}$, A, B, C, &c. being the preceding terms.

To which may be added the following approximations, *viz.*

5. Area $= \frac{4}{5} \left\{ \sqrt{(d v - v^2)} + \frac{2}{3} \sqrt{d v} \right\}$ nearly.
6. Area $= \frac{4}{7} v (d v - \frac{3}{5} v^2)$ nearly.

If C′ be made to reprefent the chord of the whole arc, and c the chord of half the arc, then

7. Area $= \frac{4}{10} v (C' + \frac{4}{3} c)$ nearly.
8. Area $= \frac{4}{3} v \sqrt{(\frac{1}{4} C'^2 + \frac{2}{5} v)}$ nearly.
9. Area $= d^2 \times$ by tabular number anfwering to $\frac{v}{d}$, in the table of circular fegments.

Note.—The area of circular zones will be found by finding the difference of the two fegments: and the area of circular rings, by finding the difference of the areas of the two circles.

Or

Or by making D and d the diameters, then

10. Area of the ring $= (D + d)(D - d) \times \cdot 7854$.

ELLIPSIS.

Let t represent the semi-transverse axis, c the semi-conjugate, x any abscissa, y the corresponding ordinate, and p the parameter; then will these quantities have the following relations, *viz.*

1. Ordinate $(y) = \frac{c}{t} \sqrt{(2xt - x^2)}$

2. Abscissa $(x) = t \pm \frac{t}{c} \sqrt{(c^2 - y^2)}$

3. Conjugate $(c) = \frac{ty}{\sqrt{(2tx - x^2)}}$

4. Transverse $(t) = \frac{cx}{y^2} \times \left\{ c \mp \sqrt{(c^2 - y^2)} \right\}$

5. Parameter $(p) = \frac{c^2}{t}$.

The same formulæ obtain for any pair of conjugate diameters.

Make $1 - \frac{c^2}{t^2} = m$; then,

1. Elliptic circum. $= C \times \left\{ 1 + \frac{m}{2^2} - \frac{3m^2}{2^2 \cdot 4^2} - \frac{3^2 \cdot 5 m^3}{2^2 \cdot 4^2 \cdot 6^2} - \frac{3^2 \cdot 5^2 \cdot 7 m^4}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2}, \text{ \&c.} \right\}$ where C is the circumference of the circumscribing circle.

2. Elliptic circum. $= (t + c) \times 3\cdot1416$ nearly.

3. —— $= 3\cdot1416 \times \sqrt{2(t^2 + c^2)}$ nearer.

4. —— $= \frac{1}{2} \left\{ 3\sqrt{2(t^2 + c^2)} - \frac{6t + p}{4} \right\} \times 3\cdot1416$ still nearer.

5. Elliptic circum. $= \frac{1}{2} \left\{ 5\sqrt{2(t^2 + c^2)} - \frac{35t + 7p}{8} + \frac{pc^2}{16t^2} \right\} \times 3\cdot1416$.

6. Elliptic circum. $= \frac{1}{2} \left\{ t + c + \sqrt{2(t^2 + c^2)} \right\} \times 3\cdot1416$.

7. Elliptic area $= 3\cdot14159 \times tc$.

8. —— $= 3\cdot14159 \times tc \times$ sin. angle of intersection, in which last expression t and c are any pair of semi-conjugate diameters.

ELLIPTIC ARCS.

Let t represent still the semi-transverse, c the semi-conjugate, and z the distance of the ordinate from the centre; then the arc bounded by the ordinate, and the parallel axis, will be

1. Elliptic arc $= z \left\{ 1 + \frac{c^2}{6t^4} z^2 + \frac{4t^2c^2 - c^4}{40t^8} z^4 + \frac{8t^4c^2 - 4t^2c^4 + c^6}{112t^{12}} z^6, \text{ \&c.} \right\}$

Make $\frac{t^2 - c^2}{t^2} = q$; then,

2. Elliptic arc $= z \sqrt{\frac{t^2 - \frac{1}{3}qz^2}{t^2 - \frac{1}{3}z^2}}$ nearly.

3. —— $= \frac{1}{5} \left\{ qz \sqrt{\frac{t^2 - \frac{1}{3}qz^2}{t^2 - \frac{1}{3}z^n}} - \left(1 + \frac{c^2z^2}{6t^4}\right) 4z \right\}$

4. Elliptic arc $= \frac{15pC + (19C - 21p)y}{15pC + (9C - 21p)y} \times x$ nearly, C being the whole axe, where the arc begins; and p, x, and y the corresponding parameter, abscissa, and ordinate.

ELLIPTIC SEGMENTS.

Find the area of the circular segment described on that axe to which the base of the segment is perpendicular, and call it A; then,

1. As this axe : the other axe :: A : the elliptic segment, make the height of the segment $= h$, and vertical axe of the ellipse $= v$, also put $\frac{h}{v} = q$; then,

2. Elliptic seg. $= tc \times$ tabular number answering to y in a table of circular segments.

PARABOLA.

Make any abscissa $= x$, ordinate $= y$, parameter $= p$, and area $= a$; then will these quantities have the following relations, *viz.*

1. Parameter $(p) = \frac{y^2}{x}$

2. Abscissa $(x) = \frac{y^2}{p}$

3. Ordinate $(y) = \sqrt{px}$

4. Area contained between x, y, and the curve $\Big\}$ $(a) = \frac{2}{3} xy$.

PARABOLIC ARCS.

Make $\frac{2y}{p} = q$, and $\sqrt{(1 + q^2)} = s$; then,

1. Parabolic arc $= \frac{1}{2} p \left\{ qs + \text{hyp. log. } (q + s) \right\}$

2. Parabolic arc $= \begin{cases} 2y \left(1 + \frac{q^2}{2 \cdot 3} - \frac{q^4}{2 \cdot 4 \cdot 5} + \frac{3q^6}{2 \cdot 4 \cdot 6 \cdot 7} - \frac{3 \cdot 5 q^8}{2 \cdot 4 \cdot 6 \cdot 8 \cdot 9}, \text{ \&c.} \right\} \\ 2y \left(1 + \frac{q^2}{2 \cdot 3} A - \frac{1 \cdot 3 q^2}{4 \cdot 5} B + \frac{3 \cdot 5 q^2}{6 \cdot 7} C - \frac{5 \cdot 7 q^2}{8 \cdot 9} D, \text{ \&c.} \right\} \end{cases}$

where A, B, C, &c. represent the preceding terms. To which may be added the following approximations:

3. Parabolic arc $= 2\sqrt{(y^2 + \frac{4}{3}x^2)}$ nearly.

4. —— $= \frac{2}{3} \left\{ \sqrt{(y^2 + \frac{4}{3}x^2)} - \frac{y^2 + \frac{2}{3}x^2}{\frac{1}{4}y} \right\}$ nearly.

PARABOLIC FRUSTUM, OF ZONE.

Let D and d represent the two ends, and a the perpendicular distance between them; then,

1. Area of zone $= \frac{2}{3} a \times \frac{D^3 - d^3}{D^2 - d^2}$

When $d = 0$, the area becomes $\frac{2}{3} aD$.

HYPERBOLA.

Let $t =$ the semi-transverse diameter, $c =$ the semi-conjugate, x any abscissa, and y its corresponding ordinate; then will these quantities have the following relations, *viz.*

1. Ordinate $(y) = \frac{c}{t} \sqrt{(2tx + x^2)}$

2. Abscissa

2. Abſciſs - $(x) = t \pm \frac{t}{2c}\sqrt{(c^2+y^2)}$

3. Conjugate $(c) = \frac{ty}{\sqrt{(2tx+x^2)}}$

4. Diameter - $(t) = \frac{cx}{y}\left\{\sqrt{(c^2+y^2)} \pm c\right\}$

Hyperbolic Arcs.

Let t and c be any ſemi-diameter and its conjugate as before; and y the ordinate which limits the arc to be meaſured from the vertex; then,

Making $\frac{t^2+c^2}{c^4} = q$, and hyp. log. $\frac{y+\sqrt{(c^2+y^2)}}{c} = \mathrm{A}$.

Alſo, $\frac{1}{2}\left\{y\sqrt{(c^2+y^2)} - c^2\mathrm{A}\right\} = \mathrm{B}.$

$\frac{1}{4}\left\{y^3\sqrt{(c^2+y^2)} - 3c^2\mathrm{B}\right\} = \mathrm{C}.$

$\frac{1}{6}\left\{y^5\sqrt{(c^2+y^2)} - 5c^2\mathrm{C}\right\} = \mathrm{D}.$

&c. &c. &c.

The length of the arc contained between the vertex and ordinate will be,

$$1.\ \text{Arc} = c \times \left\{\mathrm{A} + \frac{q}{2}\mathrm{B} - \frac{q^2}{2 \cdot 4}\mathrm{C} + \frac{3q^3}{2\cdot4\cdot6}\mathrm{D} - \frac{3\cdot5q^4}{2\cdot4\cdot6\cdot8}\mathrm{E},\ \&c.\right\}$$

$$2\ \text{Arc} = y \times \left\{\begin{array}{l} 1 + \frac{t^2y^2}{6c^4} - \frac{(t^4+4t^2c^2)y^4}{40c^8} + \frac{(t^6+4t^4c^2+8t^2c^4)y^6}{112c^{12}} \\ - \frac{(5t^8+24t^6c^2+48t^4c^4+64t^2c^6)y^8}{1152c^{16}},\ \&c. \end{array}\right.$$

$$3.\ \text{Arc} = y \left\{\begin{array}{l} 1 + \frac{t^2y^2}{6c^4}\mathrm{A} - \frac{t^2+4c^2}{c^4}\cdot\frac{3y^2}{20}\mathrm{B} + \frac{t^4+4t^2c^2+8c^4}{t^2+4c^2}\cdot\frac{5y^2}{14c^4}\mathrm{C} \\ - \frac{5t^6+24t^4c^2+48t^2c^4+64c^6}{t^4+4t^2c^2+8c^4}\cdot\frac{7y^2}{72c^4}\mathrm{D}\ \&c. \end{array}\right.$$

To which may be added the following approximation:

$$4.\ \text{Arc} = \frac{120c^2t + (19t^2+21c^2)4x}{120c^2t + (9t^2+21c^2)4x} + y,\ \text{nearly.}$$

Hyperbolic Segments.

Let t and c ſtill repreſent the ſemi-diameter and its conjugate, x an abſciſs, $2y$ the double ordinate, which cuts off the ſegment, and z its diſtance from the centre; then,

1. Hyp. area $= zy - tc \times$ hyp. log. of $\frac{ty+cz}{tc}$.

Making $\frac{x}{2t+x} = q$, we have

2. Hyp. area $= 2xy\left\{\frac{1}{3} - \frac{q}{1\cdot3\cdot5} - \frac{q^2}{3\cdot5\cdot7} - \frac{q^3}{5\cdot7\cdot9} - \&c.\right\}$

3. Hyp. area $= 2xy\left\{\frac{1}{3} - \frac{1}{5}\mathrm{A}q - \frac{1}{7}\mathrm{B}q - \frac{1}{9}\mathrm{C}q - \&c\right\}$

where A, B, C, &c. repreſent the preceding terms. To which may be added the following approximations, *viz.*

4. Hyp. area $= \frac{4cx}{15t}\left\{4\sqrt{(2tx+\frac{3}{4}x^2)} + \sqrt{2tx}\right\}$ nearly.

5. Hyp. area $= \frac{4cx}{75t}\left\{21\sqrt{(2tx+\frac{5}{7}x^2)} + 4\sqrt{2tx}\right\}$ nearly.

Hyperbolic Frustum, or Zone.

The ſame notation remaining as above, let z be the diſtance of a ſecond double ordinate $2\mathrm{Y}$; then,

1. The area of zone contained between $2y$ and $2\mathrm{Y}$ - $= \left\{\mathrm{ZY} - zy - tc \times \text{hyp. log.}\ \frac{t\mathrm{Y}+c\mathrm{Z}}{ty+cz}\right.$.

Prisms and Cylinders.

Let p repreſent the perimeter of the baſe, a its area, and h the height or perpendicular altitude; then,

1. Surface $= ph + 2a$
2. Solidity $= ah.$

Pyramids and Cones.

Let p, a, and h, repreſent, as above, the perimeter, area and altitude; then,

1. Surface $= \frac{1}{2}ph + a$
2. Solidity $= \frac{1}{3}ah.$

The latter rule obtains alſo in oblique cones and pyramids.

Frustums of Cones and Pyramids.

Let A and a repreſent the areas of the two ends, P and p their perimeters, and h the altitude of the body; then,

1. Surface $= \frac{1}{2}h(\mathrm{P}+p) + (\mathrm{A}+a)$
2. Solidity $= \frac{1}{3}h(\mathrm{A}+a) + \frac{1}{3}h(\sqrt{\mathrm{A}a}).$

If the ends are circles, or regular polygons, by putting D and d for the diameters, and C and c for the circumferences in the former caſe; alſo S and s for the ſides of the polygon in the latter, and T for the tabular number anſwering to any particular polygon; then,

4. Solidity of fruſt. cone $= \frac{1}{3}h(\mathrm{D}^2 + \mathrm{D}d + d^2)\ {\cdot}7854.$
5. —— fruſt. cone $= \frac{1}{3}h(\mathrm{C}^2 + \mathrm{C}c + c^2)\ {\cdot}07958.$
6. —— fruſt. pyra. $= \frac{1}{3}h(\mathrm{S}^2 + \mathrm{S}s + s^2)\ \mathrm{T}.$

Prismoid.

Let A and a repreſent the areas of the two ends, a the area

area of the middle section, and l the length of the solid; then,

1. Solidity $= \frac{1}{6} l (A + 4 a + a)$.

Wedge.

Make L the length of the base, l the length of the edge, b the breadth of the base, and h the height of the wedge; then,

1. Solidity $= \frac{1}{6} b h (2 L + l)$.

Cylindric Ungula.

When the plane passes through the base of the cylinder.

Make the altitude $=$ H, the base $= b$, $\frac{1}{2}$ arc of base $= a$, the sine, cosine, and versed sine of $\frac{1}{2}$ arc $= s$, c, and v, and diameter of cylindric base $= d$; then,

1. Curve surf. ungula $= \dfrac{(d s - a c)\,H}{v}$

2. Solidity ungula $= \dfrac{(\frac{2}{3} s^3 - b c)\,H}{v}$.

When the cutting plane does not pass through the base.

Put, in addition to the above notation, h for the least height of the ungula, H still representing the greater height; then,

1. Curve surface $= \frac{1}{2} (H + h) \times 3\cdot1416\, d$
2. Solidity $= \frac{1}{2} (H + h) \times \cdot7854\, d^2$
3. ——— $= \frac{1}{2} (H + h) \times \cdot07958\, c^2$

where c is the circumference of the cylinder.

Conic Ungula.

When the cutting plane passes through the opposite ends of the frustum.

Make the diameter of the greater end $=$ D, of the less end $= d$, and altitude $= h$; then,

1. Solidity gt. hoof $= \dfrac{D^2 - d\sqrt{Dd}}{D - d} \times \cdot2618\, D\, h$

2. ——— lt. hoof $= \dfrac{D\sqrt{Dd} - d^2}{D - d} \times \cdot2618\, D\, h$

3. Differ. of hoofs $= \dfrac{(D - d)^2}{D - d} \times \cdot2618\, h$.

Sphere, or Globe.

Let d represent the diameter, c the circumference, s the surface, and S the solidity of the sphere; then,

1. Surface $(s) = c\, d$
2. ——— $(s) = 3\cdot1416\, d^2$
3. ——— $(s) = \cdot3183\, c^2$
4. Solidity $(S) = \frac{1}{6} s\, d$
5. ——— $(S) = \cdot01688\, c^3$
6. ——— $(S) = \cdot5236\, d^3$.

Spherical Segments and Zones.

The same notation remaining, let r represent the radius of the base of the segment, and h its height; then,

1. Surface of seg. $= 3\cdot1416\, d\, h$
2. Solidity of seg. $= \cdot5236\, h\, (3 r^2 + h^2)$
3. ——— $= \cdot5236\, h\, (3 d - 2 h)$.

For the zone, put R and r for the two radii of its ends, and h its altitude; then,

4. Surface of zone $= 3.1416\, d\, h$
5. Solidity $= 1\cdot5708\, h\, (R^2 + r^2 + \frac{1}{3} h^2)$.

Circular Spindle.

Put $l = \frac{1}{2}$ length of the spindle, $m = \frac{1}{2}$ its middle diameter, a the length of the generating arc, and A the area of generating segment.

Make $\dfrac{l^2 + m^2}{2 m} = r$; then,

1. Surface of spindle $= 2 \left\{ l r - a (r - m) \right\} \times 3\cdot1416$

2. Solidity $= 4 \left\{ \frac{1}{3} l^3 - \frac{1}{2} A (r - m) \right\} \times 3\cdot1416$.

For the middle zone of a circular spindle, make L $= \frac{1}{2}$ the length of the spindle, $l = \frac{1}{2}$ the length of the zone, A the generating area, r and m being the same as above; then

3. Solidity of zone $= 2 \left\{ (L^2 - \frac{1}{3} l^2)\, l - A (r - m) \right\} \times 3.1416$

The Regular Bodies.

Let S represent the side or edge of one of the equal faces; then,

1. Tetraedron $\begin{cases} \text{Surf.} = s^2 \times 1\cdot73205 = s^2 \sqrt{3} \\ \text{Solid.} = s^3 \times 0\cdot11785 = \frac{1}{12} s^3 \sqrt{2} \end{cases}$

2. Hexaedron $\begin{cases} \text{Surf.} = s^2 \times 6\cdot00000 = 6 s^2 \\ \text{Solid.} = s^3 \times 1\cdot00000 = s^3 \end{cases}$

3. Octaedron $\begin{cases} \text{Surf.} = s^2 \times 3\cdot46410 = 2 s^2 \sqrt{3} \\ \text{Solid.} = s^3 \times 0\cdot47140 = \frac{1}{3} s^3 \sqrt{2} \end{cases}$

4. Dodecaedron $\begin{cases} \text{Surf.} = s^2 \times 20\cdot64578 = 15 s^2 \\ \qquad \sqrt{(1 + \frac{2}{5} \sqrt{5})} \\ \text{Solid.} = s^3 \times 7\cdot66312 = 5 s^3 \\ \qquad \sqrt{\dfrac{47 + 21\sqrt{5}}{40}} \end{cases}$

5. Icosaedron $\begin{cases} \text{Surf.} = s^2 \times 8\cdot66025 = 5 s^2 \sqrt{3} \\ \text{Solid.} = s^3 \times 2\cdot18169 = \frac{5}{6} s^3 \\ \qquad \sqrt{\dfrac{7 + 3\sqrt{5}}{2}} \end{cases}$

Spheroid.

Let f denote the fixed axe, and r the revolving axe; then making $3\cdot1416 = p$, and $\dfrac{f^2 \backsim r^2}{f^2} = q$; we have

1. Solidity $= \frac{1}{6} f r^2 p$

2. Surface $= f r p \left\{ 1 \mp \dfrac{A q}{2\cdot3} - \dfrac{3 B q}{4\cdot5} \mp \dfrac{3\cdot5 C q}{6\cdot7} - \dfrac{5\cdot7 D q}{8\cdot9}, \text{ \&c.} \right\}$ the upper sign having place in the oblong sphere, and the lower sign in the oblate-sphere.

If, also, we make $\dfrac{r}{f} = z$, $\sqrt{1 \backsim z^2} = s$, $m =$ the measure in degrees of the arc whose sign is s; likewise

P $= \cdot01745329\, m$ in the oblong sphere,
P $= 2\cdot30285$ log. $(s + z)$ in the oblate sphere; then

3. Surface $= \dfrac{P f + r s}{2 s} \times 3\cdot1416\, r$.

Frustums of Spheroids.

Let f represent the fixed axe, and r the revolving one; $3\cdot1416 = p$, $\dfrac{f^2 \backsim r^2}{f^2} = q$; h the height of the frustum, $\dfrac{4 q h^2}{f^2} = z$; then the frustum being cut off by two planes perpendicular to the fixed axe, one of those planes passing through the centre of the spheroid, we shall have

1. Surface $= p r h \left\{ 1 \pm \dfrac{A z}{2\cdot3} - \dfrac{3 B z}{4\cdot5} \pm \dfrac{3\cdot5 C z}{6\cdot7} \right.$

$\frac{5 \cdot 7 Dz}{8 \cdot 9}$, &c.$\}$ where A, B, C, &c. are the preceding terms, and the upper or under fign is to be ufed, according as it is the oblate or oblong fpheroid.

For the folidity, make the diameter of the greater end = D, of the lefs end = d; then

2. Solidity $= \frac{1}{12} (2 D^2 + d^2) h \times 3 \cdot 1416$.

If the fruftum be cut off by planes, one of which paffes through the fixed axe, and the other parallel to it; then putting T the tranfverfe axe, and C the conjugate of the greater end; and t and c for thofe of the lefs end;

3. Solidity $= \frac{1}{12} (2 T C + t c) h \times 3 \cdot 1416$.

Note.—For the whole middle fruftum the above refults muft be doubled.

Segments *of* Spheroids.

Let f denote the fixed axe; r the revolving axe; h the height of the fegment; then

1. *When the bafe is parallel to the revolving axe.*

$$\text{Solidity} = \frac{r^2}{f^2} (3 f \backsim 2 h) h^2 \times \cdot 5236.$$

2. *When the bafe is perpendicular to the revolving axe.*

$$\text{Solidity} = \frac{r^2}{f^2} (3 r \backsim 2 h) h^2 \times \cdot 5236$$

Elliptic Spindles.

Put the perpendicular axe of the ellipfe = a; the parallel axe = b; length of the fpindle = l; diftance of the centre of the fpindle and ellipfe = C; and area of the generating fegment = A; then

1. Solidity $= 1 \cdot 57078 \times \left\{ \frac{a^2 l^3}{3 b^2} - 4 c A \right\}$

2. Solidity $= \frac{2}{3} l \times \cdot 7854 \left\{ D^2 - 4 c \left(\frac{3 A}{l} - D \right) \right\}$

where D is the greateft diameter of the fpindle.

Paraboloid.

Let y reprefent the ordinate or femi-diameter of the bafe; x the altitude of the folid; $3 \cdot 1416 = p$; then

1. Surface $= \frac{2 p y}{12 x^2} \left\{ (y^2 + 4 x^2)^{\frac{3}{2}} - y^3 \right\}$

2. Solidity $= \frac{1}{2} p y^2 x$.

Frustums *of* Paraboloids.

Let D denote the greater diameter, d the lefs; P the parameter; and h the height of the fruftum; then

1. Surface $= \frac{(P^2 + D^2)^{\frac{3}{2}} - (P^2 + d^2)^{\frac{3}{2}}}{P} \times \frac{1}{6} p$

where $p = 3 \cdot 1416$.

2. Solidity $= \cdot 3927 h (D^2 + d^2)$.

Thefe formulæ only obtain when the bafe of the fruftum is perpendicular to the axis of the folid. For an oblique fegment, multiply the bafe by half the altitude for the content.

Parabolic Spindle.

Let m denote the middle diameter, and l the length of the fpindle; then

1. Solidity $= \cdot 418879 \, l m^2$

For the folidity of the middle fruftum.

Let d denote the diameter of the end, then the former notation remaining,

1. Solidity $= \cdot 05236 \, l (8 m^2 + 3 d^2 + 4 d m)$.

Hyperboloid.

Let a and c reprefent the femi-axes of the generating hyperbola; v the diftance of its bafe from the centre.

Alfo let $A = \frac{a^2}{\sqrt{(a^2 + c^2)}}$ be the femi-tranfverfe of another hyperbola, whofe femi-conjugate is c, the fame with that of the former.

Then find by the proper formula, the area of the fruftum of this latter hyperbola, whofe ends are diftant from the centre by v and a; multiply this area by $3 \cdot 1416$ for the furface; that is

1. Surface $= p \times \left\{ v Y - a y - A C \text{. hyp. log. of } \frac{A Y + c v}{A y + a c} \right\}$, where $p = 3 \cdot 1416$, Y and y the ordinates of the latter hyperbola.

2. Solidity $= \frac{1}{2} \text{par.}^2 \times \frac{t + \frac{2}{3} a}{t + a}$

where a = altitude, r = radius of the bafe, t the tranfverfe axis, and $p = 3 \cdot 1416$.

3. Solidity $= \frac{r^2 + d^2}{6} \times a p$

where d is the diameter, in the middle between the bafe and vertex.

Frustums *of* Hyperboloids.

Let D and d denote the femi-diameters of the two ends, a the altitude, t and c the tranfverfe and conjugate axes, $p = 3 \cdot 1416$; then

1. Solidity $= \frac{1}{3} p a \left\{ D^2 + d^2 - \frac{c^2 a^2}{3 t^2} \right\}$

2. Solidity $= \frac{1}{6} p a \left\{ D^2 + 4 \delta^2 + d^2 \right\}$

where δ is the middle diameter.

Hyperbolic Spindle.

Let A = the generating area, D the greateft diameter, L the length of the fpindle, $p = 3 \cdot 1416$; then

1. Solidity $\frac{1}{2} p \left\{ \frac{(L^2 + D^2)}{D} A - \frac{1}{3} L^3 \right\}$

2. Solidity $\frac{1}{6} p L \left\{ D^2 + \frac{(3 A - L D)}{L} 4 C \right\}$

where C is the central diftances.

To the preceding formulæ it will be proper to annex the following table of the area of circular fegments, which will be found very convenient in various problems relating to the circle and ellipfe; and with this addition, the foregoing formulæ will be found to contain all that is effentially neceffary for meafuring any plane or folid, with the exception of fome of the higher curves, which could not be conveniently reduced into a fimilar form. In thofe cafes where logarithms, fines, tangents, &c. are neceffary, fee Logarithms, Sines, &c.

6 Table

Let us now, before we conclude this article, give a few examples in order to illuſtrate the uſe of the preceding formulæ; in doing which we ſhall only ſelect a few of the moſt difficult caſes, the others being ſo extremely obvious, that no heſitation or doubt can poſſibly ariſe in their application.

Example 1.—The three ſides of a triangle are 790, 1000, and 864: required the area.

By formula 4, *for triangles, we have*

$$\text{Log. area} = \tfrac{1}{2}\left\{\begin{matrix}\log.\ \tfrac{1}{2}s + \log.\ (\tfrac{1}{2}s - a) + \log.\ (\tfrac{1}{2}s - b) \\ + \log.\ (\tfrac{1}{2}s - a)\end{matrix}\right\}$$

$$\begin{array}{rl} \text{Now}\quad 790 &= a \\ 1000 &= b \\ 864 &= c \\ \hline 2)2654 &= s \end{array}$$

$$\begin{array}{rl|rl} 1327 = & \tfrac{1}{2}s & \log.\ 1327 = & 3{\cdot}122871 \\ 537 = & (\tfrac{1}{2}s - a) & \log.\ 537 = & 2{\cdot}729974 \\ 327 = & (\tfrac{1}{2}s - b) & \log.\ 327 = & 2{\cdot}514548 \\ 463 = & (\tfrac{1}{2}s - c) & \log.\ 463 = & 2{\cdot}665581 \\ \hline & & 2) & 11{\cdot}032974 \end{array}$$

$$\text{The area} = 328474 = 5{\cdot}516487$$

Example 2.—The two diagonals of a trapezium are 30 and 40, and their angle of interſection 48°: required the area.

By formula 2, *the area* $= \tfrac{1}{2}\,\delta\,\delta'$ *ſin.* M′.

$$\begin{array}{rr} \text{ſin. } 48^\circ = & {\cdot}743145 \\ \tfrac{1}{2}\delta\delta = \tfrac{1}{2}(30 \times 40) = & 600 \\ \hline \text{The area} = & 445{\cdot}887000 \end{array}$$

Example 3.—Required the length of a circular arc, whoſe chord is 6, and radius 9.

By formula 2, *for circular arcs.*

$$\text{The area} = 2d\sqrt{q} + \frac{q}{2\cdot 3}A + \frac{3^2 q}{4\cdot 5}B + \frac{5^2 q}{6\cdot 7}C, \text{ \&c.}$$

where $q = \dfrac{v}{d}$; v being the verſed ſine, and d the diameter.

By the property of the circle we readily find the verſed ſine, $v = 9 - 6\sqrt{2} = {\cdot}51471862$, and ${\cdot}51471862 \div 18 = {\cdot}02859548$.

$$\begin{array}{rl} \text{Whence } A = 2d\sqrt{q} = & 6{\cdot}087672 \\ B = \dfrac{q}{2\cdot 3}A = & 29013 \\ C = \dfrac{3^2 q}{4\cdot 5}B = & 373 \\ D = \dfrac{5^2 q}{6\cdot 7}C = & 6 \\ \hline & 6{\cdot}117064 = \text{arc as required.} \end{array}$$

Or, by uſing formula 3, we have

$$\text{arc} = 2s + \frac{q}{2\cdot 3}A + \frac{3^2 q}{4\cdot 5}B + \frac{5^2 q}{6\cdot 7}C + \frac{7^2 q}{8\cdot 9}D, \text{ \&c.}$$

where s is the ſine of the half arc $= 3$, and $q = \dfrac{s^2}{r^2} = \dfrac{9}{81} = \dfrac{1}{9} = 0{\cdot}1111111$, &c.

$$\begin{array}{rl} \text{Whence } A = 2s & = 6{\cdot}00000 \\ B = \dfrac{q}{2\cdot 3}A & = 0{\cdot}11111 \\ C = \dfrac{3^2 q}{4\cdot 5}B & = 0{\cdot}05555 \\ D = \dfrac{5^2 q}{6\cdot 7}C & = 0{\cdot}00367 \\ E = \dfrac{7^2 q}{8\cdot 9}D & = 0{\cdot}00028 \\ F = \dfrac{9^2 q}{10\cdot 11} & = 0{\cdot}00002 \\ \hline \text{The required arc} & = 6{\cdot}11063 \end{array}$$

Example 4.—Required the area of that circular ſegment, of which the diameter is 52, and the height or verſed ſine 2.

By formula 2, *for circular ſegments.*

$$\text{Area} = 2\sqrt{dv} \times \left\{\tfrac{2}{3} - \frac{3v}{5\cdot 2d}A - \frac{5v}{7\cdot 4d}B - \frac{7\cdot 3v}{9\cdot 6d}C \text{ \&c.}\right\}$$

where v is the verſed ſine $= 2$, and the diameter $= 52$.

$$\begin{array}{rlll} +A = & \dfrac{4v\sqrt{dv}}{3} & = \tfrac{8}{3}\sqrt{104} = & 27{\cdot}1947707 \\ -B = & \dfrac{3v}{5\cdot 2d}A & = \dfrac{3}{10\cdot 26}A = & 0{\cdot}3137858 \\ -C = & \dfrac{5v}{7\cdot 4d}B & = \dfrac{5}{7\cdot 4\cdot 29}B = & 0{\cdot}0021551 \\ -D = & \dfrac{7\cdot 3v}{9\cdot 6d}C & = \dfrac{7}{3\cdot 6\cdot 26}C = & 0{\cdot}0000322 \\ -E = & \dfrac{9\cdot 5v}{11\cdot 8d}D & = \dfrac{9\cdot 5}{11\cdot 8\cdot 26}D = & 0{\cdot}0000007 \\ \hline & & \text{Negative terms} = & -0{\cdot}3159738 \\ & & \text{Area of ſegment} = & 26{\cdot}8787969 \end{array}$$

But the readieſt method of finding the area of circular ſegment is by formula 9; where the area $= d^2 \times$ by tabular number correſponding to $\dfrac{v}{d}$.

In the preſent examples $\dfrac{v}{d} = \tfrac{2}{52} = \tfrac{1}{26} = {\cdot}038\tfrac{6}{13}$, the correſponding tabular number by preceding table $= {\cdot}009940$ and ${\cdot}009940 \times 52^2 = 26{\cdot}878$, the area required.

This method, however, can only be practiſed in caſes where great accuracy is not required, unleſs the table of ſegments be very extenſive, ſuch as that given by Hutton in his Menſuration.

Note.—In thoſe caſes where the quotient is not found *exactly* in the column of heights, or verſed ſines, as in the example above, a proportional part muſt be found for the fractional part of the number; *viz.* as 1 is to the difference between the two areas correſponding to the two verſed ſines, between

between which the given number lies; ſo is the fractional part of that number to a fourth proportional, which muſt be added to the leaſt area, or ſubtracted from the greater.

Example 5.—Required the periphery of an ellipſe, the diameters of which are 24 and 18.

By formula 1, *for the ellipſe.*

$$\text{Periphery} = C \times \left\{1 + \frac{m}{2^2} - \frac{3\,m^2}{2^2 \cdot 4^2} - \frac{3^2 \cdot 5\,m^3}{2^2 \cdot 4^2 \cdot 6^2} - \frac{3^2 \cdot 5^2 \cdot 7\,m^4}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2}\ \&c.\right\}$$

where $m = 1 - \frac{c^2}{t^2}$, t and c being the tranſverſe and conjugate diameters, and C the circumference of the circumſcribing circle $= t \times 3{\cdot}1416$.

Here, then, $1 - \frac{c^2}{t^2} = {\cdot}4375 = m$.

$$\text{1ſt term} \quad 1 \quad = \quad +\,1{\cdot}00000$$

$$\text{2d term A} = \frac{m}{2^2} = \frac{m}{4} = -\,{\cdot}10938$$

$$\text{3d term B} = \frac{3\,m^2}{2^2 \cdot 4^2} = \frac{3\,m}{4^2}\,A = -\,{\cdot}00897$$

$$\text{4th term C} = \frac{3^2 \cdot 5\,m^3}{2^2 \cdot 4^2 \cdot 6^2} = \frac{3 \cdot 5\,m}{6^2}\,B = -\,{\cdot}00164$$

$$\text{5th term D} = \frac{3^2 \cdot 5^2 \cdot 7\,m^4}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2} = \frac{5 \cdot 7\,m}{8^2}\,C = -\,{\cdot}00039$$

$$\text{6th term E} = \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9\,m^5}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2} = \frac{7 \cdot 9\,m}{10^2}\,D = -\,{\cdot}00011$$

$$\text{7th term F} = \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 \cdot 11\,m^6}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2} = \frac{9 \cdot 11\,m}{12^2}\,E = -\,{\cdot}00003$$

$$\text{8th term G} = \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 \cdot 11^2 \cdot 13\,m^7}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2 \cdot 14^2} = \frac{11 \cdot 13\,m}{14^2}\,F = -\,{\cdot}00001$$

Negative terms	=	·12053
Firſt term	=	1·00000
		·87947

whence $.87947 \times 24 \times 3{\cdot}1416 = 66{\cdot}31056$, the length of the curve required.

Example 6.—Required the length of the curve of a parabola, cut off by a double ordinate to the arc, whoſe length is as 12, the abſciſs being 2.

By formula 1, *for parabolic arcs.*

$$\text{Parabolic arc} = \tfrac{1}{2}\,p\left\{q\,s + \text{hyp. log.}\,(q + s)\right\}$$

where p is the parameter $= \frac{y^2}{x} = \frac{b^2}{2} = 18$, $q = \frac{2\,y}{p} = \frac{12}{18} = \frac{2}{3}$, and $s = \sqrt{(1 = q^2)} = \sqrt{(1 + \frac{4}{9})} = 1{\cdot}2018504$, whence the required arc =

$$9 \times \left\{\tfrac{2}{3} \times 1{\cdot}2018504 + \text{hyp. log. } 1{\cdot}8675170\right\}$$

Now hyp. log. $1{\cdot}867517 = {\cdot}6251449$

$\frac{2}{3} \times 1{\cdot}2018504 = {\cdot}8012336$

		1·4263785
Multiplier		9
Parabolic arc	—	12·8374065

Example 7.—Required the length of an hyperbolic arc, beginning at the vertex, the tranſverſe diameter being 80, conjugate 60, and ordinate 10.

By formula 1, *for hyperbolic arcs.*

$$\text{Arc} = c \times \left\{A + \frac{q}{2}\,B - \frac{q^2}{2 \cdot 4}\,C + \frac{3\,q^3}{2 \cdot 4 \cdot 6}\,D - \frac{3 \cdot 5\,q^4}{2 \cdot 4 \cdot 6 \cdot 8}\,E +, \&c.\right\}$$

$$\text{where} \quad \frac{t^2 + c^2}{c^4} = q = \frac{80^2 + 60^2}{60^4} = \frac{1}{324}$$

$$A = \text{hyp. log. } \frac{y + \sqrt{(c^2 + y^2)}}{c} = {\cdot}3274501$$

$$B = \tfrac{1}{2}\left\{y\,\sqrt{(c^2 + y^2)} - c^2\,A\right\} = 10.76133$$

$$C = \tfrac{1}{4}\left\{y^3\,\sqrt{(c^2 + y^2)} - 3\,c^2\,B\right\} = 641{\cdot}796405$$

$$D = \tfrac{1}{6}\left\{y^5\,\sqrt{(c^2 + y^2)} - 5\,c^2\,C\right\} = 45698{\cdot}7933$$

E =

$$E = \tfrac{1}{8}\left\{y^7\sqrt{(c^2+y^2)} - 7\,c^2 D\right\} = 3540529{\cdot}3125$$

$$\begin{array}{rrcl|rrcl}
\text{Hence} + & A & = & {\cdot}327450 & - & \frac{q^2}{2\,.\,4} C & = & {\cdot}000764 \\
+ & \frac{q}{2} B & = & {\cdot}016607 & - & \frac{3\,.\,5\,q^4}{2\,.\,4\,.\,6\,.\,8} E & = & {\cdot}000012 \\
+ & \frac{3\,q^2}{2\,.\,4\,.\,6} D & = & {\cdot}000084 & & \&c. & = & \&c. \\
 & \text{Sum} & + & {\cdot}344141 & & \text{Sum} & - & {\cdot}000776
\end{array}$$

therefore difference $\cdot 343365 \times 30 = 10{\cdot}30095$, the arc required.

Example 8.—Required the solidity of a conic frustum of which the altitude is 16, and two diameters 20 and 30.

By formula 4, *for conic frustums.*

$$\text{Solidity} = \tfrac{1}{3}\,p\left\{D^2 + D\,d + d^2\right\} \times {\cdot}7854$$

where $D = 30$, $d = 20$, and $h = 16$.

Now $30^2 + 30\,.\,20 + 20^2 = 1900$

therefore $\frac{16}{3} \times 1900 \times {\cdot}7854 = 7625{\cdot}38$, the solidity required.

Example 9.—Required the surface and solidity of the five regular bodies, the linear side of each being 2.

By the formula for the regular bodies.

Tetraedron	Surface =	$1{\cdot}73205 \times 4 = 6{\cdot}92820$
	Solidity =	$0.11785 \times 8 = {\cdot}94280$
Hexaedron	Surface =	$6{\cdot}00000 \times 4 = 24{\cdot}00000$
	Solidity =	$1{\cdot}00000 \times 8 = 8{\cdot}00000$
Octaedron	Surface =	$3{\cdot}46410 \times 4 = 14{\cdot}65640$
	Solidity =	$0{\cdot}47140 \times 8 = 3{\cdot}77120$
Dodecaedron	Surface =	$20{\cdot}64578 \times 4 = 82{\cdot}58312$
	Solidity =	$7.66312 \times 8 = 61{\cdot}30496$
Icosaedron	Surface =	$8{\cdot}66025 \times 4 = 34{\cdot}64100$
	Solidity =	$2{\cdot}18169 \times 8 = 17.45352$

These examples will be sufficient for illustrating the use of the preceding formulæ, and for rendering their application to any other problems perfectly simple and obvious. Neither the limits of this article, nor the nature of the work, would allow of our entering upon their investigation; the reader, therefore, who is desirous of information on this head, is referred to the works of Dr. Hutton and Mr. Bonnycastle, above-mentioned.

MENSURATION *of Altitudes, Distances*, &c. See ALTITUDE and DISTANCE.

MENSURATION *of Land.* See SURVEYING.

MENSURATION *of Timber*, or *Timber Measure*, is the method employed by artificers in measuring trees, joists, beams, &c.: and as these always fall under one or other of the regular solids which have been already treated of in the preceding article, it would seem unnecessary to repeat here any rules for the mensuration of timber: but the fact is, that an erroneous rule has been adopted by persons concerned in this line of business, which common practice has so established, that it is rather to be wished than expected it should be replaced by some other, either perfectly true, or approaching towards the truth; for, according to the present rule, a tree frequently contains $\frac{1}{4}$th more or less timber than it is estimated at, which, at the modern price of that article, is a matter of some importance, and merits the attention of the timber grower, as well as the merchant. Government has, in some instances, come forward to fix a standard of measure, as in corn, coals, land, &c.; and as old prejudices can never be so successfully combated, as by the authority of enlightened legislators, it is to be hoped that we may some day find this, and other topics of a similar nature, become the subject of parliamentary investigation. We will, in the following pages, shew the great inaccuracy attending the present method, but, in the first place, it will be proper to state the rule as it is at present employed by all persons concerned in the buying or selling of timber.

GENERAL RULE.

Multiply the square of the mean quarter girt, or quarter circumference, by the length of the tree, for the contents; which, when the dimensions are taken in feet, will be also feet; and this divided by 50, the number of feet in a load, will give the number of loads.

Note—1. If the piece of timber is of the same girt throughout, the girt any where taken is the mean girt.

2. If the tree tapers regularly from one end to the other, the girt taken in the middle is accounted the mean girt; or take half the sum of the girts at the two ends for the same.

3. But if the tree do not taper regularly, but is unequal, being thick in some places and small in others; it is customary to take several different dimensions, the sum of which, divided by the number of them, is accounted the mean girt. But when the tree is very irregular, it is best to divide it into several lengths, and to find the content of each separately.

4. That part of a tree, or of the branches, whose quarter girt is less than half a foot, is not accounted timber.

5. It is usual to make a certain allowance in girting a tree for the thickness of the bark, which is generally one inch to every foot in the girt. This practice, however, is unreasonable, and ought to be discouraged. Elm timber is the only kind in which any allowance is necessary, and even in this, one inch out of the whole girt is quite sufficient.

As an example in the preceding rule: let it be required to find the content of a tree, the length of which is 9 feet 6 inches; and quarter girt 3 feet 6 inches.

	By Decimals.	By Duodecimals.
	3.5	3—6
	3.5	3—6
	175	10—6
	105	1—9
Carry forward	12.25	12—3

By Decimals.		By Duodecimals.
Brought forward	12·25	12 — 3
	95	9 · 6
	6125	110 — 3
	11025	6 — 1½
Feet	116·375 = Content = Feet	116 — 4½

Such is the rule commonly uſed by perſons concerned in buying and ſelling of timber, on which we intend to make a few remarks, in order to point out its inaccuracy, which is not ſo generally known as it ought to be. Suppoſe, for inſtance, we take a balk 24 feet long, and a foot ſquare throughout, and, conſequently, its ſolidity 24 feet. Now if this piece of timber be ſlit exactly in two, from end to end, making each piece 6 inches, or ½ a foot broad, and 12 inches, or a foot thick, it is evident that the true ſolidity of each piece will be 12 feet. But by the quarter girt method they would amount to much more: for the falſe quarter girt being equal to half the ſum of the breadth and thickneſs, in this caſe will be 9 inches, or $\frac{3}{4}$ of a foot; the ſquare of which is $\frac{9}{16}$, and therefore $\frac{9}{16} \times 24 = 13\frac{1}{2}$ feet for the ſolidity of each part, making the two pieces together 27 feet, inſtead of 24, which is the true content.

Again, ſuppoſe this balk to be ſo cut, that the breadth of the one piece may be only 4 inches, or $\frac{1}{3}$ of a foot; and that of the other 8 inches, or $\frac{2}{3}$ of a foot. Here the true content of the leſs piece will be 8 feet, and that of the greater 16 feet. But proceeding by the other method, we have the quarter girt of the leſs piece $\frac{2}{3}$ of a foot, and of the other piece $\frac{5}{6}$ of a foot. Whence the content of the leſs piece will be found $= \frac{4}{9} \times 24 = 10\frac{2}{3}$ feet, inſtead of 8 feet; and the content of the greater piece will be $16\frac{2}{3}$ feet, inſtead of 16; making the ſum of the two $27\frac{1}{3}$ feet, inſtead of 24 feet. Farther, if the leſs piece be cut only two inches broad, and conſequently the greater 10 inches, the true content of the leſs piece would be 4 feet, and that of the greater 20 feet. Whereas by the other method, the quarter girt of the leſs piece would be 7 inches, or $\frac{7}{12}$ of a foot; and $\frac{49}{144} \times 24 = 8\frac{1}{2}$ feet, inſtead of 4 feet, for the content; and by the ſame method, the content of the greater piece would be $20\frac{1}{6}$ feet, inſtead of 20, and their ſum $28\frac{1}{6}$ feet, inſtead of 24.

Hence it is obvious, that the greater the proportion is between the breadth and the depth, the greater will be the error, by uſing the falſe method; and the ſum of the two parts, by the ſame method, is greater, as the difference of the ſame two parts is greater; and, conſequently, the ſum is leaſt when the two parts are equal to each other; or when the balk is cut equally in two; and finally, when the ſides of a piece of timber differ not above an inch or two from each other, the quarter girt may be uſed without any very ſenſible error. To avoid, therefore, this inconſiſtency in the reſult, the following method ſhould be employed, *viz. Multiply the length, breadth, and depth continually together, and the product will be the true content in all caſes of this kind.*

With regard to round timber the error is of a different kind. We have ſeen in the preceding article, that the area of a circle is found by ſquaring the circumference, and multiplying that ſquare by ·07958, and, therefore, if a quarter of the circumference is uſed, we muſt multiply its ſquare by $·07958 \times 16 = 1·27328$.

Hence, to find the true content of a piece of cylindrical timber, we ought to multiply the ſquare of the quarter girt by the conſtant number 1·27328, and that product by the length, inſtead of which the conſtant multiplier is omitted, and conſequently the ſolidity is returned about [illegible] parts leſs than it is. But as the utmoſt accuracy is not neceſſary in thoſe caſes, the following rule might be uſed, which is as ſimple as can be deſired, *viz. Multiply the ſquare of* $\frac{1}{5}$ *of the mean girt by double the length for the content, which is not far from the truth.*

Another error to which timber meaſure is always ſubject, is the way in which the mean girt is aſſumed in tapering trees, which, as we have before ſtated, is done either by taking the girt in the middle, or half the ſum of the extreme girts, both of which are equally falſe, ſo obviouſly ſo, that a tree of certain dimenſions will meaſure more after a part of it has been cut off, than it did before. This being the caſe, it will not be amiſs to ſhew the extreme inaccuracy of the method, and the folly in perſiſting in it, by the ſolution of the following problems, which have been taken from Dr. Hutton's Menſuration.

Problem I.

To find where a tapering timber muſt be cut, ſo that the two parts, meaſured ſeparately, ſhall meaſure the moſt poſſible, and be greater than if it were cut in any other two parts, and greater than the whole.

Put G = the greateſt girt, g = the leaſt girt, x = the girt at the ſection, z = the length of the part to be cut off, and L the whole length of the timber. Then by ſimilar figures $L : z :: G - g : x - g$; hence $x = \frac{Gz - gz}{L} + g$: but $(g + x)^2 z + (G + x)^2 (L - z)$ is to be a *maximum;* which being put into fluxions, and reduced, gives $z = \frac{1}{2} L$.

Therefore, a tree being cut exactly in the middle, the two parts will meaſure more than if it were cut in any other two parts, and more than the whole tree. If a tree, of which the greater girt is 12 feet, and leſs girt 2 feet, and length 32 feet, be thus cut in two parts, the meaſure of the two parts will exceed the meaſure of the whole tree by 18 feet.

Problem II.

To find where a tree muſt be cut, ſo that the part next the greater end may meaſure the greateſt poſſible.

Here, by uſing the ſame notation as in the laſt problem, we have alſo $x = \frac{Gz - gz}{L} + g$, and $(G + x)^2 (L - z)$ a *maximum;* which, put into fluxions as before, gives $z = \frac{G - 3g}{G - g} + \frac{1}{3} L$.

Therefore, from the greater girt ſubtract the leſs girt, and that difference divided by the difference of the girts, and multiplied by $\frac{1}{3}$ of the whole length, will be the length to be cut off.

Problem III.

To find where a tree muſt be cut, ſo that the part next the greater end may meaſure the ſame as the whole tree before it was cut.

Uſing ſtill the ſame notation, and writing beſides s for the ſum of the two girts, and d for their difference; we ſhall have $s^2 L = (L - z)(G + x)^2$, or ſubſtituting, inſtead of x, its value $\frac{Gz - gz}{L} + g$, or $\frac{dz}{L} + g$, we obtain

$$z = \frac{L}{2d} + \left\{ \sqrt{(4s^2 + d)} - 2s + d \right\}$$

which

which length being cut off, the remaining part will measure the same as the whole tree.

These results, which are the necessary consequence of the preceding rules, are so obviously erroneous and inconsistent, that they speak for themselves, and therefore require no farther comment.

MENTAL, something that relates, or is restrained, to the operation of the understanding.

Thus, a mental prayer is such a one as is made merely in the mind, without pronouncing one word of it.

Mental reservations are the refuge of hypocrites. See RESERVATION.

MENTAL *Derangement.* Under this head may be comprehended a variety of terms, which have been employed to designate certain affections of the mind, or, as they have been called, disorders of the intellect. In the preliminary part of this investigation, it is highly important to understand fully the force and meaning of the words, which are intended to establish these different significations; and also to discover the contrivances of language, which have served to characterize the phenomena of disordered understanding. That the mind has no language peculiar to itself, seems to be an admitted axiom; because all the terms which are applied to it have their origin in the physical circumstances which surround us. The mental operations, which are supposed to be extensive, have not furnished any terms, (as the result of such internal operations,) which we did not previously possess, and which we have been compelled to borrow from the objects and impressions of the material world.

Although authors have generally divided mental derangement into *mania* aand *melancholia*, according to the system of the Greeks; yet most nations have adopted peculiar expressions, to signify the form or degree of derangement of intellect. The term *derangement*, which we have taken immediately from the French, and which means out of *rank*, or *order*, is metaphorically applied to the mind, to denote that its ideas are out of the rank, or order, generally preserved by intelligent beings. *Delirium*, employed by the Romans, had its origin from the process of ploughing: for when the oxen deviated from the line to be pursued, they were said to be *de lira*, out of the track; and this figure was transferred to the deviations of the human intellect, when it erred from the established course. *Insane*, *insanus*, means merely *unsound.* The Greek μανία was probably from their verb μαίνομαί, *I rage;* μελανχολια, from μελας, *black*, and χολὴ, *bile;* black bile being supposed the cause of this disease. In the opinion of Cicero, (Disputat. Tusculan. lib. iii. c. 5.) the Roman terms, which marked the disorders of the intellect, were more appropriate than those employed by the Greeks. "Multoque melius hæc notata sunt verbis Latinis, quam Græcis: quod aliis quoque multis locis reperietur. Sed id alias: nunc, quod instat. Totum igitur id quod quærimus, quid et quale sit, verbi vis ipsa declarat. Eos enim sanos quoniam intelligi necesse est, quorum mens motu, quasi morbo, perturbata nullo sit; qui contra affecti sunt, hos insanos appellari necesse est. Itaque nihil melius, quam quod est in consuetudine sermonis Latini; cum *exisse ex potestate* dicimus eos, qui effrenati feruntur aut libidine aut iracundia: quamquam ipsa iracundia libidinis est pars: sic enim definitur, *iracundia ulciscendi libido.* Qui igitur *exisse ex potestate* dicuntur; idcirco dicuntur, quia non sunt in potestate mentis: cui regnum totius animi a natura tributum est. Græci autem μανίαν unde appellant, non facile dixerim. Eam tamen ipsam distinguimus nos melius, quam illi; hanc enim insaniam, quæ juncta stultitiæ patet latius, a furore disjungimus: Græci volunt illi quidem, sed parum valent verbo: quem nos furorem, μελανχολίαν illi vocant. Quasi vero atra bili solum mens, ac non sæpe vel iracundia graviore, vel timore, vel dolore moveatur! quo genere Athamantem, Alcmæonem, Ajacem, Orestem furere dicimus. Qui ita sit affectus, eum dominum esse rerum suarum vetant duodecim tabulæ." The supposed regulation of the intellect, in certain states, by the influence of the moon, has produced the term *lunatic;* which word still prevails in all legal proceedings relative to the insane. The vulgar opinion, that in madness the mind was broken into fragments, has given rise to the terms *crazy* (*ecrasé*, Fr.), *cracked*, and *shatter-brained.* The word *mad* has been derived by Mr. Haslam ("Observations on Madness and Melancholy") from the Gothic *mod*, which signifies *rage.* He observes, "It is true, we have now converted the *o* into *a*, and write the word *mad;* but *mod* was anciently employed." Of the similarity between violent anger and madness, the observation has been general. Cicero says, "An est quicquam similius insaniæ quam ira? quam bene Ennius initium dixit insaniæ." (Disp. Tusc.) Dr. Beddoes (Hygeia, N° 12.) observes, that "*mad* is one of those words which means almost every thing and nothing. At first, it was, I imagine, applied to the transports of rage; and when men were civilized enough to be capable of insanity, their insanity, I presume, must have been of the frantic sort; because, in the untutored, intense feelings seem regularly to carry a boisterous expression."

Authors, who have treated on the subject of mental derangement, have commonly been desirous of affording a definition: they have endeavoured to compress into a few words, or a short sentence, the prominent and discriminating phenomena of insanity, and thus to establish an essential character of the disorder. However meritorious their labours, their success has been by no means proportionate to their exertions. They have all fundamentally differed; and to enumerate their attempts is only to record their failures. Dr. Mead conjectures, "that this disease consists entirely in the strength of imagination." "Insanity," says Dr. Cullen, "consists in such false conceptions of the relations of things as lead to irrational emotions or actions. Melancholy is partial insanity, without indigestion; mania is universal insanity." Dr. Ferriar, adopting the generally accepted division of insanity into mania and melancholia, conceives, in mania, *false perception*, and consequently confusion of ideas, to be a leading circumstance. Melancholia he supposes to consist in *intensity of idea*, which is a contrary state to false perception. Dr. Arnold observes, that "insanity, as well as delirium, may be considered as divisible into two kinds; one of which may be called *ideal*, and the other *notional insanity.*

"*Ideal insanity* is that state of mind, in which a person imagines he sees, hears, or otherwise perceives, or converses with, persons or things, which either have no external existence to his senses at the time; or have no such external existence, as they are then conceived to have; or if he perceives external objects as they really exist, has yet erroneous and absurd ideas of his own form, and other sensible qualities:—such a state of mind continuing for a considerable time, and being unaccompanied with any violent or adequate degree of fever.

"*Notional insanity* is that state of mind, in which a person sees, hears, or otherwise perceives external objects, as they really exist, as objects of sense; yet conceives such notions of the powers, properties, designs, state, destination, importance, manner of existence, or the like, of things and persons, of himself and others, as appear obviously, and often grossly erroneous, or unreasonable to the common sense of the sober and judicious part of mankind. It is of considerable confiderable duration; is never accompanied with any great degree of fever, and very often with no fever at all."

Mr. Haflam, in the firft edition of his work (Obfervations on Infanity), defined infanity to be "an incorrect affociation of familiar ideas, which is independent of the prejudices of education, and is always accompanied with implicit belief, and generally with either violent or depreffing paffions." But the fame author, in his fecond edition, has omitted this definition, and feems to be convinced that, inftead of endeavouring to difcover an infallible definition of madnefs, which he believes will be found impoffible, (as it is an attempt to comprife in a few words the wide range and mutable character of this Proteus-diforder,) much greater advantage would be obtained, if the circumftances could be precifely defined, under which it is juftifiable to deprive a human being of his liberty.

Symptoms.—The approaches of infanity have been varioufly related by different writers. The late Dr. John Monro, in a pointed and elegant reply to Dr. Battie's Treatife on Madnefs, has remarked, that "high fpirits, as they are generally termed, are the firft fymptoms of this kind of diforder: thefe excite a man to take a larger quantity of wine than ufual; (for thofe who have fallen under my obfervation, in this particular, have been naturally very fober;) and the perfon thus affected, from being abftemious, referved, and modeft, fhall become quite the contrary; drink freely, talk boldly, obfcenely, fwear, fit up till midnight, fleep little, rife fuddenly from bed, go out a hunting, return again immediately, fet all his fervants to work, and employ five times the number that is neceffary: in fhort, every thing he fays or does betrays the moft violent agitation of mind, which it is not in his power to correct; and yet, in the midft of all this hurry, he will not mifplace one word, or give the leaft reafon for any one to think he *imagines* things to exift that really do not, or that they appear to him different from what they do to other people. They who fee him but feldom, admire his vivacity, are pleafed with his fallies of wit, and the fagacity of his remarks: nay, his own family are with difficulty perfuaded to take proper care of him, until it becomes abfolutely neceffary, from the apparent ruin of his health and fortune."

In many inftances, pain of the head and throbbing of its arteries precede an attack of infanity: fometimes giddinefs and confufed vifion are complained of, as precurfory fymptoms. Thofe who have been feveral times difordered are now and then fenfible of the return of their malady. Some have defcribed the attack as highly delightful; and of this pleafurable feeling, a curious inftance is recorded in the Bibliotheque Britannique, by a recovered lunatic, who had been a patient of the late Dr. Willis. "I always expected with impatience the acceffion of the paroxyfms, fince I enjoyed, during their prefence, a high degree of pleafure. They lafted ten or twelve hours. Every thing appeared eafy to me. No obftacles prefented themfelves either in theory or practice. My memory acquired, all of a fudden, a fingular degree of perfection: long paffages of Latin authors occurred to my mind. In general, I have great difficulty in finding rhythmical terminations; but then I could write in verfe with as much facility as in profe. I was cunning, malicious, and fertile in all kinds of expedients." Some have defcribed a fenfe of working in the head, and alfo in the inteftines, as if they were in a ftate of fermentation. Others obferve that they do not feem to poffefs their natural feelings; and they all agree that they become confufed, from the fudden and rapid intrufion of unconnected thoughts.

Mr. Haflam, whofe fituation in Bethlem Hofpital affords abundant opportunities of obferving this diforder, has thus related the commencement of madnefs and melancholy. "On the approach of mania, they firft become uneafy, are incapable of confining their attention, and neglect any employment to which they have been accuftomed. They get but little fleep; they are loquacious, and difpofed to harangue, and decide promptly and pofitively upon every fubject that may be ftarted. Soon after, they are diverted of all reftraint, in the declaration of their opinions of thofe with whom they are acquainted. Their friendfhips are expreffed with fervency and extravagance; their enmities with intolerance and difguft. They now become impatient of contradiction, and fcorn reproof. For fuppofed injuries, they are inclined to quarrel and fight with thofe about them. They have all the appearance of perfons inebriated; and thofe, who are unacquainted with the fymptoms of approaching mania, generally fuppofe them to be in a ftate of intoxication. At length fufpicion creeps upon the mind, they are aware of plots which had never been contrived, and detect motives that were never entertained. At laft, the fucceffion of ideas is too rapid to be examined; the mind becomes crowded with thoughts, and confufion enfues. Thofe under the influence of the depreffing paffions will exhibit a different train of fymptoms. The countenance wears an anxious and gloomy afpect; and they are little difpofed to fpeak. They retire from the company of thofe with whom they formerly affociated; feclude themfelves in obfcure places, or lie in bed the greater part of their time. Frequently, they will keep their eyes fixed to fome object for hours together, or continue them an equal time 'bent on vacuity.' They next become fearful, and conceive a thoufand fancies: often recur to fome immoral act which they have committed, or imagine themfelves guilty of crimes which they never perpetrated; believe that God has abandoned them, and with trembling await his punifhment. Frequently they become defperate, and endeavour by their own hands to terminate an exiftence, which appears to be an afflicting and hateful incumbrance."

The mental characteriftics of this diforder involve all thofe aberrations from intellectual foundnefs, and moral rectitude, which render man a worthlefs, and frequently a dangerous affociate to the community. A degree of cunning, infcrutable by ordinary perfons, and not always to be penetrated by thofe who have acquired extenfive experience of the infane, conftitutes a leading feature in mental derangement. Whenever they have meditated their own deftruction, or intended mifchief to others, the accomplifhment of the deed has often been the only notice of the intention; and the pride, which ufually accompanies this malady, has frequently induced thefe unhappy fufferers to haunt the perfons of thofe diftinguifhed by rank and elevated in office.

The bodily marks which diftinguifh the infane, are, a peculiar caft of countenance, familiar to, and recognizable by thofe verfed in this difeafe; a quick, oftentimes protruded and gliftening eye; coldnefs of the hands and feet; and a capability of fuftaining cold with impunity. But Dr. Pinel, phyfician to the Bicétre at Paris, conceives this exception from the effects of fevere cold to be by no means general, and inftances the frequent occurrence of mortified extremities during winter; and others of much experience are of the fame opinion. Obftinate conftipation has been mentioned as an unvarying attendant on madnefs; but the beft informed writers regard it merely as an occafional fymptom, prevailing only when general infenfibility is the confequence of preffure on the brain. In deranged perfons, the ear is the organ of fenfe moft af-

fected;

fected; *tinnitus aurium* and deafnefs being found very generally to prevail: whereas blindnefs, or deprivations of the fmell and tafte, have been feldom noticed. Mr. Haflam has exclufively obferved, in fome cafes, a relaxation of the fcalp; by which it may be wrinkled, or rather gathered up by the hand to a confiderable degree: it more generally occurs on the pofterior part; is not noticed in the early ftages of the difeafe, but after a raving paroxyfm of fome continuance.

Appearances on Diffection.—From the teftimonies of Chiarugi in Italy, Greding in Germany, and from Mr. Haflam's work, difeafed appearances of the brain and its membranes have been detected in thofe who have died infane. But there may exift many alterations in the ftructure of thefe parts, too minute for the eye to obferve, and which can never be brought in view by the fcalpel. Although Dr. Pinel denies the diforganifation of the brain in madnefs as peculiar to that difeafe; yet he admits, that the fame appearances are found, as occur in thofe who have died from epilepfy, apoplexy, fever, and convulfions. Thefe morbid appearances confift in exceffive determination of blood to the brain, with enlargement of its veffels, and effufion of fluids into its cavities. In many inftances the fubftance of the brain has poffeffed an increafed degree of firmnefs, and, according to the late Mr. John Hunter, has been found fo tough, as to have fome elafticity. Dr. Baillie has alfo remarked, that "when thefe changes take place in the brain, the mind is at the fame time deranged; there is either mania or lethargy; or the perfon is much fubject to convulfive paroxyfms." In other cafes the brain was of a preternaturally foft confiftence. Gangrene of the brain has fometimes occurred, but more frequently in the warmer climates, as may be feen by confulting Chiarugi. The membranes of the brain have been found varioufly altered from their healthy ftate: the tunica arachnoidea has become thickened, and rendered more or lefs opaque. The pia mater is often inflamed, and turgid with blood, and not unfrequently an extravafated blotch appears on fome part of this tunic. Effufion of a watery fluid between the membranes of the brain is a very common occurrence, and likewife into its ventricles, which have been confequently enlarged to a furprifing extent. Offifications have been detected, but principally on the dura mater.

Caufes.—In the inveftigation of the caufes of mental derangement, there is obvioufly much uncertainty; our knowledge of the human mind is too limited to affirm that particular ftates of the intellect will be the neceffary refult of certain circumftances preceding. Thofe who have attentively confidered this fubject have divided the caufes of infanity into *phyfical* and *moral*. Under the head of *phyfical* caufes, hereditary difpofition has been ftated very generally to prevail; whereby the offspring of an infane parent, or parents, will moft probably become fimilarly affected; but, whether this tranfmiffion depend more efpecially on the male, or female, has not yet been certainly determined. Injuries to the head from external violence; frequent intoxication, particularly when produced by fermented liquors which have undergone the procefs of diftillation; fever, during the courfe of which delirium has particularly prevailed; mercurial medicines, largely exhibited, and continued for a confiderable time, without due precautions; paralytic affections (but thefe are very frequently the confequence as well as the caufe of mental derangement); the fuppreffion of periodical or occafional difcharges and fecretions; and, in fome inftances, the retropulfion of cutaneous eruptions; are the ordinary phyfical caufes to which infanity has been afcribed.

The *moral* caufes include thofe emotions which are conceived to originate from the mind itfelf, and which, from their excefs, tend to diftort the natural feelings, or, from their repeated acceffions, and unreftrained indulgence, at length overthrow the barriers of reafon and eftablifhed opinion. Such are the gufts of violent anger, and the protracted indulgence of grief; the terror impreffed by erroneous views of religion; the degradation of pride; difappointment in love; and fudden fright.

Although mental derangement has been obferved in perfons of all habits and complexions, yet there is doubtlefs a temperament which particularly difpofes to infanity: and there are alfo certain modes of education, and employment of the faculties, which conduce to their derangement. According to Mr. Haflam's ftatement, out of 265 patients in Bethlem Hofpital, 205 were found to be of a fwarthy complexion, with dark or black hair; the remaining 60 were of a fair fkin; with light, brown, or red hair. Dr. Pinel, on examining the regifters of the Bicétre, fays, that he found infcribed a great many monks and priefts, as alfo a confiderable number of country people, who had been driven befide themfelves by horrid pictures of futurity; feveral artifts, as fculptors, painters, and muficians; fome verfifiers, in extacies with their own productions; a pretty confiderable number of advocates and attornies; but there does not appear the name of a fingle perfon accuftomed to the habitual exercife of his intellectual faculties; not one naturalift, or natural philofopher of ability; no chemift nor geometrician.

The *prognofis*, or means of afcertaining the probable event of mental derangement, is founded on the experience of thofe practitioners who have particularly attended to the treatment of this diforder. It is, however, to be lamented, that very few of thofe perfons, who have been beft qualified to afford information, have tranfmitted to the world the refult of their practice. Much valuable knowledge may therefore be prefumed to have perifhed. In the year 1758 Dr. Battie, the phyfician to St. Luke's Hofpital, juftly obferved in his "Treatife on Madnefs," that "among the many good reafons, offered to the public for eftablifhing another hofpital for the reception of lunatics, one, and that not the leaft confiderable, was the introducing more gentlemen of the faculty to the ftudy and practice of one of the moft important branches of phyfic." In England, females are more fubject to infanity than men; but abroad, the cafe is believed to be reverfed. From 1748 to 1794, a period of 46 years, there were admitted into Bethlem Hofpital 4832 women, and 4042 men. Dr. Chiarugi of Florence, who, during four years, faw in the hofpitals of St. Dorothea and St. Bonifacio 1157 lunatics, ftates the proportion of deranged males, as exceeding that of females by one-fifth. Females recover from mental derangement in a greater proportion than men: of the above mentioned 4832 women, 1402 were difcharged cured; of the 4042 men, 1155 recovered.

As infanity frequently fupervenes on parturition, women, becoming deranged from fuch caufe, recover in a very large proportion. During ten years, 80 patients of this defcription were admitted into Bethlem Hofpital, 50 of whom perfectly recovered. When females become worfe at the period of menftruation, or have their catamenia in profufe or deficient quantities, fuch occurrences may be confidered unfavourable.

The chance of recovery is greater when the patient is attacked with mania, than when affected with melancholia. When the maniacal and melancholic ftates alternate, the hope of recovery is diminifhed. A greater number of patients are obferved to recover, when the mental derange-

ment

ment has been produced from remote *physical* causes, than when it has arisen from causes of a *moral* nature.

It appears from the united testimonies of Dr. Pinel and Mr. Haslam, that a greater number of insane patients have been admitted into the Bicêtre, and Bethlem Hospital, from the age of 30 to 40, than during any other equal period of life; and from the statement of the latter, it may be inferred, that the disease is less frequently cured when it attacks persons of an advanced age. The following statement comprises the number of patients admitted into Bethlem Hospital from 1784 to 1794. The first column marks the age: the second the number admitted; the third notes the number cured; the fourth those who were discharged not cured.

Age between.	Number admitted.	Number discharged cured.	Number discharged uncured.
10 and 20	113	78	35
20 — 30	488	200	288
30 — 40	527	180	347
40 — 50	362	87	275
50 — 60	143	25	118
60 — 70	31	4	27

It is also calculated, that the chance of cure is diminished, in proportion to the length of time which the disorder has continued.

Where mental derangement is complicated with palsy or epilepsy, or where the natural powers of the mind become enfeebled during its continuance, there is but little hope of the patient's recovery. The insanity, which is often excited by the impression of religious terror,—by those gloomy views of futurity, and that constant dread of divine vengeance which false notions on this subject usually inspire,—has seldom a favourable termination. When the derangement has acquired a systematic character, it becomes very difficult to remove: in this state, incidents the most unconnected are easily reconciled, and become fondly involved with the prevailing delusion.

The *Cure* of mental derangement may properly be divided into *management* and *medicine:* for it appears to be the opinion of those who have most successfully treated this disorder, that the proper controul and subjection of the patient to salutary and established rules are of equal importance with the prescription of remedies.

By the common consent of foreigners, the English are supposed particularly to excel in the moral management of this disorder. It is, however, to be regretted, that general directions only can be given on this subject: the precise adaptation of these principles to individual cases, must depend on the skill, address, and experience of the practitioner.

Insane persons are most advantageously treated when removed from home, and from the interference of their immediate relations and friends. While they remain in their own houses, it is nearly impossible to divest them of the authority which they had been accustomed to maintain; and the salutary regulations of the superintendant are frequently rendered useless, by the mistaken indulgence of their family connections. A system of regularity should be established in their actions; and restraint should instantly be imposed on disobedience. As the deranged person should be taught to view the superintendant of his conduct with respect, the latter should be careful to deserve it by vigilant firmness, and steady decorum. The confidence of the maniac can never be reposed in ignorance and mismanagement, nor can his esteem be imparted to unfeeling and tyrannical assumption. Although it is proper to curb the extravagant sallies of the patient; yet no advantage appears to be derived from an endeavour to convince him by argument; the less frequently the subjects of his delusion are referred to, the more easily he becomes managed. When the insane are convalescent, the occasional visits of their friends are attended with manifest advantage: such intercourse brightens the prospects of future life, and often acts as a stimulus to self-restraint. But in certain states of the disorder, where pride, malevolence, and cunning, form the leading features of derangement, the ill-timed admission of friends has been signally prejudicial: it has tended to unfix the authority of the superintendant, and introduced a train of associations which has aggravated the malady. Of the beneficial effects of mild and humane treatment in this disorder, Mr. Haslam says, "Speaking of the effects of management on an extensive scale, I can truly declare, that by gentleness of manner, and kindness of treatment, I have seldom failed to obtain the confidence and conciliate the esteem of insane persons; and have succeeded by these means in procuring from them respect and obedience. There are certainly some patients who are not to be trusted, and in whom malevolence forms the prominent feature of their character: such persons should always be kept under a certain restraint, but this is not incompatible with kindness and humanity."

Deception on the part of the medical superintendant should never be resorted to. The late Dr. John Monro emphatically observes, "The physician should never deceive them in any thing, but more particularly with regard to their distemper; yet as they are generally conscious of it themselves, they acquire a kind of reverence for those who know it, and by letting them see that he is thoroughly acquainted with their complaint, he may very often gain such an ascendant over them, that they will readily follow his directions." Formerly coercion was employed with a degree of severity, that amounted to vindictive punishment: recourse was had to the whip, and stripes were actually inflicted by medical direction. The more rational and humane treatment of modern practitioners, has induced them to employ coercion only as a protecting restraint; to guard the patient from doing mischief to himself, or offering violence to others; and for this purpose the straight-waistcoat is usually sufficient.

Medicine.—An enumeration of all the remedies which have been proposed, and strongly recommended for the cure of mental derangement, would extend this article to an unprofitable length. The ancient physicians principally confided in a species of hellebore, which was cultivated with the greatest attention, prepared with the utmost care, and exhibited under particular cautions; but concerning these matters there was unfortunately much diversity of opinion. Considering the various and opposite states of mental derangement, a rational mind would scarcely expect any particular drug to possess powers adequate to the restoration of reason. If insanity be a disease of the *mind itself*, corporeal remedies can be of little utility; if an affection of the brain, and nervous system, no particular medicine can be supposed capable of restoring the various lesions, which anatomical investigation has detected.

When the experience of eminent practitioners is at variance; when remedies, which have been extolled for their virtues and successful operation by one medical writer, have been asserted by another to be impotent and unprosperous, the subject of cure becomes entangled with insuperable difficulties. Modern practitioners are nearly agreed, that at the commencement of this disorder, *bleeding* may be employed with advantage; and drawing blood by cupping-glasses has been usually preferred. Little difference of opinion has prevailed

vailed concerning the utility of *cathartics:* some practitioners have, however, preferred particular articles of this tribe, as elaterium, calomel, jalap, &c.; while others have succeeded with the milder purgatives, as senna, and the solutions of neutral salts, with the addition of a small quantity of the antimonium tartarizatum. As recovery is often preceded by a spontaneous diarrhœa, purgative medicines may be esteemed, under a judicious exhibition, of signal utility in most cases of mental derangement.

Emetics.—Practitioners are much divided in opinion respecting the propriety of administering vomits as a remedy for insanity. The late Dr. John Monro thought "the evacuation by vomiting infinitely preferable to any other." Dr. Cox is equally partial to emetics as a cure for mental derangement. Mr. Haslam, however, entertains an unfavourable opinion of them: he states that, in some instances, paralytic affections have supervened within a few hours after the exhibition of an emetic; more especially when the patient has been of a full habit, and has had the appearance of an increased determination to the head. Perhaps in melancholia, emetics may be more generally advantageous; and in furious mania, the same remedies may be employed merely in nauseating doses, to prevent the severe convulsion of vomiting.

Opium has seldom procured sleep, when given in the furious state of insanity. Notwithstanding the encomium of this remedy by Bernard Heute, the respectable testimonies of Dr. Ferriar and others have not induced any expectation of benefit from its employment. Dr. Chiarugi deposes to the sedative effect of a watery solution of opium, applied to the internal membrane of the nose with a camel's-hair pencil. Of the remaining tribe of narcotic remedies we have little that is satisfactory on record.

Digitalis, though strongly recommended by some, has produced no benefit in the hands of others. Dr. Ferriar expressly states, "that he has given this remedy, even to nauseating doses; but with no advantage. It never suspended the appearances of insanity for a moment."

Camphor has been much extolled for its virtues in mental derangement; but Dr. Ferriar and Mr. Haslam, who gave it in large doses, did not experience any considerable benefit from the employment of this remedy. Dr. Laughter mentions nine cases of insanity cured by camphor; but in these instances it was combined with vinegar. Dr. Leopold Avenbrugger, in a curious tract entitled "Experimentum noscens de remedio specifico, sub signo specifico in mania virorum," Vienna, 1772, has spoken still more highly of the specific virtues of camphor in this disease. *Blisters* have had their advocates; but it seems to be the opinion of those whose experience has been most extensive, that they succeed better when put to the lower extremities, than applied directly to the head. Issues and setons may in many cases be used with advantage; but they should be allowed to discharge for a considerable time; as their beneficial effects are not immediately apparent.

In some instances the *warm bath* has mitigated the fury of the patient, and in melancholia the use of the *cold bath* has been thought advantageous.

It appears to be a radical defect in almost all the institutions for the insane, that no plan for the *employment* of the patients has been hitherto adopted. Many difficulties certainly occur, as to the nature of the labour in which they ought to be engaged; but a judicious contrivance might surmount them, and appropriate a salutary exercise and amusement to the different classes of the insane.

MENTCHIKOF, Alexander, in *Biography*, a statesman and general under the czar Peter I., was the son of peasants who were the vassals of the monastery of Cosmopoli. At the age of thirteen he went to Moscow to obtain the means of subsistence, and was taken into the service of a pastrycook, who employed him to vend his goods by crying them about the streets of that then celebrated city, now, alas, [Oct. 1812,] desolated by the madness of war. The czar happened one day to hear him, and being struck with the pleasant song which he annexed to his cry, entered into conversation, and, in the end, ordered him to come to court, where he was at first placed in a very low station, but his talents were discoverable in the midst of all disadvantages, and it was seen he had a wonderful facility in acquiring several languages. The czar took him to serve about his person, and he was from that time gradually advanced to the highest employments, till at length he became one of the most successful generals in the Russian army. When Peter went on his travels for improvement, he took Mentchikof for his companion, and, in 1706, he was created a prince of the German empire, and was, after this, frequently employed on occasions of ceremony to personate the czar, who chose rather to appear as a private person in his train. He was victorious over the Swedes, in the war against Charles XII., and had the command of the left wing of the Russians at the decisive battle of Pultowa, in the year 1709. His situation enabled him to acquire great wealth, but in 1715 he was called to an account for certain abuses of the administration, and fell under the censure of his sovereign. He was afterwards restored to his favour, and even placed at the head of the council of regency, when Peter set out on his expedition to Persia. He greatly contributed to the succession of the empress Catherine at the death of Peter, and upon her demise he took measures to insure the crown to Peter Alexievitch, on condition that he should espouse his eldest daughter. The accession took place in 1727, and Peter was betrothed to his intended bride. Mentchikof now assumed all the arrogance of uncontrollable sway, which in a very short time occasioned an order for his arrest: this was followed by a decree of banishment. It was intended to confine him to his own estate; he imprudently left the capital with a splendid train, which his enemies construed into marks of contempt for the emperor, who readily dispatched an order to carry him prisoner to Siberia. The place of his confinement was Beresof, on the rude and desolate banks of the Oby. His wife, who had been delicately brought up, wept herself blind, and expired in the course of her journey. His own mind soon accommodated itself to his situation. He cultivated a small farm, and, by industry and frugality, saved enough from his daily pittance, of ten rubles, to build a wooden church, in the erection of which he assisted with his own hands. He died in November 1729, little more than two years from the time of his banishment. Univer. Hist.

MENTHA, in *Botany*, an ancient Latin word, mostly written Menta, adopted from the Greeks, whose μινθη is synonimous with their ἡδυοσμος, the latter being most generally used; see Dioscorides, book 3. chap. 41. The nymph Mintha, a favourite of Pluto, is fabled to have been changed by Proserpine into this herb, as incidentally mentioned by Ovid; Metam. book 10. 729.—Mint.—Linn. Gen. 291. Schreb. 387. Willd. Gen.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, erect, with five nearly equal teeth, permanent. *Cor.* of one petal, erect, tubular, somewhat longer than the calyx; limb in four deep, nearly equal, segments, the uppermost only being rather the broadest, and cloven. *Stam.* Filaments four, awl-shaped, erect, distant, the two nearest ones longest; anthers roundish. *Pist.* Germen superior, four-cleft; style thread-shaped, erect, longer than the corolla; stigma in two divaricated divisions. *Peric.* none, except the permanent straight calyx. *Seeds* four, small, generally abortive.

Ess. Ch. Calyx five-cleft, nearly equal. Corolla nearly equal, four-cleft; its broadest segment cloven. Stamens erect, distant.

This is one of the most natural genera possible; well marked in habit and characters. The herbage, and even the flowers, abound with resinous dots, the seat of an essential oil, on which the warm and aromatic qualities of these plants depend. Their flavour is different in the different species, and variable in the same, but on the whole almost peculiar to the genus. The following characters apply to the species in general. *Root* creeping, perennial. *Stems* square, branched, leafy. *Leaves* opposite, simple, undivided, generally serrated. *Flowers* in stalked many-flowered whorls, which are either axillary, capitate, or spiked. *Calyx* striated, or ribbed, rather dilated upward, almost regular, either naked, or clothed more or less completely with simple hairs, whose direction differs in different species, but is very constant in the same. Very rarely this part is covered with soft downy pubescence. *Corolla* funnel-shaped, purplish. *Stamens* inserted into its tube; when perfect generally longer than the limb. *Herbage* generally more or less hairy.

Mentha is principally an European and British genus. There are however some American and even East Indian species. Those of our own country have always been found extremely difficult to determine. Neither the shape of the leaves, general pubescence, length of the stamens, nor even the inflorescence, all which have been resorted to by botanists, has been found constant or certain. The writer of this article first proposed a mode of distinction, founded on the pubescence of the calyx and flower-stalks, and its various direction. By this clue all the British species are settled in the Transactions of the Linn. Soc. and Fl. Brit. above quoted, and we shall here apply it to the exotic ones. For want of having received information of this mode of discrimination, Willdenow has greatly failed in his view of the species. The same may, in some measure, be said of Mr. Sole of Bath, who published, in 1798, a Botanical Arrangement of the British Mints, in folio, with 24 plates; a work nevertheless of much original observation, and more correct as to species than most that had preceded it; though no attention is paid by his draughtsman to the pubescence of the calyx, in which respect no dependence whatever can be placed on his figures.

1. M. *auricularia.* Ear Mint. Linn. Mant. 81. Mat. Med. ed. 4. 169. Dale Pharmac. 160. Stokes Mat. Med. v. 3. 310. (M. fœtida; Burm. Ind. 126. Majana fœtida; Rumph. Amboin. v. 6. 41. t. 16. f. 2.)—Spikes tapering, close, hairy. Leaves ovate, coarsely serrated; hairy and green on both sides. Bracteas ovate.—Native of the East Indies. We have it from China, as well as from Java. The *stem* is densely clothed with long, shaggy, tawny, horizontal hairs. *Leaves* on very short hairy stalks, ovate or somewhat oblong, bluntish, coarsely and unequally serrated, from one to two inches in length, various in breadth; bright green above, and clothed with numerous, scattered, silky hairs; a very little paler beneath, finely dotted, not at all hoary, the ribs and veins extremely hairy. *Spikes* solitary, terminal, an inch or two long, tapering, close and uninterrupted; each whorl accompanied by a pair of opposite, ovate, fringed *bracteas*, each pair crossing the next. *Flowers* crowded, small, nearly sessile. *Calyx* bell-shaped, spreading, with five broad blunt teeth, which are fringed with numerous hairs, the rest of the calyx being smooth and even, besprinkled with shining glandular dots. *Corolla* twice as long as the calyx, somewhat hairy. *Stamens* a little prominent.—This herb is celebrated as a powerful remedy for deafness. We have already mentioned, see HEDYOTIS, that Linnæus confounded it, at one time, with our second species of that genus, than which few plants can be more distinct.

2. M. *quadrifolia.* Downy Four-leaved Mint. Rottl. MSS.—Leaves linear-lanceolate, serrated, downy on both sides; those of the stem four in a whorl. Spikes cylindrical, very long, close, hairy. Bracteas linear-lanceolate.—Sent by Dr. Rottler from Madras. The whole *plant* is clothed with dense velvet-like down. *Stem* nearly round, with whorled branches. The *leaves* on the latter are opposite only; those of the stem four in each whorl; all narrow, bluntish, with shallow serratures. *Spikes* terminal, solitary, cylindrical, very close, the principal one about six inches long, those of the branches much smaller. *Bracteas* lanceolate, or linear, minutely hispid. *Flowers* innumerable, crowded. *Calyx* bell-shaped, even, most hairy in its upper part, especially about the teeth. *Corolla* hairy. *Stamens* and *style* prominent.—We are much inclined to suspect this may be the *Stoechado-mentha,* Linn. Zeyl. 194, Mentha zeylanica camphorata hirsuta, Burm. Zeyl. 157; but the descriptions of the inflorescence, in these works, do not accord with our plant; the spikes or heads being there implied, if not positively said, to be short, whereas in our specimen they are remarkably long.

3. M. *verticillata.* Smooth Whorl-leaved Mint. Rottl. MSS.—Leaves linear-lanceolate, serrated, smooth, all whorled. Spikes solitary, cylindrical, somewhat interrupted. Calyx longer than the bracteas, with blunt, spreading, very hairy teeth.—Sent by Dr. Rottler from Madras. The *herbage* is nearly smooth. *Stem* striated, almost round, tumid above and below each joint, with whorled *branches* and *leaves.* The latter are linear, tapering at each end, furnished with shallow distant serratures. *Spikes* terminal, solitary, cylindrical, from one to two inches long; their whorls tumid and slightly interrupted, with short concealed *bracteas.* *Calyx* funnel-shaped, clothed in its upper half with copious short dense hairs; the teeth obtuse and widely spreading; the inside smooth. *Corolla* very small, whitish, hairy. Only one *seed* seems to come to perfection, and this is large, globose and smooth.

4. M. *stellata.* Stellated Cluster-spiked Mint. Lour. Cochinch. 361. *Rau ngu hoang* of the Cochinchinese.—Leaves oblong, obtuse, serrated, smooth, four in a whorl. Spikes clustered, oblong.—Found by Loureiro in moist uncultivated ground in Cochinchina. *Stem* a foot high, with four furrows. *Leaves* stellated, four in a whorl. *Flowers* minute, pale violet. *Calyx* erect, with sharp teeth. *Stamens* surrounded about the middle with long hairs. *Seeds* four, roundish.—We know nothing of this species but from the author quoted. The clustered *spikes* mark it as distinct from the last.

5. M. *incana.* Hoary Slender-spiked Mint. Sole MSS. Donn. Cant. ed. 5. 142. (M. chalepensis; Mill. Dict. ed. 8. n. 10. Menthastrum chalepense angustifolium, raro florens; Boerh. Lugd-Bat. ed. 2. v. 1. 185.)—Leaves ovate-oblong, serrated, nearly sessile, very soft and downy on both sides. Spikes solitary, very slender.—Native of Aleppo.

 Hardy

Hardy in our gardens, but it rarely flowers, unlefs, as Miller fays, it be confined in a pot. The *ftem* is fquare, a yard high, purplifh, minutely hairy, roughifh to the touch, leafy, with numerous oppofite branches. *Leaves* from one to two inches long, nearly or quite feffile, ovate-oblong, or fomewhat elliptical, acute, finely and fharply ferrated, entirely clothed with fine, fhort, denfe, hoary pubefcence. The *flowers* we have never feen. This fpecies feems neareft akin to the *fylveftris*.

6. M. *fylveftris*. Horfe Mint. Linn. Sp. Pl. 804. Engl. Bot. t. 686. Fl. Dan. t. 484. (M. villofa; Sole Menth. t. 1 and 2. M. rotundifolia; Sole Menth. t. 4. Menthaftrum; Ger. em. 684. Riv. Monop. Irr. t. 51. f. 1. Camer. Epit. 479. Fuchf. Hift. 292. M. hortenfis fecunda; ibid 298.)—Leaves acute, with tooth-like ferratures, chiefly downy beneath. Spikes hairy, flightly interrupted. Bracteas awl-fhaped.—Native of wafte ground, in rather moift fituations, throughout Europe, flowering, like moft of the genus, towards autumn. The *ftem* is from two to four feet high, fquare, fhaggy with hairs pointing downwards. *Leaves* feffile, of a grey and hoary afpect, whitifh underneath, with a ftrong difagreeable fcent for the moft part, though fome German and Swifs varieties are faid to be agreeably fragrant. Their fhape varies greatly, from oblong, or ovate, to a very broad, almoft orbicular, figure, as may be feen by the different figures above cited. The *fpikes*, folitary at the end of every branch, are thick, various in length, confifting of crowded, many-flowered, hairy *whorls*, with long, linear, acute, hairy *bracteas*, the lowermoft of which are broadeft. *Flower-ftalks* covered with clofely deflexed hairs. *Calyx* all over hairy, with long fharp teeth. *Corolla* pale lilac, hairy, twice as long as the calyx. *Stamens* occafionally longer or fhorter than the corolla, generally the latter.

We have from Switzerland, under the name of *M. fuavis* of Hoffmann, a narrow fharp-leaved variety of this; and from Pyrmont, one with broad ovate leaves, as *M. gratiffima* of Ehrhart, fee Hoffm. Germ. for 1791. 203; both have very hoary fpikes. We prefume the latter is the identical *M. fuaveolens*, Ehrh. Beitr. fafc. 7. 149, but the fynonyms there given all belong to the real *rotundifolia*, than which nothing can lefs deferve the name of *fuaveolens*. Willdenow quotes Ehrhart, with doubt, but rightly, under his own *nemorofa*, which is merely the ovate variety of *fylveftris*. The *gratiffima* of Willdenow is a repetition of the fame.

7. M. *niliaca*. Egyptian Mint. Jacq. Hort. Vind. v. 3. 46. t. 87.—Leaves ovate, acute, ferrated, hairy on both fides; paler beneath. Spikes clustered. Stamens much longer than the corolla, fmooth.—Native of Egypt. As Vahl and Willdenow adopt this fpecies, and we have feen no fpecimen, we would not prefume to refer it abfolutely to the laft, but we are much perfuaded that it is a mere variety. Jacquin defcribes the *leaves* as villous, though green on both fides; Vahl fays they are, in the wild plant, foft and hoary. The length of the *ftamens*, though ftriking, is by no means to be relied on for a fpecific character.

8. M. *glabrata*. Smooth Spiked Mint. Willd. n. 6. Vahl. Symb. v. 3. 75. (M. kahirina; Forfk. Ægypt-Arab; 213.)—"Leaves ftalked, ovato-lanceolate, ferrated, fmooth. Flowers in whorled clufters."—Found by Forfkall about Cairo in Egypt. The whole *plant* is faid to be fmooth. *Leaves* half an inch (we prefume) in breadth, dotted beneath. *Clufter*, or *fpike*, terminal of courfe. *Whorls* with nine umbellate flowers at each fide. *Bracteas* linear, the length of the whorls. *Stamens* fhorter, and *ftyle* longer, than the corolla.—Our account is taken from Willdenow, who copies Vahl. The latter examined Forfkall's fpecimen.

9. M. *rotundifolia*. Round-leaved Mint. Linn. Sp. Pl. 805. Engl. Bot. t. 446. (M. crifpa; Linn. Sp. Pl. ed. 1. 576. M. fylveftris; Sole Menth. t. 3. Menthaftrum anglicum; Riv. Monop. Irr. t. 51. f. 2. M. niveum anglicum; Ger. em. 684.)—Leaves elliptical, obtufe, rugged, crenate, villous beneath. Spikes interrupted, fomewhat hairy. Bracteas lanceolate.—Native of Germany, Switzerland, and England, in wafte marfhy ground. With us it is rather rare. In a variegated ftate, as defcribed by Gerarde, it often occurs in gardens, and is fometimes almoft entirely white, like blanched endive. This, which Mr. Sole unaccountably miftook for the *fylveftris*, is totally diftinct from every variety of that fpecies. The invariably fhort, roundifh, convex, and obtufe *leaves*, rugofe, of a dark grafs green, (not grey or hoary,) above; ftrongly reticulated with very hairy veins, but not hoary, beneath; and the very peculiar ftrong fmell, and vifcidity, of the whole plant, mark it with fufficient precifion. The *fpikes* are often clustered or panicled, more or lefs interrupted. *Bracteas* ovate, fharp-pointed, prominent. *Flower-ftalks* clothed with deflexed hairs. *Calyx* fhort, bell-fhaped, hairy all over, with long, fharp, coloured teeth. *Corolla* much like that of *fylveftris*. *Stamens*, as far as we have obferved, always longer than the petal.

Mr. Sole greatly commends this mint for its ftimulating refrefhing virtues, to which we can readily give credit, on account of its powerful fcent, well compared by that writer to a mixture of volatile falt of amber, camphor, and mint. He found it of great ufe in *chlorofis*, and not without fome effect in epilepfy. He miftakes however in thinking it the "true *Menthaftrum*, or Wild Horfe Mint, of the fhops." That plant of Dale's *Pharmacologia*, 159, our beft authority, is certainly the *fylveftris*; defcribed above. The *Mentha fylveftris* of Dale, as well as of Sole, is our *rotundifolia* here defcribed. This is the more important to be obferved, as the plants are probably very different in qualities.

10. M. *viridis*. Spear Mint. Linn. Sp. Pl. 804. Engl. Bot. t. 2424. Woodv. Med. Bot. t. 170. Sole Menth. t. 5. (M. romana; Ger. em. 680.)—Leaves feffile, lanceolate, acute, naked. Spikes interrupted. Bracteas briftle-fhaped, more or lefs hairy, as well as the teeth of the calyx.—Native of moift meadows, in various parts of Europe. In gardens it is fufficiently well known, by the names of Spear Mint, and Mackerell Mint, and is the *Mentha*, fimply fo called, of the fhops, the firft fpecies in Dale's *Pharmacologia*; being the only kind, except Peppermint next mentioned, retained in the moft recent London *Pharmacopeia*.—There are however feveral remarkable varieties of this fpecies, wild in England, whofe flavours and qualities differ from the beft or cultivated kind; though the latter is alfo a native of the fouthern parts of our ifland. The *ftems* are two or three feet high, erect, fmooth, with fharp angles, branched, often purplifh. *Leaves* feffile, lanceolate, acute, fharply ferrated, or in fome cafes toothed, fmooth, except an occafional hairinefs beneath. They are ftrongly veined, and in the varieties juft alluded to, they are confiderably rugofe, as well as of a broader and fhorter figure. In an exotic variety, whofe hiftory is given in Tranf. of the Linn. Soc. v. 5. 187, 188, and from which the defcription of Miller's *rubra*, n. 9, of his 8th edition, was made, the *leaves* are broadly ovate, with long wavy teeth, almoft like *M. crifpa*, hereafter mentioned. The *fpikes* are always more or lefs interrupted, tapering. *Bracteas* awl-fhaped, very flender at the point, keeled, roughifh, fometimes three-cleft, the lower and larger ones moftly affuming an ovate form. *Flower-ftalks* always fmooth, round and fhining. *Calyx* ribbed,

ribbed, tapering at the base, and equally smooth and naked in that part, but the teeth are fringed, more or less conspicuously, even in the garden variety, and very copiously in the more common wild ones, with hoary hairs. The *corolla* is smooth. *Stamens* various in length.

This species may be known, in all cases, from the *sylvestris*, with which some of its varieties have often been confounded, by the invariable smoothness of its *flower-stalks* and base of the *calyx*. The varieties with shorter rugose *leaves*, and most hairy *calyx-teeth*, have the most strong and disagreeable flavours, and are not fit for the uses of the table. Another variety has been sent us by the Rev. Dr. Muhlenberg, from Pensylvania, of a diminutive stature, with ovate *leaves*, not an inch long at the utmost, but in every essential character agreeing with the above.
